This shortage of coke is no new thing. For many years past, the smelting industry of the Boundary region has been handicapped by an uncertain supply of the necessary fuel, and ineffectual efforts have been made by the Government of Canada and the officials of the Canadian Pacific Railway to surmount the difficulty, but every effort has failed to effect a permanent improvement, simply because Mr. J. J. Hill controls the Crow's Nest Pass mines, and, in fact, the coal industry of the adjacent region. Moreover, as he controls the railroad that takes the coke from the Crow's Nest to Montana, it has been more profitable for him to send the coke to Montana than to the smelters of the Boundary, because in the one case he gets the profit on the coke, and in the other case, he gets the profit on both the coke and the freight. Officially, he is stated to own only 35% of the stock of the Crow's Nest Coal Co., but as a matter of fact, this interest, together with that of those allied with him, has enabled Mr. Hill to do pretty much as he pleases. Incidentally, it may be mentioned that while there are deposits of coking coal other than those now being exploited, these are not available for the Canadian Pacific Railway or the Government of Canada, because Mr. Hill owns blocks of land commanding access to them. In short, Mr. Hill has got the coking coal of the Northwest under his thumb.

Another interesting episode throwing light upon the monopoly of natural resources and the interference with economic laws, is presented by the experience of the Alaska-Treadwell Mining Co. As is generally known, this mining company and its two neighbors on Douglas island have depended for their fuel-supply on the coal of Nanaimo, on Vancouver island. Last year there was a strike, and the big Alaska-Treadwell stamp-mills were shut down for several months. To prevent a repetition of this experience, the manager has arranged to use oil; and it is a fact that this oil, which comes all the way from southern California is so much cheaper as a fuel than the coal from the comparatively neighboring island of Vancouver, that a saving of \$100,000 per annum will be effected by using oil. The Vancouver coal used to cost from \$1.75 to \$5, delivered, and from these figures it can be judged how cheaply oil can be brought from Lower

California to Douglas island. Incidentally, it may be mentioned that the oil steamers pull the barges laden with concentrate from the Alaska-Treadwell, Mexican United, and Alaska-Mexican mills, consigned to the smelter at Tacoma. This back freight helps to diminish the cost of carrying the oil. Such incidents go to prove that if you want to study economics, do not go to the library, but seek an interview with the representative of the particular railroad company that controls the politics, the resources, and the business of your habitat.

Greenwater.

IN THE EARLY PART of this year we referred to the copper mines of the Greenwater district, and ventured to emphasize the fact that the condition of their development and the proof of their value were wholly insufficient to warrant the tremendous amount of mine promotion and stock speculation then in progress. It is not popular to depreciate mining activity of any kind, and it is rendered unpleasant by the comment of papers committed to the encouragement of stock gambling. At the time of our former criticism, a paper at Los Angeles called *The Mining Review*, undertook to lecture us on the supposed unfair treatment of a promising young mining district. It is not with any particular satisfaction that we can state that the logic of events has confirmed our comment on Greenwater. Incidentally, our informant, Mr. James W. Abbott, is wholly justified; the incident is now to his professional credit. During the past 10 months, the work of exploration has been pushed vigorously; many shafts have been sunk, and at least a score of them have reached a depth varying from a hundred to 600 feet. From the bottoms of the deepest openings, cross-cuts and drifts have tested the indications of ore. Despite this energetic exploration, the results have been distinctly disappointing. A glance at the dumps throughout the district will show that no large bodies of pay-ore have been cut, and the present condition of the prospects that were expected to become mines, is depressing. Most of the smaller companies have ceased work entirely, and the larger companies are employing only a few men. At the present time there are hardly 20 men doing work underground in the entire district, as against no less than a hundred a few months ago. Two or three carloads of ore have been shipped, but there is no longer any pretense that large orebodies have been found. Almost without exception, the lower levels from the prospect shafts have cut no ore at all, or material even less promising than that seen at the surface. In consequence, the shares of the various companies are quoted at about one-tenth the price of six or eight months ago. The camp is losing its population, and is likely to become almost deserted in a few weeks. The larger companies controlled by Patsy Clark and Schwab are said to be looking for mining claims in other localities, with a view to giving their stockholders another speculative opportunity, and incidentally of adjusting matters so as to avoid the expostulation of those that have suffered by putting their money into these unfortunate schemes.

By the Way.

In a recent address before the British Association for the Advancement of Science, Mr. Silvanus P. Thompson said:

We must not delude ourselves with imagining that the happiness and welfare of mankind depend only on its material advancement, or that moral, intellectual, and spiritual forces are not in the ultimate resort of greater moment. But if the inquiry be propounded, what it is that has made possible this amazing material progress, there is but one answer that can be given—science. Chemistry, physics, mechanics, mathematics, it is these that have given to man the possibility of organizing this tremendous development. And the great profession which has been most potent in applying these branches of science to wield the energies of Nature and direct them to the service of man has been that of the engineer. Without the engineer, how little of all this activity could there have been? And without mathematics, mechanics, physics, and chemistry, where was the engineer?

If in looking over this England of Edward the Seventh we try to put ourselves back into the England of Edward the Sixth, we must admit that the difference to be found in the social and industrial conditions around us are due not in any appreciable degree to any changes in politics, philosophy, religion, or law, but to science and its applications. If we look abroad, and contrast the Germany of Wilhelm the Second with the Germany of Charles the Fifth, we shall come to the like conclusion. So also in every one of the progressive nations. And it is precisely in the stagnant nations, such as Spain or Servia, where the cultivation of science has scarcely begun, that the social conditions remain in the backward state of the Middle Ages.

In engineering, above all other branches of human effort, we are able to trace the close interaction between abstract science and its practical applications. Often as the connection between pure science and its applications has been emphasized in addresses upon engineering, the emphasis has almost always been laid upon the influence of the abstract upon the concrete. We are all familiar with the doctrine that the progress of science ought to be an end in itself; that scientific research ought to be pursued without regard to its immediate applications; that the importance of a discovery must not be measured by its apparent utility at the moment. We are assured that research in pure science is bound to work itself out in due time into technical appliances of utility, and that the pioneer ought not to pause in his quest to work out potential industrial developments. We are invited to consider the example of the immortal Faraday, who deliberately abstained from busying himself with marketable inventions arising out of his discoveries, excusing himself on the ground that he had no time to spare for money-making. It is equally true, and equally to the point, that Faraday, when he had established a new fact or a new physical relation, ceased from busying himself with it, and pronounced that it was now ready to be handed over to the mathematicians. But, admitting all these commonplaces as to the value of abstract science in itself and for its own sake, admitting also the proposition that sooner or later the practical applications are bound to follow upon the discovery, it yet remains true that in this thing the temperament of the discoverer counts for something. There are scientific investigators who can not pursue their work if troubled by the question of ulterior applications; there are others, no less truly scientific, who simply can not work without the definiteness of aim that is given by a practical problem.

There is, however, another aspect of the relation between pure and applied science, the significance of which has not been hitherto so much emphasized, but yet is none the less real—the reaction upon science and upon scientific discovery of the industrial applications. For while pure science breeds useful inventions, it is none the less true that the industrial development of useful inventions fosters the progress of pure science. No one who is conversant with the history, for example, of optics can doubt that the invention of the telescope and the desire to perfect it were the principal factors in the outburst of optical science which we associate with the names of Newton, Huygens, and Euler. The practical application, which we know was in the minds of each of these men, must surely have been the impelling motive that caused them to concentrate on abstract optics their great and exceptional powers of thought. It was in the quest—the hopeless quest—of the philosopher's stone and the elixir of life that the foundations of the science of chemistry were laid. The invention of the art of photography has given immense assistance to sciences as widely apart as meteorology, ethnology, astronomy, zoology, and spectroscopy. Of the laws of heat, men were profoundly ignorant until the invention of the steam engine compelled scientific investigation and the new science of thermodynamics was born.

The history of electric telegraphy furnishes a very striking example of this reflex influence of industrial applications. The discovery of the electric current by Volta, and the investigation of its properties, appear to have been stimulated by the medical properties attributed, in the preceding 50 years, to electric discharges. But, once the current had been discovered, a new incentive arose in the dim possibility it suggested of transmitting signals to a distance. This was certainly a possibility, even when only the chemical effects of the current had yet been found out. Not, however, until the magnetic effects of the current had been discovered and investigated did telegraphy assume commercial shape. But no sooner had the telegraph become of industrial importance, with telegraph lines erected on land and submarine cables laid in the sea, than fresh investigations were found necessary; new and delicate instruments must be devised; means of accurate measurement heretofore undreamt of must be found; standards for the comparison of electrical quantities must be created; and the laws governing the operations of electrical systems and apparatus must be investigated and formulated in appropriate mathematical expressions. And so, perforce, as the inevitable consequence of the growth of the telegraph industry, and mainly at the hands of those interested in submarine telegraphy, there came about the system of electrical and electromagnetic units.

In considering this reflex influence of the industrial applications upon the progress of pure science, it is of some significance to note that for the most part this influence is entirely helpful. There may be sporadic cases where industrial conditions tend temporarily to check progress by imposing persistence of a particular type of machine or appliance; but the general trend is always to help to new developments. The reaction aids the action; the law that is true enough in inorganic conservative systems, that reaction opposes the action, ceases here to be applicable, as indeed it ceases to be applicable in a vast number of organic phenomena. It is the very instability thereby introduced which is the essential of progress. The growing organism acts on its environment, and the change in the environment reacts on the organism—not in such a way as to oppose the growth, but so as to promote it. So is it with the development of pure science and its practical applications.

Personal.

S. F. EMMONS is at Denver.

E. W. BYRDE is in the French Sudan.

F. W. BRADLEY is at Elk City, Idaho.

ARTHUR S. DWIGHT is in the Southwest.

ERNEST CRAIG is at Cooney in New Mexico.

STEWART RAWLINGS is here from Durango, Mexico.

J. R. BLAKE, of New York, is on a visit to California.

COURTENAY DE KALB spent a few days in San Francisco.

GEORGE L. HOLMES has been examining dredging ground in Colorado.

E. A. H. TAYS has opened an office in the Jacobson Bdg., at Denver.

AUGUSTUS J. BOWIE is in San Francisco, on his return from Japan.

FRANK H. TEATS has opened an office in the Jackson Bdg., Denver.

WILLIAM CAMPBELL, of Columbia University, was here for a few days.

FRANK C. LORING has opened an office at 20 Adelaide St., East Toronto.

H. FOSTER BAIN, State Geologist of Illinois, was in San Francisco recently.

A. M. CAMPBELL has opened an assay-office at 1417 Lawrence St., at Denver.

T. F. JAMES is manager for the Belen Mining Co., at Cumpas, in Sonora, Mexico.

S. F. PARISH has moved from Tonopah to 406 Citizens' National Bank Bdg., Los Angeles.

GEORGE OTIS SMITH, the Director of the U. S. Geological Survey, was in San Francisco this week.

GEORGE W. MYERS, of the Chrome Steel Co., has returned to his old office at 724 Kohl Bdg., San Francisco.

ARTHUR E. PETTIT has arrived in Wyoming from London, to examine the Penn-Wyoming copper mines.

FRANK R. HALL has resigned as engineer to the New York & Honduras Rosario Mining Co., and is returning home.

GEORGE D. LOUDERBACK has returned to the University of California, on the completion of geological work near Santa Barbara.

ARTHUR C. NAHL, manager for the Progreso Mining Co., at Triunfo, Lower California, Mexico, is on a visit to his home at Berkeley.

C. S. NEWCOMB has been appointed superintendent of the cyanide plant of the Dolores Mines Ltd. in Chihuahua, succeeding ROBERT CLARKE, who resigned.

EDWARD A. NIS has resigned as mine superintendent of the New York & Honduras Rosario Mining Co., to be general superintendent for the same company.

A. H. BUCK, after nine years in Mexico and Central America, is now a resident of Joplin, Missouri. Mr. Buck is associated with M. S. Parker in the firm of Parker & Buck, their office being at 309 Bartlett Bdg., Joplin.

L. VOGELSTEIN & Co., New York, give the following figures of German consumption of foreign copper for the months January to July, 1907 :

Imports of copper	73,732 tons
Exports "	4,969 "
Consumption "	68,763 "

As against consumption during the same period in 1906 of 68,659 tons. Of this quantity 57,532 tons were imported from the United States.

Dividends.

On September 4 the Bunker Hill & Sullivan Mining & Concentration Co. paid dividend No. 120 of \$180,000. This makes the amount of dividends paid since January 1, \$1,620,000, and the total to date \$9,486,000.

General Mining News.

ALASKA.
KETCHIKAN.

Some good ore has been found near the mouth of the Chickamin river by J. E. Kydig and E. K. Turner. The last ship down carried 500 tons of Rush & Brown ore and 2,500 tons from the Jumbo, consigned to the Tye smelter at Ladysmith.—Twenty-five men are employed at the Rush & Brown mine, and a larger force could be worked to advantage if proper transportation facilities were available for handling the ore. As it is, the bunkers are full and the mine could produce 100 tons per day.—P. L. Peterson and other owners of the Eagle copper claims at Boca de Quadra, have bonded the property to E. M. Aldrich of Spokane, who will explore it thoroughly.—The Goodro & Thomas tunnel is in 60 ft.—A vein carrying chalcoppyrite is being developed by Daniel Nelson on the Snowbird claim, near Kasaan village.

ARIZONA.
COCHISE COUNTY.

If the metal market does not improve, it is thought that some of the big companies operating in the Warren district will reduce their working forces and devote more attention to development. The Copper Queen will probably pursue this policy within 60 days if the price of copper does not go up.—The Wolverine & Arizona drift from the Higgins shaft has struck ore and the management is optimistic regarding the property.—At the Copper Queen smelter, only six furnaces are running, with four converters handling the matte. The equipment includes 10 furnaces, but only nine have been run at one time. The closing down of all but six is to enable the repair gang to overhaul the furnaces, and the lower price of copper probably has something to do with this curtailment of production. About 150 men were laid off, mostly Mexicans.—Four furnaces are working at the Calumet & Arizona smelter.

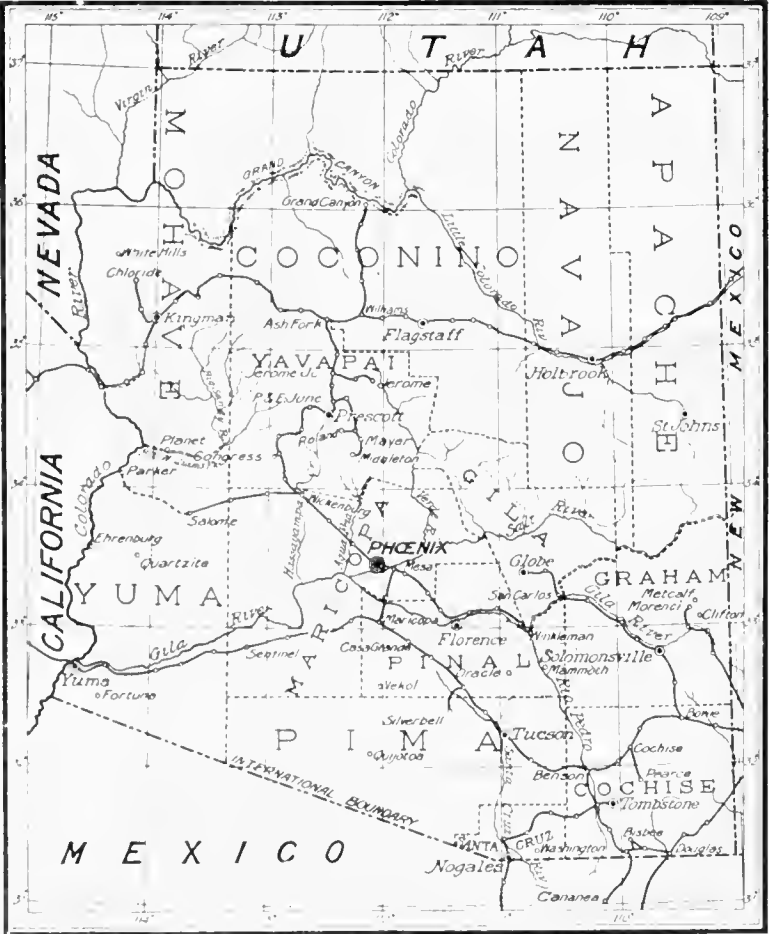

At Johnson, it is understood that the Arizona Consolidated M. Co. will erect a new head-frame and hoist on the Mammoth property, west of the Copper Chief. This property was leased and worked for some time by Bob Mackay, and some good ore was produced.—A new 40-hp. hoist has arrived for the Empire. The main shaft is down about 250 ft. and two shifts are sinking. At the 225-ft. level, a cross-cut has been driven 150 ft.—The Cochise Mining Co.'s shaft is down 600 ft., still in blue limestone.—Ore is being mined and stocked at the Magazine mine, of which H. J. Clifford is manager.

GILA COUNTY.

The Saddle Mountain M. Co., operating at Christmas, in the southwestern part of this county, has ceased work temporarily, pending the arrival of coke for the smelter, and the repair of portions of the plant. About seven carloads of matte have been shipped each month. Burnett Goodwin is the assistant manager.—The washouts along the line of the Gila Valley, Globe & Northern have been the worst ever experienced. All rail communication has been cut off and the wires have been down, but fortunately the Globe smelter had enough fuel on hand to enable it to run without interruption.—The Old Dominion produced more copper last month than ever before in its history, the smelter output being about 3,500,000 lb. Underground, development is progressing without interruption. The cross-cut in block No. 6 on the 14th level is being driven through. The width of No. 1 sulphide vein as here exposed is only seven feet, but the ore runs high in sulphur and iron. No. 2 vein will be encountered soon. A good deal of water

is coming in. The winze from the 14th level is 150 ft. deep.

The Gem shaft of the Globe Consolidated is 920 ft. deep and still in diorite. In the Globe-Boston shaft a station is being cut at the 782-ft. level, and a 500-gal. Prescott pump will be installed, as water was encountered in the bottom of the shaft, at 789 ft.—From the Globe-Boston shaft, two cross-cuts will be driven, one to the northwest, by which the vein that was worked on the 450-ft. level is expected to be cut, and another to the southwest, which will be the first cross-cut to go under Big Johnny gulch, and will penetrate Buffalo hill and connect with the Buffalo cross-cut of the Gray mine of the Old Dominion, at the 740-ft. level, making a cross-cut 2,200 ft. long.—Shipments of ore from the Gibson to the Old Dominion smelter have fallen off a little, and will probably total about 1,200 tons for the past month. A large force, 240 men, is employed. The new

Map of Arizona.

three-compartment shaft is down 150 ft., and the head-frame is completed.—The lower workings on the Arizona National property have been temporarily abandoned while cross-cuts are being driven in opposite directions from the shaft at a depth of 125 ft., to determine what has become of the remainder of the vein. The formation is rather puzzling as it seems that the vein splits and dips both ways from the shaft. About 50 ft. of cross-cutting has been done so far and there is no country rock in sight. The ore appears to be getting richer in the west cross-cut, according to recent reports from the mine. At the bottom of the shaft, which is 200 ft. deep, the country rock appears to be dipping in opposite directions from the shaft. Two shifts are working at the mine.—The Oro Grande M. Co., owned by Globe men, has been developing a group of copper claims on Upper Mineral creek in this county, adjacent to the Parish property. They have a shaft down 110 ft., and are driving both ways on a vein five feet wide.

GRAHAM COUNTY.

The Shannon Copper Co. ends its fiscal year with the last day of August. It is expected that the net earnings for the year will be about \$800,000, after all charges, including the

retirement of \$100,000 bonds. This would be about \$2.66 per share upon the outstanding 300,000 shares. The average price for copper obtained during the past 12 months was about 22c., the highest being a trifle over 25c. Over a similar period a year ago, the net earnings were only \$333,000.

MOHAVE COUNTY.

A gasoline hoist has been shipped to the Redemption-Clyde mines at Chloride. It is reported that R. J. Ferguson has succeeded in financing these mines, and work will be pushed.—Several of the directors of the Benedictine company have been in Kingman, from Los Angeles, to settle the claims against the company, amounting to about \$10,000. W. P. Carr will be in charge of the work at Cedar.—J. L. Whitney and a force of men are sampling the McCracken mines at Signal, to test the ore for amenability to concentration and cyanidation.—A new hoist and pump have been installed at the K. P. mines in I X L basin, and sinking will be resumed. H. M. Bowen is the manager.—E. J. McNulty of Mineral Park is in charge of the Aztec Turquoise M. Co.'s property; a good many gems were shipped during the past year.—The work of remodeling the Cupel mill is nearly completed. Good concentrating ore is being broken in the east drift of the De la Fontaine mine.—A 15-hp. gasoline hoist has been shipped to the Idaho mine at Cerbat. A magnetic separator may be installed to handle the ore at the Vanderbilt mill. John Boyle, Jr., is in charge.—The drift on the vein at the Stockton Hill property has been driven 2,300 ft., and a long and continuous orebody has been exposed.

PIMA COUNTY.

Reports have it that the Heinze interests have secured control of the Helvetia Copper Co. Representatives of these people have recently been inspecting the property. A great deal of money has been expended in the development of this property. There is a narrow-gauge railroad and a 200-ton smelter. Recently a good strike was made in a tunnel between the Copper World and the Isle Royale shafts.

PINAL COUNTY.

The Roy Copper Co. has ceased operations, and 300 men have been thrown out of employment. Various reasons are assigned to this action, among which are the non-completion of the big concentrating plant at Kelvin, seven miles distant, and the attempt of the Western Federation of Miners to unionize the camp. The company employees give out the statement that work at the mine is ahead of work at the mill, and the shut-down is for this reason.

YAVAPAI COUNTY.

(Special Correspondence).—The Haggott Giraud Co., consulting engineers, of Prescott, have been placed in charge of the development of the Jerome-Verde Copper Co.'s property, and active work will be started about September 15. W. P. Dykema, of Michigan, is in charge. A complete hoisting plant was ordered several weeks ago.—T. C. Campbell, mine manager, reports a strike of ore in the new shaft of the Jerome Mines Development Co. at a depth of 27 ft. from the surface. He states that there is a lens of sulphide ore occurring in the schist, and that it was entirely unlooked for, as their diamond-drill had demonstrated ore at this point to lie at a depth of 527 ft. This company expects to put in a complete hoisting plant.—The workings on the 1888 claim, belonging to the Hull Copper Co., have been cleared of water and muck, and carefully retimbered. Driving will be commenced, to connect with the Dillon tunnel.

Jerome, Sept. 4.

(Special Correspondence).—Several companies are operating on Copper creek in the Eureka district. The men comprising the companies are many of them experienced miners. Good machinery has been installed during the past year, and all of the surface improvements are suggestive of permanence. Several hoisting plants are in operation, as well as air-compressors. A new wagon-road is being built from the Copper Creek road to the Mammoth group of mines, where work will be started soon. Miners are coming into the district daily in search of claims, and the country for miles around is dotted with locations. A

little over a year ago operations were started in the district by the Giroux & Hook syndicate, which now holds by right of location a stretch of mineral country six miles long by four miles wide. The syndicate has a large air-compressor in operation, as well as two hoisting plants, and is running five tunnels into the mountain, the lower one of which will reach a depth of between 400 and 500 ft. Following this work, the American Mines & Exploration Co. has bonded the Voge and Hise groups, consisting of over 50 claims, upon which work is being prosecuted. The prospect for the development of a good mine here is equally as encouraging as in the Giroux & Hook holdings. Preliminary surveys for a railroad into the district have been made and thousands of dollars have been spent in constructing wagon-roads into the different camps.

Prescott, Sept. 5.

Two tunnels are being driven on the Houston-Arizona property, one on the Copper King claim and one on the New Departure. W. M. Owens is in charge of the work.—The hoist on the Mexican silver mine is ready to run. Oscar Jennings is the superintendent.—M. D. Gaylord recently examined the McNeill property near Vulture.

CALIFORNIA.

CALAVERAS COUNTY.

The miners' strike in Angels has been declared off, by an affirmative vote of 64, as opposed to 24, and the Coleman proposition of 9 hours per day has been accepted by underground men. The Lightner mine has started work again and the Utica will be unwatered, and the Angels mine will be working in a few days.

NEVADA COUNTY.

A good deal of building material and mining has been arriving in Grass Valley, for the North Star mine; this includes a 500-hp. motor, and three carloads of redwood tank material for the enlarged cyanide plant.—A 25-hp. gasoline hoist has been purchased for the Aurora mine on Randolph flat. The shaft will be sunk to the 300-ft. point, and a pump will be put in at once. H. B. Skewes is the superintendent.—The Prosper mine, on Canada hill, just above the old Canada Hill mine, is being steadily developed by the owners. H. A. Ball, of the Banner mine, has bonded the property. This is an extension of the West Side property that is being opened by a Tonopah syndicate. The lower tunnel is in 150 ft., and a shaft is down 84 ft.—Good progress in development work is being made at the Banner mine, especially in extending the south drift on the 900-ft. level, which is being run toward the old pay-shoot.—A new dynamo, transformers, etc., have arrived at Nevada City for the Alaska mine at Pike City. The power-line from the Rome power-house will soon be completed, and operations at the mine will commence.—A good strike has been made in the Morning Star mine at Badger hill in the old Cherokee district, near Patterson. The ore was found in a new vein that was opened by a cross-cut to the west of the shaft, on the 60-ft. level, and again struck on the 100-ft. level. The main shaft is down 185 ft., and will be continued to the 500-ft. point. Five of the 10 stamps are dropping in the mill. E. E. House is superintendent, and Frank Bigelow, foreman.

PLACER COUNTY.

The Peckham Hill property has recently been examined, with a view to extending the 1,500-ft. tunnel, the face of which is now near the old Blue Gravel shaft.

SHASTA COUNTY.

(Special Correspondence).—The Noble Electric Steel Co. has been recently incorporated to enlarge and operate the smelting works at Heroult. H. H. Noble is president and C. B. Morgan secretary of the company. The work that has been already done at the smelter has demonstrated to the entire satisfaction of those interested that the iron ores in this district can be profitably smelted under the conditions prevailing in Shasta county. Plans are accordingly being rapidly made for the development of this industry on a larger scale. The mine is being actively developed and more property is being secured. Work is proceeding rapidly on a tramroad which is to provide cheap transportation

from the mine to the smelter. This will be about $1\frac{1}{2}$ miles in length. At the smelter preparations are under way for the erection of a plant for the manufacture of electrodes and also for the enlargement of the charcoal plant. In the meantime the present furnace will be used for the manufacture of ferro-silicon. It has been decided to temporarily abandon smelting pig-iron, owing to the high cost of freighting by wagons until the railroad is finished, and because an adequate supply of electrodes cannot be obtained until they are made on the ground. At the present time a new furnace is being designed for the smelting of pig-iron, and this will be installed as soon as the necessary transformers and other machinery can be delivered.—In the Centerville district considerable activity continues and promising developments are progressing. The Monte Cristo group is being developed by A. Monette and associates. This property adjoins the Yankee John mine, which has been undergoing vigorous development. A recent shipment from the latter property assayed \$1,400 per ton. As soon as the new drifts get under the old workings and the known ore-shoots, good results may be expected. With the present development this district should soon produce considerable shipping ore.—From the Little Nellie mine on the Iron Mountain railroad, regular shipments of high-grade ore are being made to the Keswick smelter.—The narrow-gauge railroad constructed by the Mammoth Copper Co. to Quartz hill, to ensure a constant supply of silicious ore is completed, and as soon as the bunkers are finished regular shipments will be commenced.

Redding, Sept. 5.

(Special Correspondence).—A. E. Monette and associates of Nevada have bonded the Jim Long group in the Centerville district. The group contains five claims with small stringers of rich ore. A double-compartment shaft will be sunk and cross-cuts driven to intersect the lode.—The Pittsburg & Mt. Shasta G. M. Co. is shipping ore to Keswick. A 450-ft. lower tunnel is being driven to strike the vein at depth. In the old workings a rich shoot has been encountered in the drifts on the Remington vein. Edward McGrew is superintendent.—The Grizzly Gulch M. Co. is developing a good ore-shoot in the Truscott. The main vein is 8 ft. wide. E. P. Sherk is superintendent.—Large bodies of fair-grade ore have been developed in the Sugar Loaf. A good force of men are employed and a reserve of ore is being blocked out. George Graves is superintending operations.—The Great Western Co., operating the Afterthought mine and Ingot smelter, announces that work will shortly commence on a railroad from their properties to connect with the Bella Vista line.

Redding, Sept. 7.

The Gold Leaf M. Co. has secured the right of way over the Eureka Tellurium land for its trolley tram. Within a few weeks an electric locomotive will be hauling 100 tons of ore per day from the Gold Leaf mine to the ore bunkers at Middle Creek station. H. O. Cummins is manager for this company, and of the White Oak and Milton mines. Over 125 men are working in the Lower Springs district.—The big rock crusher is being set up at Kimberly. This machine will do coarse crushing preliminary to loading ore in the tramline buckets, for the smelter. The tramway should be finished within a month; William Raymond of Salt Lake has charge of the construction.—Work has commenced on the 8,000-ft. extension of the Holt & Gregg narrow-gauge railroad, to the Golinsky mine. This mine has been held under bond for a year, but there has been some dispute as to the possession of the ground where the tunnel starts, so no copper ore has been shipped for some months.

TRINITY COUNTY.

(Special Correspondence).—A 20-stamp mill and a cyanide plant have been installed at the Golden Jubilee, on Coffee creek. The vein is holding out well and some of the ore is rich and is being shipped to the Selby smelter. Much development is under way. W. L. Chapman is superintendent.—Three tunnels are in good ore at the Poeth. A shipment to the smelter went \$250 per ton. A ditch with a capacity of 350 in. is being dug from Boulder creek to furnish power for the surface machinery, which will soon be

installed.—A Philadelphia company has acquired a two years' bond on the Headlight, and is driving the lower tunnel to tap the main orebody at depth. The ore carries copper and gold and will be treated at the smelter.—At the Bonanza King, the mill is running at full capacity on excellent ore. The lower tunnels are being extended, the ore-shoot holding out well.—A four-foot vein of free-milling quartz has been struck in the lower level on the Keating. A new wagon-road is being built.—At the Dorleska a promising vein is being developed. The new plant was recently installed.—It is reported that the Brown Bear will shortly pass into the hands of the Bullychoop company. The Brown Bear was once one of the largest gold producers in this part of the State.

A crew of men is working claims northwest of Minersville, for James Hulme. An old channel of Trinity river can be traced on the ground.—Two pocket prospects are being worked near the Fairview, one by George Giddings on the Trinity river, five miles above the mouth of Stuart's fork, on a slate-porphry contact, and the other is worked by R. J. Laird, who has run a 75-ft. tunnel on a contact.

Carville, Aug. 30.

TUOLUMNE COUNTY.

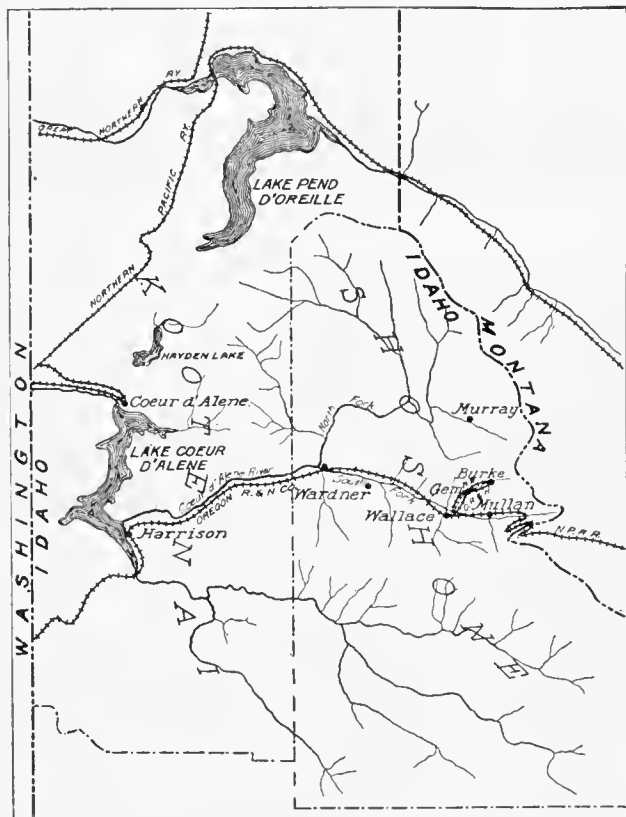

The Eagle-Shawmut M. Co. has purchased a 200-hp. Ingersoll-Sergeant air-compressor. A triplex electric pump is being erected on the 600-ft. level of the Shawmut mine.—Samuel Harris, representing La Fiesta G. M. Co., an English corporation that recently bought the Kanaka mines near Groveland, has ordered a 10-stamp mill from the Angels Iron Works.—The strike made last week in the Iron Spring mine, on Hunter creek, still holds. An 18-in. vein carries some good ore. The mine is owned by E. Caldwell and Thomas Armstrong of Santa Cruz.

IDAHO.

SHOSHONE COUNTY.

Mining claims within a few miles of Mullan, located by C. M. Delgrove and A. T. Davis, of Spokane, have been taken over by a mining and power company in Spokane. Articles of incorporation of the new company show the capital stock to be \$1,500,000. Work on the development of the 14 claims will be started at once. The concern will be known as the Copper Face M. & P. Co. The incorporators are: J. P. Webster, W. H. Honefenger, A. T. Davis, C. M. Delgrove, and W. S. Martin.—The lower tunnel, driven to cut at depth the Hunter vein, has broken into an orebody. The strike is considered one of the most important made in the Mullan district since the National strike. At last accounts the cross-cut, which is in 2,500 ft., has exposed 18 ft. of ore, 7 ft. of which is galena ore of good grade. The rest is low-grade ore, which will average between 6 and 7%. The strike is within 30 ft. of American Commander end line.—E. S. Clark, of the Mullan Investment Co., controlling the Daisy, Carney Copper, Derby, and Glen Metals, announced that shipping of ore from the property will begin at once. The Daisy, three miles east of Mullan, is a good looking proposition. Ore showings have been made there that are surprising. The upper tunnel on the Carney Copper has been driven in between 600 and 700 ft. They expect to strike the ore at a depth of 800 ft.—John H. Nordquist, president of the Idora Mining Co., says the first carload of ore will be shipped in a few days. This is the first shipment in 10 years. The ore will go to the Panhandle smelter at Ponderay.—The Independent Copper Co. has elected these officers to serve for the ensuing year: President, James Bean; vice-president and manager, J. H. Nordquist; treasurer, C. D. Miller. The directors are James Bean, J. H. Nordquist, Henry Nilberg, D. F. Clark, R. R. McCormick, August Matt, and H. Leithead.—The Surprise Mining Co. has completed the new concentrator building on that property on Pine creek, also the air compressor and the engine. The other machinery, including crushers, jigs, vanners, tables, and screens, is on the way and everything is in readiness for its installation as soon as it reaches Wardner. The mill will have a capacity of 75 tons per day, but it is so constructed that the capacity may easily be increased to 300 tons. The company has three new 350-lb. air-drills and five small machines for stoping. Shipments of ore will be

begun as soon as the mill is completed. The concentrates will be hauled by wagon to the Pine Creek spur of the Oregon Railroad & Navigation Co. M. J. Sinclair, one of the principal owners, is supervising the work.—Under the supervision of C. Horton Hart, the mineral and ore display in the Spokane Chamber of Commerce quarters promises to be the best in this part of the country, if not in the whole United States. Every mine tributary to Spokane will be asked to send 20 lb. of its ore, and fill out a blank descriptive of the ore and the mine it came from, the purpose being to promote the industry by showing the resources of the districts.—Negotiations have been completed with the Rex Mining Co. and individual stockholders of the mine whereby B. M. Francis, of Spokane, and several New York and Montana associates, secured 775,000 shares, the controlling interest in the property, paying \$225,000 for their holdings.

The Coeur d'Alene, Idaho.

The mine, near Wallace, will be opened at once. It has been idle for six years because of unsettled litigation. They will immediately put three shifts of men at work, open and remodel the concentrator, which has a capacity of 200 tons per day; install new hoisting machinery on the second ore-shoot in the lower tunnel and immediately commence to sink 300 ft. lower. A three-foot vein of shipping ore is in sight in the face of the old tunnel. Within a year the mine will be paying dividends. Thomas Jay, superintendent of the Monitor mine, will be superintendent.—By the sale of the Croesus, Mantle Fraction, and Bullion lode mining claims at public auction at Wallace, by the order of the district court, \$25,700 was realized, and the suit of Lee Mantle against H. L. Frank, Walter Blossom, and others for a partition of the claims was brought to a close. Mantle bought the claims, paying \$17,500 for the Croesus and \$4,100 each for the others. The value of the claims, which are situated in the Eagle mining district, is shown by the fact that the area of the Mantle fraction is only two acres. John H. Wourms, E. P. Candee, and J. A. Reeves were appointed referees to partition the interests.

The Tiger-Poorman mine at Burke will be closed down. This is one of the most famous of the old producers in the Coeur d'Alene, but is reported to be worked out. Some months ago it was supposed that a rich shoot of ore had been discovered on the 2,000-ft. level, but this has pinched out. A small force of men will be retained to carry on

prospecting, instead of the force of 150 men at present employed. The Tiger-Poorman was discovered in the early eighties, was sold in 1901 to the Buffalo Hump M. Co., and consolidated with the Empire State company, and in 1903 these were all taken over by the Federal M. & S. Co. The concentrator at Burke, with a capacity of 400 tons per day, but which has for some time been in a rather bad state of repair, has been closed.

NEVADA.

ESMERALDA COUNTY.

The production of Goldfield for the week ending September 7 was unusually light. Factors contributing to this decrease were the closing of the mines on Labor day, and the lack of shipments from the Mohawk and Combination mines. The Nevada Goldfield Reduction Works received 647 tons; Western Ore Purchasing Co., 919; total output, 1,566 tons, with an estimated value of about \$285,000. No ore was shipped to the smelters during the week. The settlement of the labor troubles will increase the output for the coming week.—The Nevada Goldfield Reduction Works received ore as follows: Mohawk-Combination, 336 tons; Little Florence, 134; Red Top, 145; Rodgers-Goldfield Syndicate, 32. Total, 647 tons. Total mill value estimated at \$80,875.—For the same week the Western Ore Purchasing Co. received consignments of ore as follows: Mohawk-Jumbo, 707 tons; Hayes-Monnette dump, 161; Florence L. & M. Co., 51. Total, 919 tons. Total mill value estimated at \$104,875.

The Little Florence is reported to have run onto a good shoot of ore on the 400-ft. level, about 225 ft. from the incline shaft. A new vertical shaft may be sunk from the crest of the hill, to the 500-ft. level.—The shaft on the Commonwealth ground is down 400 ft., and but little water has been encountered. The diamond-drill operations will soon be resumed. W. E. Meyers is the superintendent, and has 10 men under him. The foundations of the Florence mill have been completed, and the superstructure is being raised at the collar of the company shaft on the northeast slope of Red King hill. A cement-lined reservoir has been built above the mill, with a capacity of 350,000 gal. The mill will consist of two units of 20 stamps each, the stamps weighing 1,000 lb., and having a 6-in. drop. The ore-bins have a capacity of 500 tons. The sand and slime will not be separated, and there are many cyanicides in the Florence ore.

NYE COUNTY.

(Special Correspondence).—The Bullfrog Consolidated M. Co. of Nevada has secured control of the Silver King and Clara B. groups in the Bare Mtn. region. The groups contain eight claims. A tunnel will be driven on one of the cross veins. R. V. Perkins is general manager.—In the Gold Bullfrog, the vein in the cross-cut from the tunnel has widened to 8 ft. The 35-ton Standard mill has been installed and is ready for service. The first unit of the cyanide plant is being constructed.—At the Gold Bar the shaft is down 500 ft., with 4,860 ft. of underground work. Good ore is being developed in the lower levels. L. P. Bedford is general manager.—The new pump has been installed at the Montgomery-Shoshone. It will supply water for the mill from a pumping station one mile from Rhyolite. The Bush Brothers of this place have bonded the Orient group of six claims in the Ibex district.—The West Extension and Bullfrog Teddy are being examined by C. J. Moore. The company is planning to commence development work on both properties. The shaft on the west end of the Delaware claim of the West Extension will be sunk to the 200 level and a hoist will be installed. Drifts will be run to connect this shaft with the main working shaft on the other side of the hill.—At the Homestake King, a large body of fair-grade ore is being developed. The company has ordered a 20-stamp mill for the property.—At the Maysflower, the vein is holding out well and some rich ore is being developed. Driving is under way on the main ore-shoot.—At the Tramps Consolidated some ore is being blocked out, with considerable exploration work under way.

Rhyolite, Sept. 5.

OREGON.

JACKSON COUNTY.

Work is progressing at the Alta Consolidated property, near the State line. Frank Morrin is in charge. There are six claims in the group, a shaft is down 250 ft., and several hundred feet of work has been done. A 30-ton Huntington mill and cyanide plant are in operation. Frank Blevins is mine foreman.—James Milner of Los Angeles is in Ashland, looking for black sand propositions.

WASHINGTON.

OKANOGAN COUNTY.

(Special Correspondence).—Another vein, 27 ft. wide, has been crossed by the adit of the Palmer Mountain T. & P. Co., in Palmer Min., at a depth of 1,600 ft.—A blind vein 22 in. wide has been encountered on the 112-ft. level of the Olentangy mine, near Chesaw. The ore assays \$38 per ton in gold, silver, copper, and lead. Six men are employed installing a hoisting engine and air-compressor plant. The working force will be doubled within a month, and the company hopes to begin shipping ore within 90 days. John H. Arnold, of Columbus, Ohio, the president of the company, is visiting the mine.—At the Grant Consolidated mine, 18 men are employed. The lower adit is in over 300 ft.—The Ben Harrison mine is employing six men and has installed a new power hoist.—Water has been turned on at the Allen placers, on Mary Ann creek, and the management expects a big clean-up.—The Molson Mining Co. expects to start up its new mill on the Poland-China mine, about Sept. 5.—The Chelsea group, on Texas creek, Twisp district, has been bonded to D. H. Cramer, representing Ohio people, for \$25,000. The bond runs three years, with a stipulation requiring the vendee to drive 500 ft. of adit each year.

Republic, Sept. 2.

BRITISH COLUMBIA.

The deputy sent by the government to investigate the coke shortage, has visited Trail, Nelson, Kaslo, and Fernie, and will report on conditions as he found them, within a few days; the operators are hoping that this will lead to some prohibitions regarding the exportation of coke by the Crow's Nest Pass Coal Co.—During the week ending August 31, the Rossland mines shipped and crushed the following tonnage: Centre Star, 1,840 tons; Le Roi, 980; Le Roi No. 2, 315; White Bear, milled, 350 tons. Total, 3,485 tons of ore.—Le Roi sent its first consignment of ore to the smelter since a month ago, billing it to the Northport plant. The winze workings are being put in shape for stoping, and general development is proceeding.—The Centre Star shipments were curtailed by the limited capacity of the Trail smelter, but the ground is opened up so that the production can be greatly increased at short notice.—The White Bear sent a carload of concentrate to the Trail smelter, the result of putting 350 tons through the mill. William C. Fox, a large shareholder, recently visited the property.

The Trail smelter received 4,917 tons of ore during the week. In addition to the ore sent from Rossland, the following companies made shipments: Snowshoe, Phoenix, 1,736 tons; Victoria, Nelson, 97; Whitewater, Ainsworth, 151; Second Relief, 42; Arlington, Slocan, 34; St. Eugene, Moyle, 26; Arlington, Erie, 23; Vancouver, 21; Sunset, 21; Reco, Slocan, 18; Payroll, 18; Forget, 250 tons.—The smelter at Northport received 980 tons of ore during the week from Le Roi mine. The receipts of coke continue, and in a short time there may be sufficient to justify the restarting of the smelter.

The output of the Boundary district for the week was as follows: To Granby smelter from Granby mines, 8,843 tons; from Emma, 150 tons. To B. C. Copper Co.'s smelter from Mother Lode, 4,343 tons; from Snowshoe, 2,400 tons. To Dominion Copper Co.'s smelter from Brooklyn, 512 tons; from Idaho, 672; from Rawhide, 2,656; from Sunset, 1,295; from Mountain Rose, 210 tons. To Trail smelter from Snowshoe, 1,700 tons. To Nelson smelter from Emma, 30 tons. Total shipments for week, 22,811 tons. Total ship-

ments for year to date, 787,893 tons.—This week Boundary smelters treated ore as follows: Granby smelter, 13,180 tons; B. C. Copper Co.'s smelter, 6,525 tons; Dominion Copper Co.'s smelter, 5,345 tons. Total treatment for week, 25,050 tons, and for year to date, 774,296 tons.

The smelters in the different districts received ore as follows during the week: Boundary, 22,855 tons; Rossland, 2,728; east of the Columbia river, 2,290 tons. The different smelters received the following consignments: Granby, 8,993 tons; Greenwood, 6,743; Boundary Falls, 5,365; Trail, 4,895; Nelson, 115; Northport, Washington, 980; Marysville, 600 tons. Total, 27,671 tons of ore.

News comes to Vancouver of the strike of a large body of medium-grade ore in the 500-ft. Jane tunnel of the Britannia mine on Howe sound. The ore has already been cross-cut for 100 ft. Some good copper is showing in the cores obtained from the diamond-drill working on the Britannia.

An option has been taken on the Bella Coola mine for \$250,000. Some copper ore has been taken out of the tunnel.—Some samples of coking coal have been brought in from the north fork of Granite creek. A 200-ft. tunnel has been run on the seam. A Colorado company has a bond on the property.—The output of the Nicola Coal & Coke Co. will be 1,000 tons per day before the end of the year.—Ten men are employed at the Golden Eagle property near Volcanic Mtn., 12 miles from Grand Forks, which was recently bonded by Vancouver men. A good vein was struck at the 70-ft. point in the shaft.

MEXICO.

CHIHUAHUA.

The Granadena mill has resumed operation, after a two-week shut-down on account of lack of fuel. The capacity of the plant is about 80 tons per day.—The new hotel, being built by the company for the employees of the Minas Tecolotes y Anexas, is nearly completed.—The deal for the lease of the Palmilla mine has not been closed by Eugene Davis or G. C. Beekman who represent capital here, but work continues at the mine under the superintendence of P. W. K. Robertson.—The new 250-ton furnace of the Encinillas M. & S. Works of Sta. Rosalia, is to be erected at once, and a second one will be ordered. R. J. Morambert is the manager.—It is said that F. A. Heinze's engineers have been examining the Potosi mine and the properties of the Chihuahua Mining Co., all in the Sta. Eulalia district, with a view to purchase.—The Dwight Furness Co. has sold the San Gregorio mines to a New York corporation, together with an option on the San Gregorio railroad extending from El Chorro to Marfil. H. H. Miller represents the company.—Frank Holmes, manager for the Oxnam Prospecting Co., operating near Guazapares, has been made manager for the Palmarejo & Mexican Goldfield, Ltd., to succeed W. A. Pomeroy. Arthur E. Stillwell will bring a party of 80 shareholders in the K. C. M. & O. R. R., to Chihuahua in a special train, within two weeks. Later they will proceed to Mexico City.

ZACATECAS.

The Mazapil Copper Co., operating at Concepcion del Oro, in this State, is developing into a great copper property. The capitalization is \$6,000,000, and it is said that 60% of this amount has been paid out in dividends. Last year the mines produced 8,000,000 lb. copper, 750,000 oz. silver, and 10,000 oz. gold, and this will be increased greatly this year.

The company owns 2,000 *pertenencias*, and employs nearly 8,000 men. About 12,000 tons of copper ore are produced per month, and smelted at Concepcion del Oro, and 9,000 tons of lead ore, which is stacked, to be treated in the new lead smelter recently built at Saltillo, in Coahuila, which has a monthly capacity of 10,000 tons. The copper smelter will be enlarged to have a capacity of 1,000 tons per day, and a 150-ton net concentrating plant has been built at the mines. A 1,500-m. tunnel has been started, to tap the Arauzazu mines 200 m. below the present workings, which are about 500 ft. below the surface.—E. P. Merrill is the manager.

Special Correspondence.

Butte, Montana.

The Machinists Strike.—A Few Mines Suspend Work.—Discovery in the New Boston.—North Butte Extension.—Smelters Restrict Purchase of Ores.—Mining at 2,800 ft.—Operations on the Parrot.

The machinists of Butte twice within two days rejected, by an almost unanimous vote, the propositions of the mining companies to settle the strike and permit resumption of operations at all the mines. The machinists struck on August 1 for an increase of wages from \$1.50 to \$5. Some months ago the mining companies offered them \$4.75, which offer was refused and the strike resulted. Through the impairment of machinery, operations at the mines have been hampered. James Stratton, of Washington, D. C., an executive officer of the International Association of Machinists, was called to Butte to bring about a settlement. He had a conference with some of the mine managers and received from them an offer to pay the men \$4.75 per day and waive a time contract, which had been demanded for the machinists in the first place. The proposition was submitted to the machinists at a special meeting and was turned down by an almost unanimous vote. The following night the matter came before them at a regular meeting and was again rejected. "I think this is a good time to shut down all the mines," commented one of the big mine managers after the result of the vote was conveyed to him. That is what the mining and business interests fear will happen. It was expected that Stratton had authority to order the men to return to work if he found that their demands were unreasonable, but the machinists say he has no such authority.

The Gagnon mine, of the Trenton Co., which was compelled to close because of the machinists' strike, has resumed operations. The suspension has been made necessary by a break-down of the air-compressor at the Original mine, from which the Gagnon received its supply of air. The Gagnon has a small compressor of its own, which had not been in use, but it was pressed into service again and work in the mine resumed. The Gagnon, like all other mines of the Amalgamated Co., has reduced its ore output, little more than half the usual quantity being mined.

Operations at the Bullwhacker mine have been entirely suspended, pending the results of an experimental leaching test near Spokane. Several carloads of Bullwhacker ore have been shipped to Spokane to be tested, and if the result is satisfactory a leaching plant will be erected at the mine. The company claims there are 400,000 tons of oxidized ore in the mine above the 200-ft. level ready to be taken out. The Snowstorm Mining Co. near Mullan, Idaho, is operating one of these leaching plants with great success, being able to make a good profit with the price of copper between 15 and 18c. The Snowstorm ore runs much higher in copper than that of the Bullwhacker, the average assay of the latter being about 4%. —A strike of good ore has been made in the property of the New Boston Co., adjoining the property of the Boston & Corbin Co. The vein is reported to be six feet wide, 16 in. of which assays 10.6% copper, 42 oz. silver, and \$1.60 in gold. Three feet of the remainder of the vein assays 2% copper, 6 to 7 oz. silver. The strike was made at a depth of 150 ft. in the shaft. The New Boston is a Butte organization. The shaft is being sunk on the Daphne, one of the old claims of the Corbin district. The Corbin Wickes Copper Co. has also cut a vein at a depth of 90 ft. The vein contains about a foot of

high-grade ore. A cross-cut is 30 ft. into the vein but outside of the foot of ore the vein is only well mineralized at that depth.

The North Butte Extension Co. has completed its new surface equipment and it is working satisfactorily. The shaft is now down 200 ft. and Manager Ryan expects to make a record for sinking during September, if there are no accidents. He feels confident that at a depth of 500 ft. good orebodies will be opened. A cross-cut will be run at that depth. The indications have been good from the surface, and it is the general belief that some of the rich veins of the hill strike through the North Butte Extension ground. The company is well prepared to handle any amount of water, and no trouble is anticipated from that source.

As a result of the refusal of the smelters and ore-buyers to take any large amount of ore from the small companies and independent operators in the Butte district, many of the small mines have been compelled to close, while the output from other mines is restricted. Among the companies thus affected are the La France, East Butte Extension, Bullwhacker, Farrel, Alliance, and lessees in the Ophir, Amazon-Butte, East Butte, and several other mines. With copper at 20c. the small companies and lessees could sell their ore to the smelters and make a good profit, but at 18c. they cannot do it, even were the smelters willing to take the ore, which they are not. The Alliance had been making a good profit from shipments of from two to four cars per week, from which the company had been paying running expenses and development work. The ore being comparatively low-grade, it has been decided by the management not to raise any more until either the price of copper advances or the company has funds with which to build a concentrator. The Farrel Co., which is using the Alliance shaft during the work of cross-cutting on the 200-ft. level, has also been compelled to cease work, because of the shut-down of the Alliance. The officers of both companies are confident of the value of their ground, as it has been demonstrated that good orebodies exist on the 200 and 300-ft. levels, and they believe that before many months they will produce ore of commercial value. Thus far the stringency in the money market, the fall in the price of copper stocks, and in the metal itself have had no effect on many of the new development and exploration companies working in the Butte district. Satisfactory progress is being made by the East Butte, Amazon-Butte, Butte & Bacorn, Butte Central & Boston, Butte & Balaklava, Butte & Superior, Butte-Milwaukee, and British Butte companies.

The station at the 2,800-ft. level of the High Ore mine is nearly completed and cross-cutting at that depth will begin as soon as the pumping machinery is installed. With the opening of the orebodies at the 2,800, the Anaconda Co. will have 400 ft. of stoping ground in the High Ore, as no other cross-cutting has been done below the 2,400-ft. level. The object in going to the 2,800-ft. point without cross-cutting at the 2,600 is to drain the ground of the High Ore as well as handle the water from adjoining mines.—The Parrot Co. has begun mining in the Little Mina, and after a shut-down of that property for seven years it is again productive. The ore from the Clear Grit mine is also being raised through the Little Mina. Heretofore it has been hoisted through the Mountain Consolidated shaft. The Little Mina is expected to contribute materially to the production of the Parrot Co., for it contains a good vein of copper ore. The shaft is 1,000 ft. deep, having been sunk 200 ft. during the past few months. The shaft on the Parrot is also being sunk deeper, and is now down about 1,980 ft. At the 2,000 a station will be cut and cross-cuts started to

the veins. From the upper workings the mine yields about 300 tons of ore per day, and the veins at the 2,000 are expected to add materially to the output.

Joplin, Missouri.

Lower Prices for Zinc and Lead Ore. — Steps Taken to Curtail Output. — Statistics.—The American Mining Congress.

The highest price paid for zinc ore last week was \$46 per ton, and for lead ore \$62 per ton. The top price paid for zinc the first week of the month of August was \$50 per ton, and the assay base price was \$44 to \$47.50; the top price has declined \$1 each week, and the assay base has dropped to \$40. This price prevents many of the big sheet-ground mines in the Webb City district from running, at least they cannot make any money, and some cannot meet expenses. Last year at this time, as is nearly always the case, the price was down, but the price of lead was about \$20 per ton higher than at the present

the best remedy at hand to stay the downward market. It will work a hardship on the working-men and impair business to some extent, but in the end it is the only thing to do. There are agents here now from the West shipping men to Colorado and Idaho, and it is claimed 300 have gone thither since Saturday night. This will be hard on the mines here when they are ready to start again, as it will take some little time for all those that shut down to get a complete complement of men, but on the other hand a light production should help the market for ore.

The committee having in charge preparations for the American Mining Congress will meet in the Commercial Club rooms in this city on September 6 to outline plans for carrying on the work that is necessary before the big meeting. James F. Callbreath, Secretary of the Congress, will arrive here from Denver, and Dr. Buckley, the State Geologist, will also be in attendance. Secretary Gregory of the committee is receiving letters daily

from all over the country asking for the reservation of rooms at the new Connor hotel, which is to be completed in time for the Congress. Los Angeles will be well represented by a committee from their Board of Trade, who will make a strong effort to get the Congress in that city in 1908. For the first time in its history the Missouri-Kansas mining district is to have a mining exchange. The organization was perfected last night at the rooms of the Joplin Commercial Club.

Toronto, Canada.

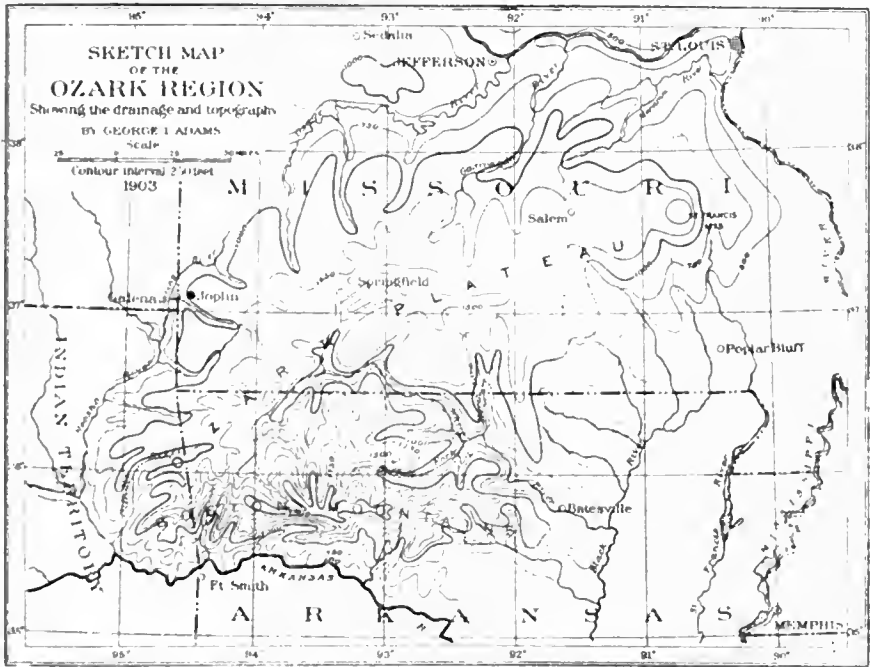

Government Profits From Mining.—An Important Suit.—Finds on Michipicoten Island.—Shipments From Cobalt.—Abitibi and Larder Lakes.—Another Goldfield.

The receipts of the Provincial Government of Ontario from the Cobalt mines so far amount to

\$1,467,850, made up as follows: Sale of Cobalt Lake property, \$1,085,000; sale of Kerr Lake property, \$178,500; royalties from O'Brien mine, \$170,852; royalties from Cobalt Townsite, \$3,189; royalties from Right-of-Way, \$30,309. This is in addition to receipts in the ordinary way from the sales of mining land.

Another attack has been made on the title of the Cobalt Lake Mining Co., which was confirmed last April by a special act of the Legislature. This legislation is still liable to be set aside by the Dominion Government as *ultra vires*, the action brought by the Florence Mining Co. who claim the property on the ground of prior discovery being in the meantime suspended. The present suit is brought by James J. McConvey who asks for an account of all dealings by the directors with respect to the assets; the cancellation of all stocks not paid for at par; for damages for improperly procuring the passage of the act guaranteeing the company's title "which by implying the invalidity of the title to the property of the said company and the validity of the adverse claims thereby depreciated the value of the shares;" and for damages for wrongfully issuing shares at a discount. The Court is asked to appoint a receiver.

There is some excitement over discoveries of native copper and silver on Michipicoten island in Lake Superior some 15 miles from Sault Ste. Marie. Gordon Mi-

Map Showing Position of the Joplin District.

time, and as the sheet-ground is rich in lead, these mines were able to make a little money, but with zinc and lead both down it is a different matter entirely. The stock in the bins has averaged from 5,500 to 7,000 tons for the past four months, a condition that is in itself a menace to ore prices. A restriction of the output during July would have been, seemingly, a proper thing, and would have prevented at least half the loss the district has sustained. This loss, by lower prices, now aggregates over half a million dollars.

Shipments.	Zinc, lb.	Lead, lb.	Combined value.
Week of August 31.....	9,307,330	2,314,010	8 281,657

A large number of the big producers met at the Newland hotel in Webb City, on August 30, for the purpose of devising some plan to stop the downward tendency of the ore market, and it was agreed that the proper thing to do was to shut down the mines for four weeks. The producers present represented about 3,000 tons output per week. A committee was appointed to make a canvass of the entire district and procure the name of every producer to aid in the shutdown movement, in order to make it general. The decrease of production seems to be

chael, of Sault Ste. Marie, has been prospecting there since the spring and has recorded a number of claims. He brings samples showing native silver attached to native copper. H. C. Wilnot, who has examined the samples, says that the specimens of silver are as good as any that have come from the Montreal River district. Michipicoten island, he states, is geologically like the Keweenaw peninsula, and there is good reason to believe that native copper deposits, similar to those at Calumet, may be found there.

Shipments of Cobalt ore for the week ending August 31 amounted to 225 tons, from the following companies: Buffalo, 50 tons; Coniagas, 80; Kerr Lake, or Jacobs, 30; Nipissing, 32; Tretheway, 32 tons of ore.

At the Foster mine a mineral rich in silver and supposed to be argentite, which occurs in small quantities from the surface to the 50-ft. level, has been identified as stromeyerite. In contact with it has been found a new mineral known as gyropyrite, an amalgam of the sulphides of silver and iron. The Rothschild mine has been shut down for some time, work being unprofitable, but in prospecting a new vein has been struck containing some silver nuggets, and this may cause work to be resumed. The Colonial mine, which has been closed down since the strike began, has been re-opened and three drills are running. At the Right of Way the new shaft is down 57 ft. and will be continued 50 ft. farther, with a cross-cut at 75 ft. to the vein.—The new plant of the Rochester is in operation. The main shaft is down 80 ft. and ore is being taken out running from 2,000 to 3,000 oz. of silver per ton.—A new calcite vein with good silver contents, has been found running parallel to the main vein.—Work is being rapidly pushed at the Hazel-Jule property on Sasaginaga lake. Trenching to the extent of 1,500 ft. has been done and seven good veins found, one being about 20 in. wide with a good showing of silver. D. M. Gilpin is superintendent.—At the Edison mine, which has been worked for cobalt, a vein about 10 in. wide with good silver contents has been found at 150-ft. depth.—The main shaft of the United States mine is down 45 ft. on a wide silver-bearing calcite vein. Assays have shown 2,900 oz. silver per ton.

Last winter several gold claims were staked by Dan Mosher on islands in Abitibi lake. The La Rose interests secured an option and have been operating two steam-plants in developing the property. They have sunk one shaft 76 ft. on a vein 30 in. wide and are driving at that level. It is reported that a deal is practically arranged.—Development at Larder lake has been greatly retarded by delays in the delivery of plants ordered. At the Blue Bell a shaft is down 40 ft. and driving is being done. Free gold has been found on some of the properties owned by the Tighe syndicate.—At the Chesterville location on Northeast bay, a rich vein has been struck varying in width from 4 to 5 ft., which has been traced for 400 ft.—On the property of the Lincoln Nipissing Co. on the Southwest bay, a reef 200 ft. wide has been traced 900 ft., and free gold is visible in many places. A plant has been ordered.

Night Hawk lake is at present the magnet of attraction for prospectors, who continue flocking to the new gold-field. Many locations have been taken up since the first discoveries were announced. Night Hawk lake is situated nearly due west of McDougall's Chute, which is 100 miles north of Cobalt on the Temiskaming & Northern Ontario Railway. From McDougall's Chute it is reached by a circuitous canoe route with numerous portages. The formation is described as soft diorite and chloritic schist. The discoveries were made on islands in the Northeast bay of the lake, and as development progresses free gold of the size of peas is being found.

J. A. Herman, who was the first mine superintendent of the Nipissing, has staked several locations, and a Detroit syndicate is developing several claims with encouraging results.

Cripple Creek, Colorado.

Strike on Gold Hill.—The Drainage Adit.—Rapid Progress.—Ironclad Clean-Up.—The Masterpiece Mines.—Base Ores From the Ben Hur.—Stratton's Independence Mill.

A rich strike is reported on the south end of the Mattie L. claim of the Mattie L. G. M. Co. on Gold hill. A shaft was started 22 ft. from the east line of the Anchoria-Leland property and at a depth of 6 ft. ore was opened in a porphyry formation. Assays giving over \$300 per ton were obtained from the vein, which is 18 in. wide and shows sylvanite in many places. The orebody is believed to be at the junction of two new veins. Good ore has at times been obtained from the north end of the property, but the grade was not up to that of the present strike. Peterson and Jones are sub-leasing from Ed. McKenzie, who has a bond and lease on this property.

The original dimensions of 8 by 10 ft. for the drainage adit will be adhered to. The rapid progress made by the El Paso Consolidated Gold M. Co. has led the committee, appointed to look into this matter, to re-consider the decision accepting bids for dimensions of 5 by 8 ft. The rock seems to be softer than for the first 300 ft., making progress more rapid than before, and when the water-course is tapped still greater advancement is expected. At the present rate 8,500 ft. of advancement can be done within a year.—As a result of operations in the drainage adit activity on properties on the line of the bore is evident. On Cowan mountain a contract to drive the Peabody tunnel 200 ft. from the present heading has been let to Thier & Hull. The heading is already 1,200 ft. from the portal. Other properties in this neighborhood are undergoing development.

After a two-weeks run by the Ironclad M. & M. Co. a clean-up has been made which gives a gold retort of the value of \$3,016. The mill treated 1,050 tons of ore of an average value of \$2.85. Semi-monthly clean-ups are made at this mill, producing substantial profits.—Another mill for Ironclad hill is reported to be under consideration. Charles M. Kurie of Colorado Springs is said to be drawing up the plans for a 50-ton cyanide plant to be erected on the Pessimist property.—The new mill of the W. P. H. is expected to be in operation within a week if material, which is on the way, is not delayed. Ore is now being hoisted from the shaft of the W. P. H. Extension Co., situated at the west end of the property for treatment by the mill, which will have a capacity of 100 tons.—The Wishbone mill on the north side of Carbonate hill has entered the market for custom ores. It is the only cyanide mill in the district that crushes by means of stamps, of which there are 20, giving a capacity of 100 tons per day. There is a great deal of low-grade ore on the Sunshine, Black Diamond, and other properties adjoining, which can be milled at a profit.

The Masterpiece Gold Mines Co. is preparing to install a six-drill compressor at the Masterpiece tunnel on the eastern slope of Bull hill. This adit is 300 ft. long at the present time, and was driven to cut several veins that had been encountered in shallow shafts. The company is also preparing plans for a 50-ton cyanide mill. The property comprises 53 acres of patented ground, development of which has opened up large bodies of both smelting and milling ore. With the installation of the compressor, the property is expected to become a regular shipper. Lessees Richard Blanchard and C. B. Eaton,

operating the Little King claim of the Ben Hur property, on Gold hill, recently made a shipment of particular interest, as the ore shipped was different from that characteristic of the Cripple Creek district. This shipment, in addition to gold, contained silver, lead, and zinc. The ore was extracted from a space 30 by 18 ft. and about 200 ft. below the surface. Assays from the orebody were particularly good and returns from the shipment netted a substantial profit. It was the intention of the lessees to erect a 50-ton cyanide plant at the portal of the Good Will tunnel, but, owing to the improved conditions, it is announced that \$50,000 will be expended in the erection of a 200-ton plant. The lease has 15 months to run. Many pockets of high-grade ore have been encountered on Gold hill, but this one seems to be the most important in years.

The work on the Stratton's Independence mill is well ahead of the scheduled time. Enforcement of the card system and the Labor day celebration caused a scarcity of men for a short while, but a full crew is now at work again. Should the favorable weather of the past month continue, the superstructure of the mill will be practically in place by the end of September, and if machinery arrives promptly the work will be finished in advance of the time allotted for the construction of the first unit of the plant.

Vancouver, British Columbia.

The Fuel Problem in the Boundary District.—Scarcity of Coke.—Smelting Operations Crippled.—Action by Board of Trade.—A Comparison With Arizona.

The mining and smelting interests of British Columbia are making a vigorous attempt to solve the fuel problem that has confronted them for some time. It has been impossible to get a substantial stock of coke on hand at any of the smelters, and the operation of the plants has necessarily been irregular as they were dependent upon daily shipments of fuel to carry them along. One after another, they have been forced to close down for periods of time varying from a day or two, to several weeks. These irregularities have made mining operations equally uncertain, with the result that men have to be laid off, or changed from stoping to development work at short notice.

Recently, the matter has been called to the attention of Premier McBride, who promptly sent a deputy to the Kootenays to look into the situation. This deputy has visited Trail, Nelson, Kaslo, and Fernie, and is soon to report conditions as he found them. In view of the bad effect that this insufficient supply of fuel is having upon the mining industry throughout British Columbia, it seems unjust to the operators that coke should be exported to the smelters in Montana; they maintain that only the surplus above local needs should be sold across the line, whereas the records of the customs department show that up to August, the exports to the United States for this year have already been in excess of 27,000 tons of coke. It is estimated that this amount of fuel would have made it possible for the Trail and Boundary smelters to treat a quarter of a million tons of ore more than they did. The Nelson Board of Trade has adopted resolutions calling upon Premier McBride to stop the sale of coke by the Crow's Nest Pass Coal Co. to alien companies. The Rossland Board of Trade has followed, with a set of resolutions regarding this "serious menace to the mining industry," condemning the sale of coke to outside companies and the inadequate transportation facilities furnished by the railways, demanding that the Provincial Government take action in the matter, and suggesting the throwing open of 50,000 acres of Government coal

lands, preferably as a Government-operated coal mine. The Trail Board of Trade has just passed a resolution, asking that the provisions of the charter be enforced.

Another cause of the trouble seems to be the shortage of men at the collieries and coke-ovens, due to the fact that wages have risen in the metal mines, harvest fields, and lumber camps, until they are higher than those paid for this class of labor at Crow's Nest Pass.

Anyway, the people of Rossland and Boundary districts seem to be going about the correction of the shortage in a businesslike and energetic way, and backed in their demands by an independent press and the Provincial government, a speedy adjustment is hoped for. The Crow's Nest Pass Coal Co. has openly violated the terms of its charter, which provide that if a supply of coal and coke for Yale and Kootenay counties is not forthcoming in sufficient quantities for the smelters and refueries, the company shall pay a penalty of \$2 per ton in respect to the shortage.

The successful exploitation of the copper ores of southern British Columbia is known to depend upon production on a large scale. The tendency evinced by all the producers is to enlarge their smelting plants. The Dominion Copper Co. is already equipped to handle

Map of Part of British Columbia.

1,200 tons of ore per day; the Consolidated company, 2,000 tons; the Granby company, 3,000; and the British Columbia Copper Co., 1,200 tons per day. This combined capacity of 7,400 tons per day is sure to be doubled within the next five years if the industry is given a chance to expand. But before any such enlargements are justified, an adequate supply of fuel must be assured, and the successful settlement of the present trouble is vital to the future of mining in the region. Some of the plants receive coke from the Alberta ovens, but the Granby smelter at Grand Forks and the Consolidated plant at Trail, the two largest smelters in Canada, are dependent upon the Crow's Nest Pass company for their supply.

In contrast to the hand-to-mouth method of supplying these smelters with coke, comes the news of the washout of portions of the Gila Valley, Globe & Northern Railway in Arizona, over which is hauled the supply of coke for the Old Dominion smelter at Globe. Although all traffic may be suspended for weeks, and even the wires are

down, there is no cessation in the operation of the plant, as a supply of fuel is on hand sufficient for a protracted run. If the Canadian smelters could be assured of a regular supply and could carry a comfortable surplus of fuel on hand, the whole southern portion of British Columbia would benefit greatly thereby.

Salt Lake, Utah.

Operations at Bingham.—Boston Con. Mill.—Strike in the Standard.—

Consolidation of Mines at Park City.—Ore Shipments.—Ontario

Adit.—Eureka Railway.—Dividends.—Shipments From Tintic.

The Bingham-New Haven Mining Co. is about ready to operate its Bingham mine through the lower adit; but before doing so, it will be necessary to shorten the aerial tramway about 2,000 ft. At present the upper terminal is at the portal of the upper adit. Under the new arrangement the property can be worked more economically than heretofore and it will not be compulsory for the

Utah.

company to maintain a boarding-house.—The building of the aerial tramway over which the ores of the Yampa mine are to be conveyed to the smelter is progressing satisfactorily. It is expected that the system will be ready for operation in October.

The first section of the Boston Consolidated Mining Co.'s new concentrating mill will be ready within the next 30 or 40 days, and it is expected that the five sections of the initial unit will be in operation by the end of the year. This, of course, is contingent upon the Rio Grande Western supplying the required tonnage of ore—2,500 tons daily—from the company's mines at Bingham.

Lessees working in the Bingham Standard mine have opened a body of high-grade lead ore in the Saginaw tunnel, and shipments are being made to the Salt Lake smelters. The Bingham Standard company has cleared up the options on some of its possessions preparatory to transferring the assets of the corporation to the Bingham Central-Standard Copper Co., which organization is a result of the merger of the two mines. The stock of the old corporations is being transferred to that of the new one. Arrangements have been made with

the management of the Nevada Utah Mines & Smelters Co. for the use of the Last Chance mill at Bingham for the treatment of low-grade ore.

The merger of the Creole mine at Park City with the Uintah Treasure Hill has been concluded, the directors of the former agreeing to accept the same amount of stock in the Treasure Hill Consolidated Co. as they now hold, subject, however, to ratification by their shareholders.

The Uintah Treasure Hill Co. is now in possession of over 20 lode-mining claims which are situated between the town of Park City and the Woodside mine of the Silver King Coalition. It is claimed too that the Treasure Hill ground contains a continuation of the contact vein from which the Silver King has obtained a large portion of its riches.—The ore shipments from the mines of Park City during August amounted to about 10,000 tons, the contributing mines and respective amounts being: Silver King Coalition, 3,441 tons; Daly West, 3,739 tons; Daly Judge, 1,742 tons; American Flag, 396 tons; Little Bell, 246 tons; Copper Apex, 45 tons; other mines, 120 tons.

The work of re-opening the Ontario drainage adit is progressing tediously. Some time ago the management tried the experiment of using pumps to unwater the mine, but the plan has not proved an entire success. A drift is being run around the latest obstruction in the adit, and by the use of diamond-drills run ahead of the breast the men employed in that particular portion of the property are proceeding with their labors in comparative safety. The adit has been out of service for about two and a half years.—The grading of the Eureka railway, the new line to be operated in connection with the operation of the smelter of the Tintic Smelting Co.—now under construction—has been practically completed. The ties and much of the rolling stock has arrived, and the management has been advised that the steel rails have been shipped. The construction of the smelter is going along nicely and it is expected that both the railroad and the smelter will be ready by the end of the year.

The splendid results achieved through the development of the eastern portion of the Tintic district has caused mining men to look to the northern portion of the camp, where little systematic development has been done heretofore. Several new companies have been organized recently with strong financial backing. Engineers who have examined this part of Tintic recently are confident that money spent there in development will be productive of good returns.—The directors of the Uncle Sam Consolidated Mining Co. have posted a dividend of 3 cents per share, or \$15,000, payable this month.

The Daly West quarterly dividend of 60c. per share, or \$108,000, has also been posted for payment on the 15th inst.—The annual election of the City Rocks Mining Co., with properties at Alta, has been held and has resulted in the selection of W. S. Cleaves of Hancock, Mich., as president; John Edwards, Houghton, Mich., vice president; James P. Edwards of Houghton, Mich., secretary and treasurer; W. S. Zehring of Salt Lake, assistant secretary and manager.—Ore shipments from the Tintic district last week amounted to 140 carloads, the contributions coming from 22 mines, the mines and respective amounts being: Ajax, 4; Beck Tunnel, 8; Bullock, 1; Bullion Beck, 9; Carisa, 2; Cliff, 1; Colorado, 8; Centennial Eureka, 44; Eagle & Blue Bell, 9; Eureka Hill, 3; Grand Central, 6; Gemini, 5; Godiva, 2; Laclede, 5; Mammoth, 10; May Day, 5; Scranton, 8; Swansea, 1; United Sunbeam, 1; Uncle Sam Con., 4; Yankee Consolidated, 2 carloads.

Denver, Colorado.

The Card System.—Drainage Adit at Cripple Creek.—Ore Reduction at Lake City.—A Zinc Plant.—Local Politics.

The recent abandonment of the card system at Telluride has produced a not unexpected effect on the labor situation at Cripple Creek. At the same time that the bars were being let down at Telluride they were being put up at Cripple Creek; all the men in the camp were given until September 1 to take out new cards, no man without a card to be employed after that date. As a result several men have gone out, but as the labor market at Cripple Creek, in strong contrast to all the other camps of the State, is not short-handed, there is no reason to expect that there will be any trouble. A few timbermen at the Portland have gone out, demanding an increase of wage from \$3.50 to \$4, but as the Portland mill is now handling a certain proportion of Golden Cycle ore, according to their agreement, this will not even create any irregularity until the striking men can be replaced. For the first time in many years the monthly production of the district for the month past has fallen below a million dollars; this is due, of course, to the curtailing of the output of low-grade ore which was being shipped to the Golden Cycle mill. The U. S. Reduction & Refining Co. has reopened its mill at Florence, and has also rescinded the penalty previously placed on sulphide ore, as compared with the oxidized. This practically amounts to a lowering of treatment charges, and next month will probably show an increase in the production.

The driving of the deep drainage adit is now being carried on by the El Paso Mining Co., that company having taken the contract at a somewhat higher figure than the first contract. The adit has been advanced 540 ft. and is being driven at the rate of about 8 ft. per day. The sinking of the intermediate shaft is also progressing satisfactorily. A disagreement recently arose in the directorate of the El Paso company, one of the directors being dissatisfied with the way in which affairs were being managed, especially with respect to the tunnel contract. The recent meeting went off smoothly, however, the disgruntled member confining himself to threats of vengeance.

The Hidden Treasure mine at Lake City, which has produced valuable ore, but which has been idle for some little time, is expected to re-enter the rank of the producers as soon as the changes in the mill can be completed, \$50,000 being expended for that purpose. Most of the ore of Lake City offers a difficult problem for treatment. It is not high enough in grade to ship direct, or else it is prohibitively high in zinc. The local smelters have not been able to operate successfully, not being able to secure the variety of ores necessary to make an easy fluxing mixture. In addition, the district is remote from any adequate fuel-supply. To mill most of the ore is quite impossible, as the value lies chiefly in the silver contained in an argentiferous tetrahedrite, which slimes so badly that a prohibitive percentage is lost in the tailing. Even the extensive use of canvas tables and blankets fails to remedy this difficulty, although a decided advantage. Lately ore is being opened up on the borders of the district that is more amenable to treatment, and several good producers may result from this development.

The trial of the promoters of the Lost Bullion Spanish mines has finally been concluded, resulting in the conviction of all the defendants, although the penalties imposed are somewhat unequal. It was a case of particularly bare-faced swindle, and it is to be hoped that all similar promotions may receive similar treatment

from the Federal authorities. The States are helping in this movement, and Connecticut has recently been added to the list of those that have laws to protect the innocent investor from dishonest promoters.

The company which is to build a smelting plant at Canyon City to treat its own and other ores by the Lewis & Bartlett process, announces that it has secured a lease for 99 years on a site about a mile south of the Empire zinc plant, and that a satisfactory contract for the necessary coal supply has been concluded. The promoters have secured the services of a man experienced in the operation of the process, and expect to proceed immediately with construction work. Their entry into the ore market will be a decided benefit to the smaller mines

A Part of Colorado.

whose lead ores are too high in zinc to be acceptable to the smelters, and whose properties are not large enough to justify the erection of a mill.

With the coming of the autumn days the political situation again begins to assume interest. The recent speech of Secretary Taft in Denver was enthusiastically received by a large crowd, for it was marked by a breadth of insight, a calmness of judgment, and a fairness of spirit that could only appeal most favorably to the people of the State. The Secretary appealed equally favorably to the party leaders and is said to have brought harmony to the dissident factions. It would take more than even Mr. Taft's abilities to bring about a reconciliation between Gov. Buchtel and Judge Lindsay, however. These two belligerents have both returned to Denver from their Eastern trips, and the public will doubtless soon have opportunity to enjoy more spectacular use of language. Whatever the effect of Judge Lindsay's statements may have been, the Governor has probably sacrificed himself politically by his attitude in regard to the commandant of the Soldiers' Home, and by what are reported to be his statements in regard to the members of the Grand Army. Still, it is probable that the reverend Governor has served his purpose politically, and would have been retired at the end of his term in any case. Certainly, he will be retired. Just how Mr. Thomas F. Walsh will secure his own election to the United States Senate is also a matter for interested conjecture.

this grouand is diping to fast in to the sutheran gouter to doe much with till the water as been taking of the sutheran leade. the Bore as duane no father with the Bore it stands at 350 i have to Bolers cleand i stoped them on wire from doane the remane to. i May state that this groun turn out Better thean i expted can to the goald Being threw the wash. While the orthography of the above epistle will appeal to you to about the same extent that its immodesty will to Mr. Herzig, I am not without hope that, failing President Roosevelt, some keen advocate of phonetic spelling will signify his approbation.

All of which does not hinder me from expressing my sympathy, Mr. Editor, with your endeavor to induce more care in technical writing.

W. J. LORING.

Melbourne, August 1.

Weathered Pyrite.

The Editor:

Sir—I address myself to your valuable paper in the hope that the herein following query may attract the attention of one of our authorities on mineralogy.

To what can be attributed the fact that the croppings of bodies of iron sulphides in the desert region of California consist generally of hematite and magnetite; while in northern California they consist generally of limonite, carrying only occasionally hematite and magnetite, and then only in granular form?

Is it possible or probable that in the desert region these croppings were originally limonite, which was dehydrated by the existing climatic conditions? Or may the reason be that these iron sulphides were deposited by the mingling of solutions carrying metallic sulphates with solutions carrying salts of sodium, potassium, calcium, *et cetera*.

Bearing on this point, it may be noted that considerable calcitic material is associated with some of the anhydrous croppings in the desert region, and that the only anhydrous croppings observed by me in Shasta county are contiguous to the great body of Carboniferous limestone on the McCloud river.

WM. FORSTNER.

San Francisco, August 7.

Conveying Tailing in Launder.

The Editor:

Sir—I have read with much interest the description appearing in your issue of June 29, on conveying tailing in cast-iron pipe at Guanajuato, also the further statements on the same subject by Mr. Van Law in the issue of July 20. Having in the last two years made about 7,000 experiments on the carrying capacity of launders, the subject is of course interesting to me. In my experiments on tailings which were clean pure quartz and quartzite (probably much more angular and sharp than the material at Guanajuato) I find that on a grade of 1.5% in a rectangular launder on material of the fineness mentioned in your article one pound of water will only carry off 0.022 lb. quartz, when the launder has the most economical width for the quantity of material carried.

My experiments also show that with the most economical width of launder, the same material with water in the proportion of 7½ to 1 would require a grade of nearly 5%. Only on absolute slime did I obtain better results

in a V-shaped launder than in a rectangular one. My experiments were checked, some twice and some three times.

Why my results are so much lower than those mentioned, I would like to ascertain. I know Mr. Van Law personally and know the figures he has given can be nothing but correct, and the difference must be wholly in the nature of the two materials handled (this refers to the issue of June 29).

With your permission, and begging the pardon of my brother engineers, I can positively state that the "wetted perimeter" has nothing whatsoever to do with the carrying capacity (as far as solids go) of a launder. Personally, I was formerly under the impression that it had, but my experiments have conclusively proved that we have all been wrong in this assumption. For example, a 1-in. launder using 25 lb. water per min. will carry exactly one-half of the tailing of a 2-in. launder using 50 lb. water, and one-tenth of a 10-in. launder using 250 lb. water per min., all, of course, on the same grade; that is, the carrying capacity in sand, etc., is proportional to the width. This I can prove by figures from about 500 actual experiments. In the next statement I shall probably get myself into trouble, but Mr. Van Law's experience will bear me out.

Under the right conditions, material can be transported in a pipe. On a grade, we could not possibly transport it in an open launder, but the initial grade should be greater than the grade at the end (the sooner to develop pressure) which in an open launder would be bad practice. But, as a rule, we can only utilize a pipe on very fine material, and when handling comparatively large quantities. To make myself clear, if we attempt to transport in a pipe ½-in. material at the rate of 10 lb. per min. on a certain grade, with the least quantity of water, the theoretical size of pipe required would be so small that in a short time the pipe would clog, but to transport 100-mesh material through the same pipe would be easy. I know full well that pipes used in mills in place of launders, often give much trouble and it is not my purpose to recommend pipe in place of launders, except for carrying off great quantities of comparatively fine tailing. There is more to Mr. Van Law's expression, which I will quote, than most of us (probably even himself included) would think. "As soon as riffles of sand are formed so as to cause an obstruction in the flow, the pipe develops hydrostatic head above the point of obstruction sufficient to force the sand through." That is, if the pipe is too large to give the velocity of water that will keep the material in suspension (or carry it on the grade used) then nature itself, by the filling in of sand, reduces the size of the pipe down to the point where the velocity will be high enough to carry the material off, depositing it ahead again where velocity is slower, until this point in turn reaches the carrying stage, and so on. This action also shows to some extent in a launder, but the effect is not the same as in a pipe, because the launder can keep on filling up and water still flows on top, without increasing its velocity at that point. The carrying of tailing in a pipe and in a launder are two entirely different problems, and do not at all follow the same laws. In the pipe we depend mostly on the head developed, but in the launder on the rolling and sliding action down an inclined plane, except in the case of exceedingly fine material, where the hydraulic condition or wetted perimeter approximates the right proportion of a launder. I hope in another year to finish my investigation in regard to the problem of launder capacity and to present it in much better form than these ramblings.

G. A. OVERSTROM.

Salt Lake City, August 31.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

The Royal School of Mines.

The Editor:

Sir—In your issue of July 27, there is a letter from Mr. F. Lynwood Garrison, which is evidently based on imperfect knowledge of the facts connected with the incorporation of the Royal School of Mines with the new Imperial College of Technology, and as Mr. Garrison evidently writes with sympathy for the old R.S.M., he will, I am sure, be pleased to have some of his impressions corrected.

In the first place, Mr. Garrison has expressed surprise at the absence of protest by old School of Mines men against the change, and he has at the same time, poured ridicule on the whole scheme of the new Imperial College. If there is one thing clearly established, it is the intense interest which old School of Mines men have taken in the idea of an improvement of the School, to keep it up to date, and in the consideration of the proposed amalgamation with a general college of engineering, or rather technology. This interest has taken effect by means of the council of the Institution of Mining & Metallurgy, on which are a number of School of Mines men, including the present professors of mining and metallurgy of the R.S.M. The effective work of the Council is on record in its publications for the last four years, and it is well known that the Institution has exerted a very great influence in the appointment of a committee by the Board of Education, to examine into the present condition of the Royal School of Mines and the Royal College of Science, with which it is incorporated, and to advise as to means for improving their efficiency. In the submission of evidence to this committee, the Institution took an active part, and was represented on the committee. The recommendations of the committee (which have practically been completely carried out in the formation of the new Imperial College of Technology, with the preservation of the identity, the title, and the diploma of the Royal School of Mines) were fully agreed to by the council of the Institution, which is equivalent to saying that they were agreed to by the great majority of R.S.M. men, past and present students, who had taken sufficient interest in the matter to express opinions and offer services.

It is quite true that a majority of R.S.M. men would have preferred to see the School stand as an independent Government institution, and handsomely endowed by the Government or by individuals, so that new buildings, testing works, and reasonable salaries to professors could be secured. Conditions in London, however, were entirely opposed to this. There are a number of other schools of mining and metallurgy now established in England, and it was perfectly evident that a British Government would no longer take the position which led to the original foundation of the R.S.M., in spite of the fact that the British Empire is now producing something like \$400,000,000 from mining, other than that of coal and iron. As regards individual donations, London suffers from the disadvantage of being a world, and not a provincial city; there is no feeling of provincial pride among dwellers in London, and generally in England, large donations for educational purposes are less frequent than in the United States, where also such donations are often local in character.* A notable exception in the

present case is the gift of an aggregate of about \$1,000,000 from the members of the firm of Wernher, Beit & Co., the wellknown mining house of London, which sum has come into the possession of the new Imperial College of Science & Technology, and will insure proper buildings, at last, for the Royal School of Mines.

The new college will have annual grant from the Government, which hands over the Royal School of Mines and Royal College of Science, and it will receive further annual grants from the London County Council, the City guilds, and other sources, and it will be in a position to co-ordinate the highest technological training as well as to correct the present overlapping and heterogeneous management of scientific education in London. The names of the board of governors of the new college will be evidence sufficient that not only are pure science and educational ability well represented, but that there is plenty of industrial engineering talent of an eminently practical character to insure proper regard to modern progress, while the R.S.M. is strongly represented, and the coal and iron mining interests are separately represented.

From the above, it will, I hope, be seen that on this side, neither mining engineers generally, nor R.S.M. men particularly, are of Mr. Garrison's opinion that the new Imperial College of Technology is a "humbug," nor that its organization has been the "work of a parcel of politicians."

WALTER McDERMOTT.

London, August 23.

[This letter from Mr. McDermott is most timely, for he has taken so useful a part in the work of the committee appointed by the Board of Education that anything he says will be read with interest. We are glad to learn that the R. S. M. men in London approve of the new scheme, and perhaps if we were living there our accord with the new departure would be complete. As it is, looking at the matter from a distance, it still seems to us queer that London, the great financial centre of mining operations, and England, the mistress of a world-wide mineral empire, should be able to do nothing better than tack a historic School, honored by some of the greatest men of science, to a College of Technology of a non-descript character. The only good feature is the independence of the new School of Mines from the Board of Education. For the rest, while the school has been saved—thanks to Mr. McDermott and the Institution of Mining & Metallurgy—it has not received the treatment warranted by the relation it bears to the mineral industry of the British Empire.—EDITOR.]

On Technical Writing.

The Editor:

Sir—As an interested follower of the controversy between yourself and Mr. C. S. Herzig, I crave permission to add to the bone of contention by bringing under notice a mine manager's report to his directors. The fact that this interesting curio was discovered among the official documents of a mining company now under my control, disposes of any doubt as to its authenticity. I quote the report *verbatim et literatim*:

"to the Drectors,
"geantlemen—i ham fored you plan and you will see by it the Mount of worke Duan in it the west Drive has dipped under foot and is making a good drope of water shoun it is goe fast in to the Sutheran leade it Dips 8 feet in 12 the wash a come down in the South Drive and with fare prospect After getting wire to stop i wash off to half Mechean for 6 oz 8 from sevean seets of drivean wich is very good i did not take up the Bottom of the Mechean if i had i wood have got over 7 oz i ham suare.

* In other large cities of Great Britain handsome donations for local educational institutions are not uncommon.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE Wilfley table was first used by A. R. Wilfley in his own mill at Kokomo, Colorado, in May, 1896.

SODIUM CYANIDE is equivalent to 124 to 128% active potassium cyanide, and is guaranteed to have a comparative efficiency of 125 per cent.

IN THE oxidized ore at El Oro, Mexico, the ratio of gold to silver is $6\frac{1}{2}$ grams of silver to 1 gram of gold; while in sulphide ore the proportion is as 15 to 1. This indicates the concentration of gold above water-level.

SHIPMENTS of Government tin from Java in 1906 amounted to 9,807 tons, as against 9,344 tons in 1905 and 11,749 tons in 1904, while the quantity of private tin shipped was 1,935 tons, as compared with 2,237 tons in 1905 and 3,077 tons in 1904.

THE hand jig is one of the cheapest and simplest washers, and can be put together with a few tools in isolated places; where labor is cheap, the cost per ton is low, and when the tonnage is low, the simplicity of the hand jig gives it preference over the more complicated and expensive power jiggling plants.

ANALCITE, a sodium aluminum silicate crystallizing usually in trapezohedrons, occurs with prehnite, datolite, and calcite, in the Lake Superior region; in the gangue of copper at Copper Falls; and at Michipicoton island. It is also found in New Jersey; in gneiss in New York; and in Maine, with apophyllite in greenstone.

IT is generally thought economical to build a mill or reduction plant near the mine, that is, within less than 500 ft., as getting the ore to the mill is an important factor. In the Lake Superior copper region, the mills are so large as to make it cheaper to haul the ore from the mine to the shore of the lake by railroad, even though the distance be from one to seven miles, because a cheap supply of fuel, ample water, and a dumping place for the tailing is thus gained.

THE CHIEF distinctions between pyroxene and amphibole are that the prismatic angle with pyroxene is 87° and 93° , and with amphibole 56° and 124° , while the prismatic cleavage is much more distinct in the latter. Pyroxene crystals are usually short prismatic and often complex in form, with a lamellar or granular structure of the massive kinds; while with amphibole, the crystals are chiefly long prismatic and simple, with columnar and fibrous massive kinds the rule. The specific gravity of most of the pyroxene varieties is higher than similar varieties of amphibole.

THERE may be some refined methods of 'spitting' fuses, but the commonest method in practice is to unwrap the tape for about two inches, then split the fuse exactly in two, preferably using a sharp knife with a thin blade and handling the end carefully in order that the powder may not be scattered. Then apply a candle, always having a lighted snuff near, as the flash may blow your candle out. When one fuse is going, if there are more within reach of it, they may be lighted by holding their ends to the burning one. In quarry or other outside work where the thing is feasible, a hot bar of iron makes a good lighter.

GYPSUM occurs in sedimentary rocks of practically all ages, either in the crystalline form or as rock gypsum, and it is widely distributed over the world. It is found

commonly in the vicinity of beds of rock salt. In the United States workable deposits are confined to beds of rock gypsum, which occur at comparatively few geological horizons. The gypsum beds east of Missouri river are, for the most part, in Paleozoic rocks, while those of the West are mostly of Mesozoic and Tertiary age. The white gypsum sands of Arizona and New Mexico are of fine-grained material that has been eroded from rock outcrops and worked by the winds into its present condition and position in Quaternary time.

THE lower-grade chromite ores are used as refractory basic linings for furnaces, both reverberatory and blast, and in the manufacture of chrome bricks for the same purpose. The Canadian ore is particularly adapted for furnace lining as the silica present in it is combined with magnesia. Strange to say the presence of a fairly large amount of silica was used as an argument against the Canadian ore when it first came on the market; but tests made by many steel companies in the United States show that this ore lasts nearly a third longer than foreign ores. The principal competitors of the Canadian ore have been the mines in New Caledonia in high-class ore and the Turkish and Russian mines in the low-class; but owing to their distance the Canadian mine owners have always been able to undersell them. If the progress of the past four years keeps up there is no reason to doubt that Canada will be able to dictate the price of chrome in the markets of the world.

THE GYPSUM mined in the United States in 1906 amounted to 1,540,585 short tons, valued at \$1,147,129. This production represents an increase in quantity of more than 47%, and in value of nearly 40%, as compared with that of 1905. This largely increased production, which surpasses by far that of any previous year, is accounted for partly by the rapid increase in new producers, the total number of whom at the close of 1906 amounted to 74, as against 46 in 1905, a gain of 61%. Since few of these, however, operated the whole year, they cannot be credited with a proportionate share of the increase in production. As to relative rank among the States producing gypsum, Michigan still holds first place. New York regains second place, with Iowa a close third. The remaining States show few changes in relative position since 1905, their present rank being as follows: Texas, Ohio, Oklahoma, Kansas, California, Wyoming, Virginia, Nevada, Oregon, Utah, New Mexico, Colorado, South Dakota, Alaska, Montana.

FELDSPAR may be altered through infiltrating waters carrying more or less carbonic acid in solution; also through the action of waters rendered acid by the decomposition of sulphides; or by ordinary waters holding traces of alkaline and other ingredients in solution. The presence of iron sulphide or a mineral containing iron protoxide, as some mica, garnet, etc., is often the first occasion of the change. The decomposition of the mineral, with the attendant oxidation of the iron, distributes ferruginous waters through the rock, and thus, by a decomposing action, prepares the way for other agencies. When the infiltrating waters contain traces of carbon dioxide, the feldspar acted on first loses its lime, if a lime feldspar, by a combination of the lime with this acid; next, its alkalies are carried off as carbonates, if the supply of carbonic acid continues, or otherwise as silicates in solution. The change thus going on, ends in forming kaolin or some other aluminous silicate. The carbonate of sodium or potassium, or the silicate of these bases, may go to the formation of other minerals, and may supply fresh and marine waters with their saline ingredients.

passes directly to a series of tables covered with cocoa-matting and expanded metal. The tailing from these tables goes directly to waste and the product cleaned up is washed down a launder to a settling-tank, shown about the lower half of the photograph. All the sand and coarser material that passes through the $\frac{1}{4}$ -in. screen is taken directly to a second series of screens having circular holes $\frac{3}{16}$ in. diam., the oversize from which passes to another series of tables as before. The fine material going through is then passed through two sets of tables placed in tandem, and at a less grade than those for handling the coarser material. These are also provided with cocoa-matting and expanded metal.

At the commencement of operations, these tables were only cleaned up about once every 24 hours, but subsequent experience proved that to do so more frequently was advisable, and they were eventually cleaned up every $2\frac{1}{2}$ hours. The entire product resulting from these various clean-ups was passed by launders to settling-tanks, and as these became overcharged, the water was run off,

allowed to go to waste, we must certainly give Sanders & Hadly and Mr. Harvey credit for furnishing such a useful example to other hydraulic miners.

The criticisms which I have to offer and the suggestions which I would like to make are as follows: First, owing to the natural topography of the country at Mr. Harvey's mine, they were fortunate in obtaining a convenient site for the plant with almost unlimited grade for the dump, and water for power and other purposes, and it must be remembered that at every mine such facilities are not to be found.

Secondly, that while I think that they had the right idea when they attempted to size the product, it appears to me that they should have gone a step further and made the classification more complete and thorough. The cocoa-matting tables could then have been eliminated and the whole of the fine product less than $\frac{1}{4}$ in. could have been treated by the table concentrators, or it could have been first passed to hydraulic classifiers, using clean water, the coarse product being sent to table concentrators

and the fine to belt machines or canvas tables. The details of arrangement for different mines would have to be modified by experiment, to prove the proportions of valuable materials in the fine or medium-fine products. I think also that the table area with which they attempted to concentrate the product from the cocoa-matting, was inadequate for the task, and too crude and elementary in design.

An attempt was made with a shaking amalgamating table but it was abandoned, as it was found that a great part of the heavy grains of gold were so coated that they refused to amalgamate, that the table was to a great extent choked by a sheet of black sand, and that there was a considerable percentage of tin, copper, and

Upper Length of Sluice Boxes. Showing Step-Fault in Bed-Rock.

and the material dug out and stacked on the side. This material might be described as semi-concentrated, and here is where I see the greatest fault in the design of the plant. There appears to be a lack of continuity in the sizing process and also in the general plan of treatment. The whole of the material saved from these settling-tanks was passed over one single home-made concentrating table, the middling from which was re-concentrated and the fine run to waste.

The product from the concentrating table consisted principally of black sand. This was stacked in a settling-tank and dried from time to time on flat trays, the trays being placed over a roughly-built furnace. The dry product was then passed through a home-made magnetic separator, which appeared to work efficiently and satisfactorily. This removed practically all the magnetic iron, or more correctly speaking, the magnetizable iron sand, which has been stacked in a tailing-dump immediately below the shed, and, judging from a rough estimate I made, there is over 100 tons of this product. The rest of the material which was delivered by the moving canvas belt consisted of the usual by-products as shown by Dr. Day's experiments, and I am told that some of this material ran as high as \$1,000 per ton. When we consider that this product, which can be shipped and easily treated, has been concentrated down from sands and clays which were originally considered as tailing and

other base metals which entirely ruined the surface of the table. It therefore appears to me that if amalgamation is to be introduced for the purpose of saving gold in any part of a general process in which concentration enters, it should be applied in three separate and distinct methods, all subsequent to concentration:

1. If the gold is coarse and heavy enough to be caught by concentration, this is a more economical and rapid process than amalgamation. If the gold is so light and flaky that it readily passes over the surface and is not caught by the riffles, it is self-evident that it will be easier to amalgamate the light gold by some independent amalgamating device after the heavy concentrate has been removed. I would therefore insert an amalgamating device to treat the tailing of the concentrator, in preference to treating the pulp before concentration.

2. The coarse particles of gangue and other middling commonly to be found in the tailing of a concentrator, generally carry some fine gold actually imbedded, and as a general rule this fine gold is free and is not associated with base metals. While its weight, when associated with the enclosing gangue, is not sufficient to cause it to be caught by concentration, its weight, when liberated by regrinding these particles of gangue, is sufficient to enable it to be caught in any good amalgamating device, and as a rule the gold liberated by regrinding will freely amalgamate and cause no further trouble with the copper

and was considered first-class in every respect. The average hydraulic miner would certainly have stated that, if any gold was being lost, it was of such a nature that it could not be saved at all.

The successful working of the black sand plant eventually installed has shown the matter up in a different light. This description covers the most important points of interest with regard to the equipment of the mine.

The actual operation of mining is carried on much as usual, with the difference that Mr. Harvey makes the rather exceptional practice of mining 'left and right' of the nozzle and keeps a sloping nose of gravel immediately in front of the giant, thus being able to keep the giant right up to within 60 ft. of the high bank, without undue risk of a cave in front of the work. This method also allows an efficient side-cutting action to be used with the stream when undercutting.

Before giving a description of the black sand plant, I think that a few remarks on the subject may tend to give a clearer understanding of the problems to be faced, as much prominence has recently been given to the black sand question, on the one hand by careful scientific work by capable and reliable men, such as Dr. Day, and on the other hand by a lot of cheap newspaper rhetoric, written by men who have no real knowledge of the subject, and which has aroused adverse, and no doubt in some cases, just criticism.

First and foremost, the general argument put forth by all old-time miners is that, if you do not catch any gold in the tail end of your sluice-boxes or in your undercurrents, you are not likely to catch it by any other means that you may devise. This has always seemed to me to be an argument representative of ignorance and prejudice. Gold of all sizes and in particles of nearly every conceivable shape is found disseminated through the gravels of a placer mine. In some cases it is almost perfectly pure, has a clean surface, and will readily amalgamate. In other cases, it is so coated and foul that you may shake it in a bottle of amalgam and again separate it almost untouched. Some of the gold is flat and flaky, and if caught on its edge will travel for a considerable distance in a swiftly flowing current of water before getting a chance to settle, and I have noticed, in actual hydraulic mining and in experiments which I purposely carried out to determine the question that gold is transported for greater distances before settling, if the water is foul and muddy, than if the water is clean. I made the experiments by taking a known amount of fine gold grains and throwing them into sluice-boxes carrying both clean and muddy water, making a clean-up a few minutes afterward. Using foul water, heavily charged with clay, I found that in nearly every case a considerable amount of the fine gold was carried away, although in some of the tests this gold had been caught in the same sluice-boxes, using the same riffles and grade.

It appears to me that the research work which Dr. Day has carried on is not really of much value to the average hydraulic miner. Dr. Day merely carried out a series of thorough tests to see if certain samples of black sands submitted to him carried valuable metals, and principally to find out if they carried any platinum. I think it is generally accepted that black sands are nearly always associated with gold, though I could show anybody who wished to see it, great quantities of black sand which can be panned out from streams, in which I have never been able to find the slightest trace of gold, even by an assay. The gold, platinum, and black sands are commonly associated with each other merely by virtue of their specific gravity, and I do not think that any experiments or tests have so far proved or even pretended to prove that the gold is in direct combination with the

black sand, but have merely gone to show that if you wish to save the fine particles of gold and platinum it is necessary to save all the associated minerals having a high specific gravity, and subsequently to separate the gold and platinum from the less valuable iron grains.

Dr. Day's work has been mostly along this line, but what the hydraulic miner chiefly requires to know is, not so much how to separate the valuable materials from the black sand (that being an after consideration and within the province of a metallurgist) as to know how to save the black sand itself with its associated gold and platinum, and separate the same from the enormous bulk of sand, clay, and gravel.

The hydraulic miner's pan and sluice-box are, after all, nothing more nor less than a crude wet-concentrating device, in which no attempt has been made at classification before concentration. It is the experience in nearly all concentration plants that have been erected for the successful treatment of pulp from mills, that the question of sizing is an important one, and that if the grains or particles vary by even 3 or 4 diameters it will lessen the efficiency of the concentration. How much more then must we expect this effect where quartz boulders 12 inches in diameter are bumped through a sluice-box in a stream of water having a velocity of 15 ft. per second or more, and attempt, at the same time, to throw down and catch a grain of gold which can be passed through a 100-mesh screen. Furthermore, the miner's sluice-box is a concentrator in which the products accumulate and are only removed at stated intervals, that is to say, the process is not continuous, and the black sand (which in some cases amounts to 30 or 40 lb. per cu. yd.) has a tendency to rapidly cover the surface of the quicksilver in the riffles, to choke the bed of the riffles, and allow the fine gold to be washed over them, and in consequence, to run to waste.

At the beginning of last season's run, Sanders & Hadly in conjunction with Mr. Harvey, designed a plant for experimental purposes, which has been so successful as to pay for itself and leave a considerable net profit. Sanders & Hadly certainly deserve credit for the plucky way in which they have handled this problem, and the plant, although lacking in some details, has undoubtedly solved some of the most vexing questions of the problem. The accompanying photograph will give some idea of the general arrangement of the plant. Near the lower end of the main sluice-box, an undercurrent was inserted, having a grizzly built up in four sections, the first of which was a $\frac{3}{8}$ -in. stamped steel plate, the second consisting of bars placed $\frac{1}{2}$ in. apart, and the third and fourth consisting of grizzlies having $\frac{1}{2}$ -in. slots and V-shaped bars. All of the fine product from the gravel does not pass through this grizzly, but the amount to be handled approximates, as nearly as we could estimate, 2,000 cu. yd. of material, varying from flat pieces of slate $\frac{1}{4}$ in. thick and 1 in. long, down to the finest mud. This would represent from 3,000 to 4,000 tons of material to be treated per 24 hours, and considering the low value of the product, probably not more than a few cents per cubic yard, it requires some careful and ingenious planning to handle this material at a low figure and without an undue initial expenditure, and this is the largest plant of its kind in existence for the successful concentration of low-grade material on a large scale.

The product as received from the undercurrent grizzly is transported in a flume to a distributing box placed at right angles to the flume, and which forms the head of the whole plant. This distributing box serves to regulate the flow of sand to a number of different sieves, consisting of flat steel plates punched with round holes. The first lot are punched with $\frac{1}{4}$ -in. holes, and the over-size

The Hydraulic Equipment of the Old Channel Mines.

Written for the MINING AND SCIENTIFIC PRESS
By JOHN M. NICOL.

The Old Channel mines were first discovered in 1865. This enormous deposit of auriferous gravel may be traced for about 15 miles, having a general north and south direction.

The bedrock consists of black shale and reddish colored mica schist. The schist is much contorted and the stratification is on edge. The level of bedrock averages about 500 ft. above the Rogue river, with an elevation of about 1,100 ft. above sea-level, so that the mines have magnificent facilities for dumping the tailing.

The gravel banks vary from 50 up to 250 ft. in thickness, and are from 200 to 600 yd. wide. The gravel is fairly even, and although in some places a few coarse pebbles and large boulders have been found, nearly all of the material can be put through the sluice-boxes.

There are seven large gulches that cut through the formation at right angles, and it was in these gulches that gold was first discovered, and the early work of placer mining carried on. The gulches have been excavated clear through the gravel and through the slate bedrock, and offer a number of different points at which to commence mining and in which to dump the tailing.

A good idea can be formed of the size and depth to which these gulches have been excavated by the action of running water, on referring to the photograph showing the dump at the end of the sluice-box, and which gives a good idea of the age of the deposit.

These mines have been worked continuously for 30 years, and are at present owned by the Old Channel Mining Co., and leased by John R. Harvey, of Grants Pass, Oregon. Mr. Harvey has been working the mines on a large scale for the last three years, and some information regarding his plant and the methods of working may be of interest.

The present plant consists of a ditch 12 miles long, measuring $8\frac{1}{2}$ ft. wide on top, 5 ft. wide on the bottom, and with a minimum depth of $3\frac{1}{2}$ ft., and a grade of half an inch per rod. The water is taken from Galice and Mill creeks, and the average flow for nine months in the year is from 4,000 to 5,000 miner's inches. There is also an extra flume, which brings in the water from Rocky gulch, and during the early winter rains, and while the snows are melting, this gives an additional flow of 1,500 miner's inches, enough to run one giant.

The ditch delivers to a small reservoir, and this in turn empties into a lower reservoir, from which the water is taken by means of two pressure-boxes and delivered to two separate pipe-lines. The value of the additional water supply from Rocky gulch, and the reserve of water in the two reservoirs can scarcely be exaggerated, for it will often happen during dry spells that the main ditch does not supply sufficient water to run all three giants and maintain the pipes full, in which case trouble would probably result, whereas the slight additional amount is sufficient to tide over the shortage of the main supply during the dry season.

The main pipe-line is 24 in. diam., and has an intake of 48 in. diam., and a total length of 2,600 ft. This supplies water under a head of 510 ft. to three No. 4 Hendy giants, using 6-in. nozzles.

Mr. Harvey informs me that when work is running full blast, they are able to break down and put through the sluice-boxes from 6,000 to 7,000 cu. yd. of gravel per 24 hours, and the average cost of working the gravel from grass roots to bedrock, allowing for expenditures of all kinds for a season's run, does not exceed 3c. per cu. yd.,

and averages 2½c. I am also informed by Mr. Harvey that the company owns about 900 acres of patented land in heavy gravel and about the same amount in minor claims, and as they own the most valuable water-rights available in the neighborhood, it may be roughly stated that their holdings cover the facilities for working between 3,000 and 4,000 acres in this neighborhood, which probably could not be worked by any other means, as pumping from the Rogue river to the height necessary to supply water under pressure for mining these gravels would be a serious undertaking and one involving a large outlay of capital.

Until about 15 months ago the methods in use for saving the gold were identical with those used on hydraulic

Old Channel Mine, Showing Grade and Dump Available.

mines from the earliest times, and consisted of a bedrock race which discharged into a sluice-box 5 ft. wide, 3 ft. deep, and having a total length of 1,200 ft. The first 90 ft. had a grade of eight inches in 12 ft., and the remainder a grade of seven inches in 12 ft. This sluice-box, in turn, discharged into a bedrock race.

There is a drop of 10 ft. at the end of the sluice-box that serves to break up any blocks of cemented gravel and to more effectually wash and free the material. After passing through 120 ft. of race, the gravel goes into a second line of sluices, having an average grade of twelve inches in 12 ft., a width of 5 ft., and a depth of 3 ft. The gold-saving device consisted of block riffles, 10 in. thick and spaced about $3\frac{1}{2}$ in. Quicksilver was used and clean-ups were made at the usual intervals. This arrangement was up to the usual standard of efficiency,

plates. I therefore recommend that the tailing from the concentrating tables be separated by hydraulic classifiers and the coarse particles, which make a small bulk, may then be conveniently reground and passed to some amalgamating device.

3. The concentrate may be treated by pan-amalgamation after the removal of the black sand by means of magnetic separators, provided there is not an excessive quantity of platinum or other valuable by-products, which may preferably be removed by other means.

The above are merely suggestions, based upon the results of observation and experiment, and by such means we should be enabled to make a positive saving by amalgamation, that could not be carried on as economically, simply, or efficiently by other means. I am referring more especially to the treatment of the products of a placer mine.

As I am following up this question of saving gold from hydraulic mining operations, I hope soon to be able to present some further data relative to this subject, and I shall be glad to receive criticisms on the foregoing observations, and to hear of the results and experiments of other men in the same field.

PRODUCTION OF QUICKSILVER.—The principal foreign quicksilver producing countries are Spain, Austria, Italy, Russia, and Mexico. Together with the United States, they practically supply the quicksilver markets of the world. In Spain the output of the famous Almaden mines is supplemented by the product of smaller deposits in the provinces of Almeria, Granada, and Oviedo. This country was for many years the leading producer, but in 1904 it was outranked by the United States. Most of the Spanish quicksilver is exported to London. The Idria mines in Austria are steady producers and make an annual output of from 510 to 550 metric tons. In Italy the annual production of the quicksilver mines of Tuscany varies from 300 to 375 metric tons. The most important mine is the Siele, near Castell, Azzara. There has been considerable activity in the district, and new mines have been opened at Badia, San Salvador, and Montebruno. All indications point to a steady, if not an increased, production from this province. The Russian output of quicksilver comes from the mines of A. Auerbach & Co., in the Ekaterinoslav district. These mines have produced 400 tons per year of the metal, most of which was exported to Hamburg, Germany. In Mexico the principal deposits of quicksilver ore are at Huitzuc, in the State of Guerrero, and at Guadalcázar, in San Luis Potosí. There are also very promising deposits in Querétaro and Guanajuato; and the States of Morelos, Jalisco, Mexico, Hidalgo, Zacatecas, and Chihuahua also possess numerous smaller deposits. Small quantities of quicksilver are annually produced in the mines of Huancavelica, Peru; in the Wang Shan Chang mines of Kweichow, China; and from the Taghit mines in Algeria. Quicksilver occurs also in British Columbia, Japan, Germany, Turkey, and New South Wales.

URUGUAY MINES.—The principal source of Uruguay's wealth is live stock, but the country is said to be rich in minerals. So far this source of wealth has been almost entirely neglected. With the exception of granite quarries in various parts of the country and four gold mines at Cufiapirú, in the department of Rivera, the mineral deposits have not been worked. In the past year, however, great interest has been manifested by mining men in the possibilities of various goldfields, supposed to be rich in high-grade ore. Several mining engineers and prospectors from South Africa and elsewhere have reported on the prospects.

Uses of Antimony.

Undoubtedly the chief use of antimony is for alloying with other metals for the purpose of making a lustrous hard mixture. Type metal contains from 17 to 20% antimony, in addition to lead and bismuth. Britannia metal is an alloy of 10% antimony, and 90% tin. Pewter contains 7.1% antimony, 1.8% copper, 1.8% bismuth, and 89.3% tin, and is employed for certain tableware. Aluminum-antimony alloys are being made; they are hard, tenacious, elastic, malleable, take a high polish, and resist atmospheric corrosion. Nickel, copper, silver, tungsten, and other metals will readily combine with aluminum and antimony, these alloys being used for special castings. Lead when alloyed with antimony and metallic sodium has unique non-corrosive properties, is strong, and rolls better into sheets and wire. This alloy may be soldered by the ordinary soldering iron with the use of the blowpipe. This alloy has been made as follows: The antimony is melted in a crucible, and the lead added; the metallic sodium is next introduced, and the whole is then stirred energetically. The mixture, containing 1,000 lb. lead, 15 lb. antimony, and 1 lb. sodium, is then cast into molds. Zinc readily unites with antimony in all proportions, forming alloys which are brittle and fusible. When alloyed in equal parts, antimony and zinc are of a bright sky-blue color, and have the peculiar property of writing on glass. Antimony-zinc alloys are employed in a small way in thermopiles. The various patented antifriction metals used for high-speed machinery contain antimony. The attention of inventors seems to be devoted mostly to the discovery of an improved economic method of recovering antimony from its various ores, and of refining the metal to a high tenor of purity. The preparation of alloys offers a field for profitable research, and among the minor specialties is antimonial plating. According to one patentee, antimony compounds may be recovered from pulverized ore (especially stibnite), by treating in a heated solution of 2% caustic soda. The process proceeds in a cycle, the alkaline solution first acting on the ore, then being formed into a carbonate, and then becoming re-causticised repeatedly. By another method antimony oxide is prepared from stibnite by treating the pulverized ore with sulphuric acid in the presence of sodium or potassium sulphates, and after allowing the substance to cool, boiling it with water until it is decomposed. Antimony oxide is left, and the acid released is used over again. Another patent electrolyzes antimony trifluoride in a cell having the impure antimony as anode. A process for coating metallic articles with antimony by immersing them in antimony powder, and heating the mass, has also been patented.

THE centre of the Georgia marble industry is Tate, about 50 miles north of Atlanta, in Pickens county, on the main line of the L. & N. railway. Tate lies among the hills, in a little valley formed by one of the sources of the Etowah river. The whole valley, and several of the enclosing hills, are practically solid marble, ranging in color from pure white to dark Creole, with many variations of shade between. The deposits have not been exploited for more than 175 ft. below the ground, owing to their large surface area. The marble is popular for building uses in all parts of the country. Its low absorption of moisture, about six one-hundredths of one per cent, renders it practically impervious to weathering in any climate. In this particular, microscopic tests have shown that this stone resembles closely the marbles of Greece. Georgia marble shows a crushing strength of 12,000 to 15,000 lb. per square inch.

A Concrete Tank to Store Tailing.

This large concrete tank is for the purpose of retaining the tailing of the No. 6 concentrator of the Arizona Copper Co. It is circular in shape and divided into four equal compartments. In the centre is a three-movement cantilever crane (built by the McMyler Mfg. Co., of Cleveland, Ohio), controlled from the base in a revolving motor-room, and operating a large double-jawed bucket suspended from the upper end by $\frac{7}{8}$ -in. cable. The entire outer edge of the tank is followed by a fixed launder, while a movable launder, working on rails, covers the inside, and may be moved to connect at any point to the fixed launder, thereby making it possible to throw the tailing to any desired spot. Under the tank, sunken launders, with screens, enable the clear water to be drawn free of tailing, run into other tanks, and pumped

THE DEVIL'S TOWER QUADRANGLE.—This quadrangle includes about 850 square miles in the northeastern part of Crook county, Wyo., its northern limit being the Montana-Wyoming State line. Its southeastern two-thirds lies in the northern extension of the Black Hills uplift, and its northwestern portion extends into the Great Plains, so that its topography exhibits features of both regions. Elevations within the quadrangle range from 3,500 ft. above sea-level in the plains region to 5,800 ft. at the highest point of the Black Hills area. The quadrangle includes portions of the valleys of Belle Fourche and Little Missouri rivers, the Little Missouri heading within it. The most notable feature of the region, and one of the most conspicuous topographic forms in the entire Black Hills area, is the mass of igneous rock from which it is named—the Devil's Tower—which stands on one of the ridges west of the Belle Fourche. About 100

Concrete Tank to Store Tailing.

by two 3-plunger pumps (made by the Deming Co. of Salem, Ohio), driven by two 10-h.p. direct-connected (National Electric Co., Milwaukee, Wis.), high-speed motors, back to the tanks above the concentrator for use over again. The compartment containing the dry tailing is being emptied by the crane, taking the tailing and putting it into two bins at the bottom of a 15-ft. gravity incline, by which it is then hauled to a large bin at the top of the mill, from where it is carried by Humphrey electric motors to the Longfellow, Humboldt, Clay, and other mines of this company to be used as filling. This method of disposing of the tailing problem has proved a decided success, and as a result, the litigation started by the farmers of the Gila valley has been stopped, they having claimed heretofore that the tailing in the irrigating water from the river was ruining their land. The idea of this tank was conceived and carried out by C. D. Clark, who built the No. 5 concentrator for the Arizona Copper Co., and who is the representative of a London company at Mandalay, in Burma.

ft. in diam. at the top, almost circular in form, and with sides nearly vertical, it rises 600 ft. above the sandstone platform that forms its base and a little less than 1,250 ft. above the river, which runs a short distance to the east.

IRON IN TALLADEGA COUNTY, ALABAMA.—The gray iron ores of Alabama occur in a belt that is confined almost entirely to Talladega county, and although this belt of ore has long been known, but little attention has been paid to it as a source of iron. The only company now in active operation in this region is taking out ore at but one locality—the Mesaba or Tallaseehatchee mine, on Tallaseehatchee creek. Practically all the so-called gray ore is hematite, but in places the percentage of magnetite is so large that the ore is somewhat magnetic. Its name, derived from the ashy gray color which it takes on weathering, not only describes it but serves to distinguish it from the brown or red ores of the northern part of the State.

Keeping Account of Supplies.—II.

Written for the MINING AND SCIENTIFIC PRESS
By MATT. W. ALDERSON.

The importance of a system that will prevent any possible leaks from illegitimate causes around the mine should be apparent to every prudent manager. Even though it does cost a little time and money, it will save money in the end. And the system I outline will actually require less time and attention than some in use that do not accomplish good results. Thus, at most mines candles are issued every morning to the men as they go to work. My practice is to issue to them once a week only. Each man as he goes to work Monday morning receives 15 candles—more than he will need, but enough to provide a reserve for any unforeseen emergency. If he is working in a part of the mine where it will be advantageous for him to have his own powder-thawer, he is furnished with one, and with 36 sticks of dynamite, 100 ft. of fuse, and a box of caps.

Where several men work in one place, as where two or more shifts of two men each are making a drift or where several men are working in one stope, I issue to the group, designating one man to receive the supplies and report. The amount used each week is then divided by the number of men, to find the average for each man. Saturday night, as each man comes out of the mine, he stops at a desk in the shaft-house and fills out a ticket as follows:

SUPPLIES ON HAND.

Saturday eve1907

.....candles

.....sticks dynamite

.....feet fuse

.....caps

.....Name

If he receives only candles, he fills in for that one item. No entry is made on the lines for 'feet fuse' and 'caps' until these are down to where the miner has not enough to last him the coming week. Each man hangs his ticket on a wire and departs. The foreman (or storekeeper) takes the tickets, makes entry in a book kept for the purpose of recording supplies used, and lays out what is needed for each man, so that he starts with the same amount on the second and succeeding weeks.

Monday morning, as the miner goes to work, he finds on a shelf arranged for the purpose, a sack similar to those used by school children for carrying their books, in which are his dynamite and candles, the latter wrapped in a newspaper. I have used ore-sacks and at other times the lower halves of burlap grain-sacks to hold these supplies. If caps are wanted, they are laid on the top of the sack so that the man can pick them up and put them in his pocket. The sack is tagged and if there are many employees, the sacks are arranged in rough alphabetical order, so that each man can quickly find his own.

This arrangement involves fixing a place near where each man works, in which he can keep his supplies. If there are rats in the mine, the candles and dynamite must be kept under cover. I use a candle-box, an ordinary fruit-box, or a dynamite-box, make a partition in it so that candles may be kept on one side and dynamite on the other, and put on a lid. The caps and fuse can be kept in a nook by themselves and will not be molested. Rats nibble at fuse sometimes, but seldom enough to injure it.

Where several men have access to the same dynamite-

thawer in the mine, I charge the thawer with the supplies that go to it from the storehouse. On a board near the thawer is a sheet whereon each man enters the number of sticks he takes, a pencil for making the entries being conveniently suspended by a fine chain. These sheets are gathered each Saturday night and new ones put in their places. The person taking them up notes on the sheet the amount of dynamite in the thawer, so that the foreman has a check on the figures put down by his men.

RECORD OF DYNAMITE USED ON THE FIRST LEVEL OF
THE SNOWDRIFT MINE
FOR THE WEEK ENDING JULY 20, 1907.

Name of Miner.	Mon.		Tues.		Wed.		Thur.		Fri.		Sat.		Total
	v	d	v	d	v	d	v	d	v	d	v	d	
	u	m	u	m	u	m	u	m	u	m	u	m	
Geo. White.....	3	2	4	2	2½	3½	1	4	1	3	1½	3	30.5
Herman Dahl.....	1	1	1	2½	4	3½	4	1½	2	2	22.5
John Smythe.....	2½	1½	2	1½	2	3	2½	1	2½	1	2	2	23.5
Thos. Fox.....	3	4	7	3½	4½	5	27.0
Totals	6½	7½	7	10	4½	17½	3½	12	7½	10	5½	12	103.5

In thawer, 87.5 sticks.

When the results are tabulated, on the last Saturday of each month, it is a good idea to make copies to place on the bulletin board. Separate tables should be made for men that are working under different conditions, as where one uses his snuffs to warm the water of his powder-thawer and another does not; and where one is breaking ore and another driving in barren ground. The tables will show the men that the manager is attending strictly to business and knows exactly what is going on, and that the men are judged not alone by the amount of powder they use, but by what is accomplished with it. These reports will be an inspiration to the best men and should encourage those behind to make a better record. My idea is not to skimp the men, but to get them to use their intelligence and to practise reasonable economy. Many a man who goes after powder, who would take 30 sticks for a round of holes made with a machine, might think 25 would do nicely if he knew the boss was keeping account of just what he used every day. It may be more economical to use sufficient powder to break ground fine than to 'bulldoze' masses left by breaking with too small a charge. The manager is not parsimonious when he adopts vigorous measures to eliminate waste. The candle snuffs with which the miner starts his fires in the winter are not justly chargeable to the expense account of the mine, and the stick of powder that the miner uses for tamping, after the hole has been loaded with sufficient explosive, is just so much hard-earned money thrown away.

ALTHOUGH diamonds have been found in at least thirty places in the United States, the only locality where they occur in place has recently been discovered and has been investigated by George F. Kunz, the gem expert, and H. S. Washington, petrographer. They occur in an igneous rock, similar to that of the South African mines, which forms a small stock near Murfreesboro, Pike county, Ark. The first two stones were found August 1, 1906, and since then many of them have been picked up, the total number found at last report being 130. Many are white and of good water, others are yellow, and some are of brown bort. The two largest stones weigh 6½ carats, one being exceedingly fine white and the other brown. They are found on the surface as well as within the greenish, friable, decomposed peridotite, a rock somewhat like the famous 'blue ground' of Kimberley. The property is being actively prospected and developed.—*Science.*

be inserted. Derricks had to be erected, and electric wires strung for lighting the workmen on night shift. Fortunately, there was a railroad track across the flue

The ore treated in the Washoe plant comes chiefly from Butte, which is 28 miles from Anaconda. Most of the ore undergoes concentration. The fine concentrate

Fig. 2. Main Flue, June 4, 1907.

Fig. 3. Repairing the Big Flue.

where the cave-in occurred, so that transportation facilities were afforded.
The workmen had to be organized into three shifts of eight hours each, and means taken to provide them with hot meals during the progress of the work.

is briquetted. Roasting is done in an Evans-Klepetko modification of the McDougall furnace. Smelting is effected in blast-furnaces of immense size designed by Mathewson. One of these is 87 ft. long. The operation of the plant is conducted most efficiently.

Manufactured Graphite.

One of the most important electrical industries at Niagara Falls manufactures graphite from anthracite coal and petroleum coke and converts into graphite the forms of raw carbon used in electric furnace work, where high temperature is required, and for electrolytic work, such as the manufacture of caustic sodas, bleaching powders, etc.—in fact, practically all methods of electrolysis. The raw materials used consist of anthracite coal, glass sand, foundry coke, and sawdust, all of which are imported from the United States, except the sawdust. The furnaces used for the conversion of the anthracite coal or petroleum coke into graphite are in the form of long narrow troughs, built of fire-brick and lined with some suitable refractory or insulating material. In this case the sand, coke, and sawdust are used for insulating, by mixing them together in the proper proportions. At the end of each trough is a terminal built of carbon rods, to which is connected the cables conveying the current. The trough is filled with anthracite coal, in which is embedded a carbon rod to make electrical connection between the terminals, as the coal is a very poor conductor of electricity. The temperature to which the coal is raised before conversion into graphite is very high, and is said to approximate 7,500° F., a temperature at which all bodies except carbon are vaporized and driven off. It is possible to make the graphite practically chemically pure, but for ordinary commercial purposes such a high degree of purity is unnecessary, but it is possible to so regulate the operation that a degree of uniformity of purity is attained which is not possible to secure in the production of natural graphites. When the furnace has cooled sufficiently the graphite is removed, but it is not yet in commercial form and has to be ground to powder and finally separated into the sizes necessary for the various uses to which graphite is put, one of the most important of which is its application as a protective coating for iron and other metal structures. During 1906, 454,311 lb. of graphite were manufactured here, the greater part of which was exported to the United States. The demand in Canada, though steadily growing, has not warranted the construction of a complete grinding factory such as would be necessary to make all the forms and grades ordinarily required in the trade. In comparison with the production of graphite in this manner, the quantity mined in Canada is surprisingly small, the report for 1905 showing that only 541 short tons were mined, valued at \$17,032, while the value of artificial graphite for 1906 was \$21,579.

CHILEAN NITRATE.—The export of nitrate from Chile in 1906 of 17,279,651 metric quintals, of 220.46 lb. each, was valued at \$84,520,035. The cost of exploitation per Spanish quintal of 101.6 lb., delivered on board and including the government tax of 28 English pence per quintal, as given by the different countries, varies from P4.4 to P5.17. As the product is worth about P9 per quintal, this shows an average profit of nearly 50%. La Asociación Salitrera de Propaganda, which regulates the exportation and quota of each company, when arranging for the year ending March 31, 1907, authorized an exportation of 43,000,000 quintals.

Quick Repairs to a Smoke-Flue.

By the courtesy of Mr. E. P. Mathewson, general manager of the Washoe works of the Anaconda Copper Mining Co., we are able to give some interesting notes on the quick repairs done to the large smoke-flue of that important smelting establishment.

At 9 A. M. on June 4, 1907, 108 ft. of the roof of the dust-chamber, 60 ft. wide, or main smoke-flue, at the Washoe smelter, suddenly collapsed. The smoke from all the smelting operations passed through this flue; consequently, all smelting operations were stopped until 5 P. M. June 6, when the flue was repaired and work resumed.

The construction of the flue at this point is shown in Fig. 1. The columns are 12-in. I-beams, the stringers 15-in. I-beams supporting 7-in. I-beams that act as purlins extending from wall to wall. The 7-in. I-beams are

Fig. 1. Showing Construction of Flue.

spaced 42 in. centre to centre, and between them 4-in. brick arches are laid. The 15-in. stringers are bolted to the caps of the columns by eight $\frac{3}{4}$ -in. bolts, four at each end. The failure of the construction was due to the shearing of these last mentioned bolts by expansion.

In the repair construction, trusses were placed on brick pilasters, and from these the stringers and purlins were supported. Two of the trusses are shown in Fig. 2. The material is being prepared for the continuance of this style of construction, to replace the old form, as rapidly as possible.

Fig. 3 shows one-half of the opening caused by the cave-in of the flue.

To give an idea of the damage and the amount of work necessary to repair it, the following figures are quoted: An opening, 60 ft. wide and 108 ft. long, had to be covered; 216 ft. of 15-in. I-beams had to be punched with four $\frac{3}{4}$ -in. holes every 42 in. to receive 8-in. purlins, which were put in place of the 7 in. formerly used, and also punched eight holes for column connection, and 10 holes for splicing plates on each beam. Two 60-ft. trusses had to be made. The eleven 8-in. and twenty-one 10-in. I-beams were used in place of the 7-in. I-beams for the roof purlins. All these I-beams had to be spliced, as the material on hand was too short. Between the purlins, corrugated iron centres for a temporary covering, as well as for the brick arches, had to

ft. per min. with a clear shaft, but as much of the area would be taken up with cages, pumps, etc., the velocity would have to be greater than this. As another example, with 1,000 persons in the mine, 150 cu. ft. to each person, 150,000 cu. ft. per min. would be required; this amount would reduce the velocity to about 890 ft. per min., so that a shaft should not be less in area than this if required to pass a sufficient quantity of air for 1,000 persons to a depth of 2,000 ft. As another illustration, to pass 35,000 cu. ft. of air per min. through a shaft 8 by 4 ft., 1,100 ft. deep, would require 42 hp. and a pressure that would run the water gauge up to $4\frac{1}{2}$ in., which is too high for economical operation; this shows that the shaft is too small for the amount of air requisite to good ventilation, unless a mechanical device is used by means of which, as illustrated, the amount of air passed through

so as to give a sufficient supply to every working place in the mine.

An exhaust fan of 250,000 cu. ft. capacity is shown in Fig. 1, on the surface and connected with the vertical hoisting shaft; in order to gain a larger area, another air course is shown by dotted lines, from the 1,000-ft. level up through the vein. If this is made of large area it will materially assist the work of the fan, thereby reducing the power required for its operation. On the 1,000-ft. level is shown another fan of 120,000 cu. ft. capacity, the discharge being through an air course, at an inclination with the shaft, thus acting as a jet, and creating a suction to draw the air from the lower levels, at the same time assisting the surface fan.

It being generally understood that air becomes heated in traveling down from the mouth of the downcast

Fig. 2. Plan of 2,500-Ft. Level.

the shaft may be three times greater than is possible by a system of natural ventilation.

With the natural system of ventilation, to insure a sufficient supply of air shafts and airways must be made at least three times larger in area than may be used to advantage with mechanical ventilators; and it is an impossibility to thoroughly ventilate a group of mines as illustrated in Fig. 1 and 2, employing 1,000 men underground at the depths indicated, by natural ventilation, unless all the shafts and air courses are made three times the area, or the number trebled.

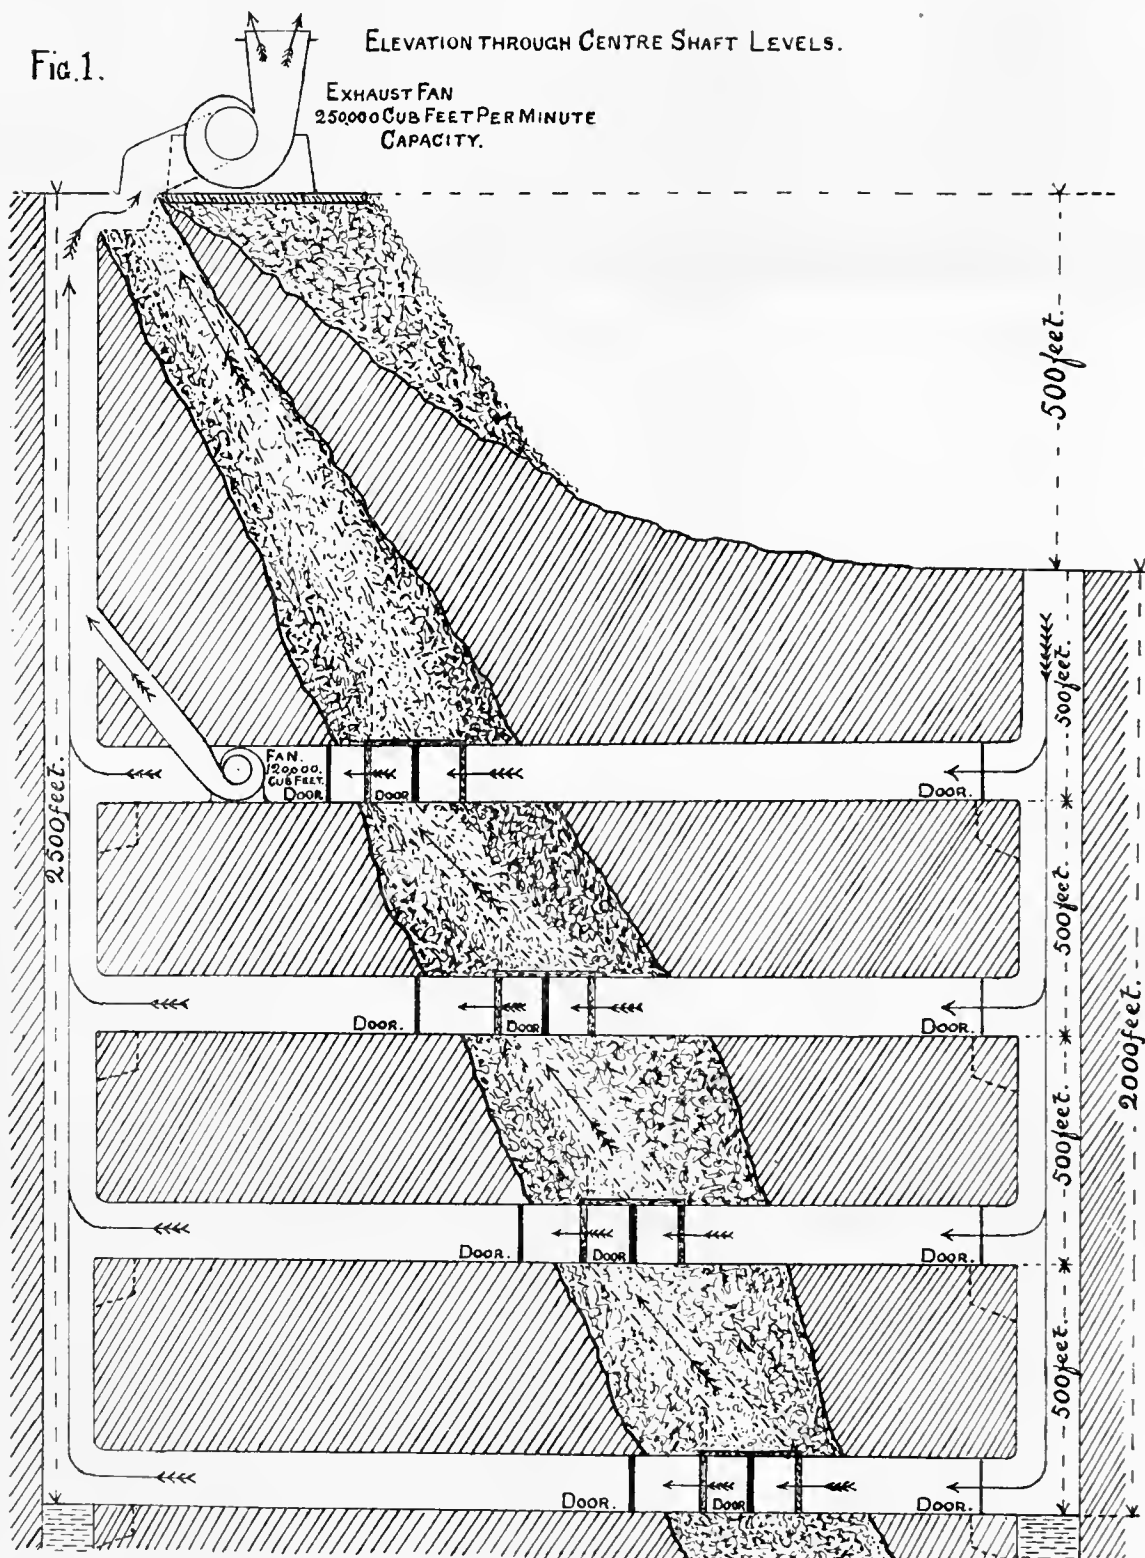

These illustrations are given to show how such mines may be ventilated by the vacuum system, with mechanical ventilators, adapted for supplying air in mines (especially quartz mines), with shafts and airways so small as to be inadequate to allow of proper ventilation by any other means, and this only may be accomplished by regulating the air currents by doors placed as shown, the course of the currents being indicated by the arrows; by the proper use of these doors the air may be distributed

shaft and through the air courses, and at the same time expands from this heat, probably 10% in volume; this expansion reduces its weight per cubic foot, and makes it lighter than the incoming air at a lower temperature, and naturally causes it to rise to the upcast shaft, but as the air courses and shaft are insufficient in area to allow it to pass, it becomes humid and heavy, thus stopping the circulation. As the air becomes heated and expanded while passing through the airways, a larger volume must be passed through the upcast shaft; but since, as already noted, the shaft is too small, it would be useless to force more air into the mine, as in the forcing system, for by that every crevice would be filled with foul air which could not escape.

With the vacuum system the operation is entirely different as the exhaust fan is placed at or near the top of the upcast shaft, a suction is created by which all the foul air and impurities are drawn out of every part at a high velocity through the courses designed for that especial purpose, forming a vacuum, which induces a

the hurry to extract ore, the mine is often soon brought into such a condition that the foul air filling workings renders it impossible for the employees to accomplish a normal amount of work; under these conditions, satisfactory results cannot be expected. From this it may be inferred that ventilation has a much greater effect on the cost of extraction than would at first be imagined; there is no doubt but that the cost is doubled in many

As the quantity of air required by the laws of several States is 100 cu. ft. per man per minute, and in some cases 200 ft. per min., an estimate may be made from the number of men employed underground as to what amount will be required. If, in the mines illustrated by Fig. 1 and 2, there are 1,500 men employed, at 100 cu. ft. per man, 150,000 cu. ft. would be required; when a large area has been worked out more air is required, probably

mines, through the failure of the managers to provide an adequate system of ventilation.

The quantity of air required in every case cannot be stated, as an amount that would be adequate for a given number of men in a new mine would be inadequate in an old mine, with many unfilled places that require a larger volume of air in circulation to carry off the smoke, poisonous gases, and dampness from the old workings.

150 cu. ft. per man, or 225,000 cu. ft. per min.; this is a large volume of air to keep in circulation, and shafts and air courses must be of such size that the mine resistance will not require too high a pressure to move it.

Referring to Fig. 2, it will be seen that the downcast shaft, with four compartments, each 6 by 5 ft. and one compartment 10 by 5 ft., has an area of 170 sq. ft.; to pass 225,000 cu. ft., this would mean a velocity of about 1,300

Economy in Mining Operations.

Written for the MINING AND SCIENTIFIC PRESS
By THOMAS E. LAMBERT.

The operation of mines and the first step in development present many problems of great interest. When a mining property is under the management of a thoroughly practical man, the question is solved in accord with local conditions, and is a financial success if the pay-ore lasts. Others, the same object in view, disregard the vital necessities by giving too much attention to the first cost, underestimating the advantages to be attained from an obligatory expenditure in early development work. The opposite extreme is presented by other managers, imbued with exalted ideas of superiority, who recklessly put all the earnings of the mine into expensive, premature, and unnecessary work. Good sense avoids extremes.

It is not intended here to speak of the location and preliminary development of mining claims, but after the property has come into possession of a corporation, the question of the best plan for future operations must be placed in the hands of thoroughly practical men, and on their judgment the success or failure of the venture depends.

In order that the following remarks may be better understood, reference is made to the accompanying drawings.

At the outset care must be taken in tracing the direction and pitch of the vein; supposing a case in which the claims owned by the company are three in number, of 1,500 ft. each, end-lining one another, and a vein 10 ft. wide is proved to run through all the claims nearly parallel with the side-lines. Shafts should be sunk at points best adapted for opening up the property, and for permanent use after development has proved the value of the ground; in this case, a shaft should be sunk at each end of the group of claims, not less than 50 ft. from the end-lines, and a third in a central position. All these shafts should follow the vein and be not less than 8 by 4 ft. in the clear, if possible, with two compartments, boarded up close in the centre, so as to cause free circulation of air. The object in having large shafts is that the ore extracted will help pay expenses, they will be easier to sink, and if carried down to a depth of 1,000 ft., still following the vein, they will serve for the circulation of air in developing the property to that depth.

The work of sinking should be carried on simultaneously in all the shafts until they are down to the same level, but if ore is needed, connecting drifts may be started between the shafts at the 500-ft. level, wide enough for two sets of timbers, and boarded up tight between the sets, thereby aiding the circulation of air, which is of great importance in expediting the work. If the vein is large at this level, these drifts may be run in a straight line under the direction of a surveyor, by which a freer circulation of air is attained through all the workings.

The dip and size of the vein will be defined by these operations, and the value of the ore demonstrated, so that the advisability of sinking a permanent vertical shaft in the most suitable situation for hoisting and transporting the ore, may be determined.

The futility of sinking vertical shafts in the foot-wall of a vein is shown in Fig. 1, as the vein dips from the shafts, and the several cross-cuts lengthen at every additional level; it would be more advisable and economical to sink one large permanent vertical shaft, so that the vein may be reached by short cross-cuts. This shaft may be divided into four hoisting compartments, with a larger compartment to be used as a pump or sinking-shaft. The temporary hoisting engines, with capacities

of 1,000 ft., may be installed on each side of the shaft, so that in the event of further development being required, either hoist may be replaced with one of greater capacity, without interfering with the operation of the other. This shaft may be put down to the same depth as the 1,000-ft. level projected for the other shafts, and the cross-cut run to the vein before the temporary shafts have arrived at that depth, as in this instance the collar of the shaft, as shown, is 500 ft. lower, and the shaft will need to be but 500 ft. deep. When the vein is reached, the cross-cut is continued to the foot-wall of the vein, and then the proper place for the connecting drifts from each side may be determined, and they can be driven as rapidly as possible toward each of the end shafts; while this work is progressing, a raise may be started from the cross-cut to connect with the centre shaft.

By this time all plans and estimates should have been made for the permanent machinery and buildings, which may now be erected in readiness for continuous and economical operation. In some instances a large quantity of water is encountered that is expensive to handle, and if the amount should increase to such an extent as to necessitate the use of pumps, work must be stopped until connections are made with the centre shaft, and the lower permanent shaft cross-cut, as then pumps may be installed in the main shaft, making the lift only 500 ft. All later developments may be planned and executed from this shaft as the starting point.

When all the shafts and connecting drifts are completed on the 500-ft. level of the central shaft, stoping may begin and sinking should be continued until a point 500 ft. deeper is reached, when the vein may be tapped by another cross-cut, and connecting drifts run as in the upper level; connections with the shafts should be made by raising, as far as possible. If this work is pursued with dispatch, a good amount of ore may be extracted in development, without drawing on the reserves in the upper levels, which should be allowed to remain until the extent of the payable orebodies is determined, and the most practical and economical methods for its extraction and treatment have been decided upon.

In Fig. 2 is shown a plan of the 2,000-ft. level at the main hoisting shaft, all the shafts connected by drifts, cross-cuts, and raises, with a system of tracks by which the ore may be run out to the main shaft, and dumped into skip chutes, at a minimum cost. The shaft should be equipped with hoisting machinery of greater capacity than is immediately required, to provide for any possible increase in production.

In Fig. 1 an elevation is given that shows a vertical shaft sunk in the foot-wall, on the top of a hill, and a vertical shaft sunk to intersect the vein 500 ft. lower. It may be estimated how much may be saved by discontinuing the use of the upper shaft at the 1,000-ft. level, and hoisting from the lower shaft. The first cost in sinking 2,000 ft. and running long cross-cuts every 100 ft., the cost of hauling the ore to the shaft and then hoisting it to the top of the hill, where it must then be transported on the surface down to the same level as the lower shaft, all add greatly to the total mining cost. A study of this illustration should convince anyone that an enormous amount of money may be saved in opening and operating a mine situated as this one is, by following the above method of development.

One of the first things to be borne in mind in starting operations, is the question of ventilation, for upon this much depends; a good air supply is of great benefit to employers and employees alike, as with a perfect system of ventilation, more and better work can be performed. When this subject is misunderstood or disregarded, in

current of pure air to travel in the downcast shaft at a high velocity.

While in the north of England during the winter of 1905-6, I was invited to inspect a curiosity; it was called a 'Sirocco' fan, at Pelton colliery, county of Durham, and through the courtesy of Mr. Thompson, the mechanical engineer, I am able to give this information; the fan is 75 in. diam., and is placed about centrally between two large Guibal fans, one 30 ft. diam., the other 36 ft. diam., and is used alternately with the two large fans, exhausting over 220,000 cu. ft. of air per min., at a water gauge of about 2½ in., and doing 12½% more work; the air in circulating through the mines travels over five miles. It is a splendid illustration of the vacuum system.

There are several different designs of mechanical ventilators used; the Guibal has been the most extensively used for many years, and has given good satisfaction. The old system of furnace ventilation seems to have been abandoned entirely, it proving a reliable system for many years, but like everything else, becoming obsolete with modern progress.

Decisions Relating to Mining.

Specialty Reported for the MINING AND SCIENTIFIC PRESS.

Where a miner was injured by the falling of rock from the roof of the mine where he was working, in an action for damages it was held proper for him to prove by expert evidence the usual methods followed in the protection of the miners from danger by falling rock.

Spencer v. Bruner, (Mo.) 103 S. W. 578. (June, '07.)

A contract giving the privilege of entering on certain land for a term of years and drilling for gas or oil, and conveying a certain part of any gas or oil found, was held not to be a lease of the premises, but the sale of an option to exercise or not the privilege granted as the second party might choose.

Pittsburg & Co. Pav. Co. v. Bailey, (Kans.) 90 Pac. 803. (June, '07.)

A location on the discovery of a mineral-bearing vein, made on land subject to location, was not rendered entirely void because corners were not placed on unappropriated land subject to location; but such location was valid to the extent that it was within the marked boundaries and on unappropriated land.

McElligott v. Krogh, (Cal.) 90 Pac. 823. (June, '07.)

A mining location made in good faith, but which included within its boundaries more than the statute permitted, being more than 300 ft. on each side of the middle of the vein at the surface, was held to be void only to the extent of the excess.

McElligott v. Krogh, (Cal.) 90 Pac. 823. (June, '07.)

Where locators failed to place a monument at an intervening point on the line between the end monuments, as under their mistaken belief as to the accuracy of the location of the end monuments, there could be no necessity for it, they were entitled to have the line established on the correction of the location of one of the end monuments, which would include the corrected corner, that point, and the original corner not corrected, where no part of such line was more than 300 ft. from the middle of the vein: and on the correction of this corner, the court was not required to fix the boundary line as a straight line between the corner corrected and the original corner not corrected.

McElligott v. Krogh, (Cal.) 90 Pac. 823. (June, '07.)

Where the apex of a vein between two points was outside of the mining claim, and entirely within the boundaries of another, it was held that no extra-lateral rights in favor of the owner of such former claim could apply as to segment of the vein between such points.

McElligott v. Krogh, (Cal.) 90 Pac. 823. (June, '07.)

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The specimens sent from Rockland, Nev., by E. C. L. are: No. 1, Garnet; No. 2, Granite; No. 3, Andesite.

The specimens from G. W. O., of Twinning, New Mexico, are: No. 1, Diorite Porphyry; No. 2, Rhyolite.

The pebble sent by H. B., of Drew, Ore., is Magnetite in mica schist. The other specimen is Amphibole Schist.

W. W. C. sent from Galice, Ore.: No. 1, Graphite; No. 2, Quartz, Granite, Magnetite, and Pyrite; No. 3, Serpentine; No. 4, Serpentine; No. 5, Serpentine, Chlorite, and Epidote; No. 6, Quartz Schist; No. 7, Pyrrhotite.

F. S. C., of Villa Grove, Colo., sends: No. 1, Sandstone stained with copper; No. 2, Sphalerite and Chalcopyrite in a gangue of fluorite; No. 3, Sphalerite and Chalcopyrite in a gangue of quartz; No. 4, Argentite in quartz.

The specimens from M. J. S., of Palomas, Ariz., are: No. 1, Andradite and Quartz with seams of chrysocolla; No. 2, Hornblende, Mica, and Garnets in calcite; we could detect no tin or zinc; No. 3, Calcite; No. 4, much altered igneous rock; No. 5, probably a much altered Andesite.

The specimens sent by F. H. S. from Whycoomagh, Nova Scotia, are: No. 1, Quartzite; No. 2, Actinolite; No. 3, dioritic Gneiss; No. 4, dioritic Gneiss; No. 5, Chlorite; No. 6, Titanite; No. 7, granitic Gneiss; No. 8, dioritic Gneiss; No. 10, dioritic Gneiss; No. 12, dioritic Gneiss; No. 13, dioritic Gneiss; No. 14, dioritic Gneiss carrying reddish garnets; No. 15, quartz Schist carrying molybdenite.

The specimens marked H. L. S., Mexico, are: No. 1, Pyrrhotite; No. 2, Pyrite and Chalcopyrite; No. 3, Pyrrhotite and Chalcopyrite; No. 4, Pyrite and specular Hematite; No. 5, Chalcocite and Malachite in quartz; No. 6, graphitic Schist; No. 7, Andesite; No. 8, Andesite; No. 9, Andesite; No. 10, altered Andesite with amygdulæ of epidote; No. 11, Andesite; No. 12, Dacite; No. 13, Andesite; No. 14, Andesite.

SUEZ CANAL.—The navigable dimensions of the Suez canal are now practically double what they were 20 years ago, the superficies of the vertical profile having been increased from 320 to 580 sq. m. in the ordinary channel, and to 740 sq. m. in the numerous crossing places, the dredging being so carried out as to exceed the limits originally agreed upon. The tariff for laden ships, it will be remembered, was reduced at the beginning of 1906. In that year 3,975 vessels, with a net tonnage of 13,445,504, passed through the canal, as compared with 4,116 vessels of 13,134,105 tons in 1905. The mean duration of transit remains about the same, namely, 18 hours for all vessels, but the general effective rate for mail steamers is 15 hours. The length of the canal is 100 miles, and the ordinary rate of speed is 6¼ miles per hour. The use of the electric light is practically universal, amounting to 97%. Out of a total of 3,975 vessels, 2,333 were British, a decrease of 151 vessels as compared with 1905. British net tonnage was 8,299,931 tons, a decrease of 57,000 tons as compared with 1905.

The Fairmont Hotel.

A photograph of this splendid structure is reproduced here on account of its general interest and because it will emphasize the fact that San Francisco has a hotel fully worthy of her past reputation as a place of sumptuous rest. The photograph was taken just before the renovation of the building was finished. At the time of the earthquake-fire the Fairmont was being fitted for habitation and the conflagration gutted the building, without serious injury to the main structure. The hotel is now open and, under the management of the old Palace Hotel staff, it promises to perpetuate the tradition among mining men that San Francisco is a good compensate for the

Manjak.

Manjak is the local name applied to the glance pitch which occurs commercially, so far as known, upon the island of Barbados alone. Manjak is a variety of asphaltum which somewhat resembles gilsonite (nintahite) in appearance, but it is more brittle and friable. The material is reported as occurring in veins which vary in width from one-fourth of an inch to 30 ft. The veins have a general north-northeast strike and varying dip. The country rock is an argillite or shale which, in places, is so saturated with bituminous matter that petroleum has been produced by destructive distillation at the rate of 37 gal. per ton of shale. Manjak is a pure hydrocarbon

The Fairmont Hotel, San Francisco.

rigors of life in the mountains and deserts among which mineral deposits are exploited.

TOPAZ IN CEYLON.—Among the precious stones gathered from the widely distributed gem gravel of Ceylon, topaz is fairly abundant, but the bright yellow variety is absent. What is spoken of as topaz among Ceylon gems is the rarer and harder oriental topaz, or yellow sapphire. The name of 'king topaz' is applied to pink or flesh-colored sapphire. The true topazes of the gravel are either colorless or light green, occasionally also pinkish-yellow or yellow brown. The first variety is cut and sold under the name of water-sapphire, which belongs properly to iolite (cordierite); the name is entirely misapplied, as the true water-sapphire is blue. The green topazes are sold, with true beryls, as aquamarines. The pinkish-yellow stones closely resemble those from Brazil, but with the curious difference that while the latter turn to a clear pink on being heated (the so-called burnt topaz), the Ceylon stones are absolutely decolorized by heat. The source of the gems is not known, as they are obtained only from the gravel, but it must evidently be in the granite intrusives of the Balangoda group.

compound and is used in the manufacture of high-grade waterproofing, varnishes, and insulating compounds. The annual production of manjak in Barbados for five years was as follows: 1901, 1,168 short tons; 1902, 1,033; 1903, 728; 1904, 707; and 1905, 725 short tons. The price free on board cars given by the shippers was from \$30 to \$51 per short ton, according to quality. The official average value is stated to be \$42 per ton. The entire output of the mines is exported, there being no local consumption of manjak.

ARSENIC IN COKE.—For some time past efforts have been made in England to produce a coke free from arsenic, and the latest process is being commercially developed by the Arsenic-Free Coke Syndicate, Edinburgh, who are making arrangements for granting licenses for individual gas works or for districts. As practically applied, the process consists of sprinkling upon the coal, prior to putting it in the retort, a small quantity of common salt—about 2 oz. of salt to the ton of coal. In large works, where a coal breaker is in use, an automatic sprinkler can be fitted to spread the correct quantity over the coals.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

AUTOMATIC ORE-ROASTING FURNACE.—No. 864,330; William F. Oesterle, Marion, Indiana.

In an automatic ore-roasting furnace, a series of ore-roasting floors, each with an air-lock, with a series of rakes, one in each floor, said rakes each having a flap pivotally connected to the cross-bar of same, which flaps are alternately on either side of the rake teeth so as to keep the ore moving toward the delivery, with means for moving said rakes, said means comprising a car which has an automatic intermittent reciprocating motion.

FILTERING APPARATUS.—No. 864,308; David J. Kelly, Salt Lake City, Utah.

An apparatus of the character described comprising a closed tank, a carriage slidably mounted thereon, a support upon which the carriage is movable outside the tank, said carriage containing a filter medium, means for supplying a solution to the tank under pressure whereby the liquid matter is forced through the filter while the solid matter is collected upon the outside of the filter, means for delivering the separated fluid outside the tank, and an automatically operating stripper or scraping mechanism operating co-ordinately with the outward movement of the filter-frame carriage to detach the solid matter adhering to the filters.

APPARATUS FOR TREATING ORES.—No. 864,642; Joseph C. Hames, Goldfield, Nevada.

In an apparatus for the treatment of ores, the combination of a tank having a bottom of stone, and an agitator arranged in said tank crosswise of the same, and comprising a plow or muller of stone movable rectilinearly in the direction of its width to and fro over the said bottom of the tank, and a plurality of pipes movable with and extending down through the plow or muller at intervals in the length thereof to the underside of said plow or muller, and adapted to be connected with a source of liquid supply.

PROCESS OF SEPARATING ZINC-BLENDE BY FLOTATION.—No. 864,597; Auguste J. F. de Bavay, Kew, Victoria, Australia.

A process of separating zinc-blende particles from ore, tailing, and concentrate in a pulverized condition comprising the freeing of zinc-blende particles from the carbonates and other impurities by first submitting the material to the action of a chemical re-agent, and then discharging the material in a film-like manner into a body of water by delivering the material in a thin pasty condition in the presence of a stream of water upon an inclined surface extending to said body of water, and then separating the zinc-blende floating on the water from the remaining ore, tailing, or concentrate which precipitate in the body of water.

CRUSHER.—No. 864,573; Thomas L. Sturtevant, Quincy, and Thomas J. Sturtevant, Wellesley, Mass., assignors to Sturtevant Mill Co., Portland, Me., a Corporation of Maine.

A crushing machine the frame of which comprises two longitudinal side plates, a parallel intermediate plate, and front and rear cross-beams separate from but secured to said plates, combined with a cam-shaft having its bearings in said rear cross-beam.

MINE-CAR.—No. 863,971; Thomas M. Edmondson Los Angeles, and Duncan Ferguson, Havilah, California.

In a mine car, a box body having a partial end wall, hinge bars extending transversely of said wall, a gate provided on its ends with hinge rods, and gate jambs extending vertically across said end wall and adapted to bear against the ends of said gate.

Editorial.

WE ARE IN RECEIPT of two specimens of the gutter press—the *Critic* and the *Graphic*. Even of their own kind of drivel they are weak exemplars, for the first contains a foolish attack on Mr. Benjamin I. Wheeler, the president of the University, and the other is seemingly dedicated to the flattery of Mr. Patrick Calhoun. Mr. Wheeler wins more by the enmity of this type of journal than Mr. Calhoun from its support. We shall be glad if the publishers of these two sheets will cease sending them to us.

TURBINE STEAM-ENGINEERING has gained by the successful voyage of the *Lusitania*, which is likely to do even better under more favorable weather. With the successful application of the turbine in propelling a vessel of the largest size, there has been made a great advance in ship-building, and there is every reason to expect that the Atlantic voyage will be shortened to five days or under. In the meanwhile the turbine has scored against the reciprocating engine.

SCARE HEAD-LINES are often more amusing than startling. Thus the doings of the Mining Exchange in San Francisco are given an air of stupendous importance by the irresponsible scribblers of the daily press. Some quite insignificant transactions in Goldfield Consolidated are described by the *Evening Scream* as an "awful bear raid" and by the *Morning Howl* as a "semi-panic." As a matter of fact 1,500 shares changed hands (which does not mean that they were bought or sold) and the price sagged between \$7.55 and \$7.05. This constituted the "bear raid" and the "semi-panic." Stock exchanges perform a useful function, and the one devoted to mining stocks in San Francisco doubtless is a necessary institution, but if the small business transacted does not make it unimportant, the press reports assuredly make it ridiculous.

MACHINERY once erected usually stays on the mine for which it was bought. It is not often that mine operators confess to failure and are willing to move a plant elsewhere. And yet it is a commendable thrift that desires to prevent the loss due to leaving perishable material on an idle mine. For this reason we are glad to record the removal of two gold dredges from Colorado to California. The National and the Clear Creek dredging companies were organized to exploit the gravel of a stream not far from Denver; they failed, either because the testing of the ground by drilling was badly done or the cores were 'salted'; in any event, the returns from dredging entirely failed to confirm expectations based on the drill-holes. Each company built a dredge and it is these machines that are being deported

to Jenny Lind, in Calaveras county, on a tract known as the Dennis ranch, where the Calaveras Gold Dredging Company is at work. The Colorado companies have been consolidated with the Isabel Gold Dredging Company and they will try their luck on this side of the Sierra. We wish them good fortune. Dredging is a most satisfactory form of mining when conditions are favorable. These conditions are various. But dredging is no more free from possibility of blunders than any other form of human activity and it is no more an infallible investment than, for instance, mining on the Rand, which for many years was claimed to be vastly superior to any other type of gold mining. Mining is, was, and will be, to the end of time, a sane speculation or a silly gamble, but never an 'investment'. The element of risk is never eliminated; any statement to that effect as regards a particular mine is made only by the charlatan or the fool.

THERE IS an unconscious humor in the titles of articles that happen to be thrown together. Thus in the last issue of *Science* there is an address delivered by Theodore W. Richards at Berlin, in the presence of royalty; so it begins: "Your Excellencies, Your Magnificences, Ladies and Gentlemen." After the published address comes a review of 'The Warblers of North America,' but Professor Richards is not mentioned specifically, and then Mr. W. F. Rigge has an article on 'Seeing the Lightning Strike.' Luckily it never strikes twice in the same spot.

Green Gold.

THIS does not refer to any one of the promoting activities of Col. W. C. Greene nor to the kind of precious metal that deceives the 'tenderfoot' in the West or the 'new chum' in Australia. Not long ago we read, in an Arizona paper, of a mine that produced a green variety of gold, which, on account of its color, brought a higher price than \$20.67 per ounce, the value of pure gold. We might have thought the incident merely one of the vagaries of the daily press had we not happened to know that there is an alloy of gold and silver that is green. Several years ago the present writer bought a nugget at Kanowna, in Western Australia; the gold of this nugget was of the usual reddish yellow color and it came from Siberia, a locality in Western Australia that gave a name to one of the disastrous 'rushes' of 1896. Subsequently, the gold was used for making a ring and the jeweler was told to add a little silver so that the metal might not be too soft. The resulting alloy had a distinctly green cast. Remembering this, and prompted by reading the story from Arizona, we wrote to Mr. Frank A. Leach, superintendent of the San Francisco Mint and recently appointed Director of the United States Mint. Mr. Leach sent a reply, which appears under 'Discussion' and which proves that gold and silver when melted in a certain proportion, and without the presence of copper, will give a green alloy. Of course, gold in thin plates is green by transmitted light; it is a vivid green. There does not appear to be any connection between the two phenomena

—for when we do not know what a thing is we call it a phenomenon. The green gold has a certain beauty of its own and it may become used in jewelry and the arts. Is it possible that the two metals when alloyed in a certain proportion cease to be a mixture and become a true compound, with qualities different from either component?

The Institute and Advertising.

ON ANOTHER PAGE will be found correspondence relating to the sale of advertising space in the Bulletin of the American Institute of Mining Engineers. It is not unkind to say that the inclusion of advertisements was a regrettable departure. It may have been necessary; we know of no obvious substitute able to make the money needed by the Institute. We do know, however, that the same question—of an increased income—came before the Institution of Mining and Metallurgy, at London, and the suggestion to sell advertising space was put aside without hesitation. It was deemed bad form. Concerning taste and colors it is useless to dispute, so that "bad form" is a kind of argument that stifles discussion. We do assume, however, that as the council of the Institute agreed to the placing of advertising in the Bulletin, it is not bad form in the eyes of men well qualified to judge. And yet to this we must add that the council of the Institution at London includes a large proportion of American mining engineers and that it is so constituted as to be international in character. Therefore the interposition of the Atlantic does not affect the different decision reached by the two councils. Of course, the financial condition that led to the taking of advertisements was due to Mr. Carnegie's gift. In that gift we never took any pleasure, because we consider Andrew Carnegie the first of the great rebaters, an unscrupulous financier, and the type of man who having amassed a colossal fortune by devious ways now poses as a providence to the unthinking. Most of his gifts have a string to them. *Timeo Danaos et dona ferentes*. The building of the United Engineering Societies is a sad example. Our Institute has obtained spacious quarters only to feel the pinch of poverty. When Mr. Carnegie gave the building, why did he not donate the ground also? It would have been a small matter. And now the Institute is saddled with a debt of \$180,000 (partly liquidated by subscriptions) and with increased expenses. How are these to be met? Wishing to be helpful, rather than merely critical, we venture to suggest that the dues of residents of New York and its immediate vicinity be increased, as they get the benefit of the new quarters, especially the library. There are about 400 members living in New York and its environs; whatever benefit the Institute may have got from Mr. Carnegie's gift, most of it has been theirs. To them the Building serves many purposes not within the reach of those that live at a distance; to them the library ought to be of great value, to the others it is of no use. To them is owing the acceptance of Mr. Carnegie's gift and to them we must look for a solution of the problem. We hope to receive some suggestions.

By the Way.

The record time made by the *Lusitania*, which made the Liverpool-New York passage in 5 days and 54 minutes, gives point to the following account of Atlantic travel, as published in the *Evening Post* of New York:

Time was once, and not so long ago either, when the 14-day boat excited the wonder, the admiration, and the general furore that the 4-day boat will excite next month, next year, or whenever it comes. One can imagine the mirth of the seamen along the British coast when, in June, 1819, a New York-built ship of prodigious ugliness, with a chimney amidships from which a dense volume of smoke was escaping, made up the Mersey. They thought she was on fire until Capt. Rogers, in answer to offers of assistance, explained that she was a steamboat. So she was, the first ever to cross the Atlantic under steam propulsion. She took 25 days to make the trip, 18 days steaming and 7 under sail alone.

Viewing the performance today it was nothing to speak of, but at the time it was better than the average time of the 'wind-jammers.' It was 19 years before another steam-driven vessel made the passage. For sail-powered packets were entirely satisfactory as the traveling and shipping world saw things then. Eighteen and twenty days were the quick passages of these packets.

In 1838, the *Sirius* and *Great Western*, two steamships, British built and British manned, crossed the ocean successfully. They were boats of 700 tons. They were of wood. Then came the record of the *Great Western* in 14 days.

The Cunard line was organized in 1840, appearing in the trans-Atlantic field with a quartet of wooden sidewheelers. The Yankee sail-packets beat these boats occasionally, but not often enough to defeat the object of the Cunard line in obtaining the best of the passenger and freight traffic. As an instance of the general build of the earliest Cunard liners, it might be pointed out that the *Britannia* was 207 ft. long, about the length of an average steam yacht, 32 ft. wide, 22 ft. deep, with tonnage of 1,155, and speed of 8½ knots an hour. With these boats the English line continued in the lead until in 1850, the ill fated *Collins* line, American to the backbone, was organized, building four vessels the size and magnificence of which were relatively far greater in comparison to the ships of contemporary lines than the *Lusitania* is today. There was the *Arctic*, 2,856 tons, *Atlantic*, 2,815 tons, *Baltic*, 2,723 tons, and the *Pacific*, 2,707 tons. They were driven by side-wheel side-lever engines of 800 hp. The American liners at once showed their superiority to the Cunarders so far as speed, at least, was concerned. The *Collins* boats cut the time to nine days and a few odd hours.

In the years 1854 and '55, the *Collins* line sustained losses of two of its crack vessels, the *Arctic* going down in collision with a French steamship, and the *Pacific*, leaving Liverpool for New York in January, 1856, steaming to an unknown bourne, whence never a splinter of her returned to tell the nature of the tragedy. From that time on Americans were never especially prominent in the fight to reduce the time across the ocean. The Cunard continued building new steamships, and in 1856 the *Persia* made a record of 9 days, 1 hr., whereupon people began to talk of the possibility of the eight-day boat. It came, 10 years later, in 1866, when the *Scotia* crossed in 8 days, 2 hr. The *City of Brussels*, three years later, crossed in 7 days, 22 hr. Of course these vessels were all of the screw type, the paddle-wheel boats going out for the most part in the early 'seventies. The *City of Berlin*, in 1875, pulled down the record to 7 days, 15 hr., and in 1876 and 1877 the *Britannia* and

Germanic, both of the White Star line, held the honors in turn, the *Germanic*, 7 days, 11 hr., and 37 min.; the *Britannia*, 7 days, 10 hr., 54 min. Then, in 1880, came the *Arizona*, of the Guion line, the first boat with watertight compartments. She crossed in 7 days, 7 hr., and 23 min. The *Alaska*, of the same line, established a record of 6 days, 18 hr., 37 min. in 1882. One can imagine the furore that made. In 1884 the *Oregon*, of the Cunard, crossed in 6 days, 11 hr., 9 min. All these records were made on the New York and Queenstown route, from Sandy Hook lightship to Roche's Point.

This company took a firmer grip on trans-Atlantic supremacy in 1885, when it brought out the famous *Etruria*. She lowered the record to 6 days, 4 hr., 43 min. But she held the blue ribbon only two years, another Cunarder, the *Umbria*, coming along and making the record 6 days, 4 hr., and 42 minutes.

It was an American line that first brought out the five-day boat, the *City of Paris*. It is true she was built in a British shipyard and sailed by British seamen under the flag of Great Britain, but at least American capital was responsible for her production. In any event, in 1889, the *City of Paris* crossed the ocean in 5 days, 19 hr., 18 min. Naturally the English merchant marine viewed this performance with envy, and the result was the production of the twin steamships, *Majestic* and *Teutonic*. The *Majestic* in 1891 shattered the *Paris's* record by just one hour and ten minutes. The *Teutonic* did not allow her sister to enjoy her honors for long, breaking the record herself in the same year—5 days, 16 hr., 31 min. In 1893, the *City of Paris* came into her own again, making the trans-Atlantic passage in 5 days, 15 hr., 58 minutes.

Again the Englishmen entered the lists, this time launching those two magnificent steamships, judging even from the standpoint of today, *Lucania* and *Campania*. In 1893, the *Campania* took the record away from the *City of Paris*, now the American liner *Philadelphia*, with a passage of 5 days, 12 hr., 7 min.

In the meantime, over the Southampton course, which is about 3,181 miles, whereas the Liverpool-Queenstown course is considerably shorter, 2,800 miles, the Hamburg-American liner *Fürst Bismarck* in 1891 made a record of 6 days, 14 hr., 15 min.

In 1900 the great Hamburg-American flyer *Deutschland* appeared. The product of the Vulcan Iron Works at Stettin, carrying with her all the hopes of German supremacy, she started from Plymouth for New York on her maiden voyage in July, 1900, and lowered the record to 5 days, 14 hr., 23 min. She made an average speed of 23 knots an hour over a course of 3,085 miles.

When the *Deutschland*, and before her the *Kaiser Wilhelm der Grosse*, captured the speed honors of the sea, British builders began the development of the cargo and passenger vessels of tremendous carrying, but of mediocre speed, capacity. As a result, one has but to glance at the *Baltic*, *Adriatic*, *Arabic*, *Cedric*, and other comparatively sluggish leviathans of the White Star line.

But in their hearts the British, as well as all the rest of the world, appreciated the full value of speed, as a war asset, if not a commercial necessity. And so, while the Germans waged their battle fiercely, while the shipbuilders of Stettin strained over the problem of drawing a fraction of a knot extra speed out of their reciprocating engines, the English turned their attention to the turbine. Inspired by the success of that little British warship *Turbinia*, marine engineers spent their days in experiments, until at last, under direct Governmental encouragement of the most substantial sort, the Cunard liners *Carmania* and *Caronia* were evolved.

They but led the way for the *Lusitania* and *Mauretania*, upon which boats the turbine system will stand.

Personal.

CURTIS H. LINDLEY is at Tonopah.

A. G. CHARLETON is in Switzerland.

G. SIMPSON PITCAIRN is in British Guiana.

E. A. H. TAYS has returned to Denver from Butte.

J. B. PITCHFORD has returned to Berkeley from Oregon.

H. C. HOOVER left London for Burma on September 18.

J. POWER HUTCHINS is expected in San Francisco from Alaska.

LOUIS C. RALSTON, of Berkeley, has taken offices in San Francisco.

JOHN A. REID is engaged in work for the U. S. Geological Survey.

H. S. DENNY, lately at Johannesburg, has been visiting the mines of Butte.

ALBERT ROBERTS has returned to Chicago after four months' work in Mexico.

PERCY ROLFE has been appointed manager of the Keystone mine, in Wyoming.

ARTHUR C. NAHL is on his way to Butte City, and from there he will go to Wardner, Idaho.

W. H. WILEY passed through San Francisco on his way from Los Angeles to Nevada and Idaho.

CHARLES F. NOURSE is proceeding from St. Petersburg to Kyshtim, in the Ural mountains, Russia.

JOHN D. IRVING is in Alaska. He has accepted the professorship of economic geology in Yale University.

HENRY F. LEFÈVRE is examining mines near Guadalajara, Mexico. He will be in New York by October 20.

FREDERICK S. HARRIS has retired from the management of the Kansas City-Goldfield Mining Co.'s properties at Goldfield, Nevada.

R. B. STANTON, who has spent the summer in charge of placer mining operations in Siskiyou county, California, is returning to New York.

R. B. WATSON and WILLIAM WATSON have formed a partnership under the name of Watson & Watson, with offices at 25 Broad St., New York.

R. M. ATWATER, JR., M. W. ATWATER, ROBERT LINTON, and R. DE SALLIER constitute the newly organized firm of Atwater, Linton & Atwater, at Helena, Montana.

THOMAS T. READ, professor of mining and metallurgy in the Colorado College, at Colorado Springs, has received an appointment as professor of metallurgy in the Imperial University of China, at Tientsin.

Obituary.

HENRY ASHE TILGHMAN, a native of California, died in San Francisco on September 10, at the age of thirty-five. He was a graduate of the Columbia School of Mines, class of 1893. He had held positions of importance, both as manager and consulting engineer, in South Africa, where he lived 12 years on the Rand and in Rhodesia. After January, 1907, he was resident manager of the Hot Creek Consolidated Mining Co. at Hot Creek, Nev. His health had been failing for some time. A skillful and conscientious engineer, a charming companion, and courteous gentleman, his death so early in life will be deeply regretted by his friends the world over. He leaves a widow and one son.

General Mining News.

ALASKA.

Boats are loading ore from the bins of the Omar, Rush & Brown, Mt. Andrew, and at Maple bay. The Alaska-Galena M. Co. will start shipping ore by pack-trains, pending the installation of an aerial tramway.—A hoisting engine has been erected on the Jessie claim of the Princeton M. & M. Co., near Dolomi. At the Valparaiso, owned by the same company, 25 men are working and taking out ore.—Electric drills have been installed and are working satisfactorily at the Jumbo mine of the Alaska Industrial Co. The mine produces about 2,500 tons per month.—There is a movement on foot to reorganize the Alaska Copper Co., and reopen the mine and smelter at Coppermount.—The cross-cut on the 300-ft. level, from the bottom of the shaft on the Niblack, is in good ore.

ARIZONA.

COCHISE COUNTY.

The management of the Copper Queen Co. has announced that it will not lay off any men, in spite of the decline in copper and the shaky condition of the market. This is good news for Bisbee.

GILA COUNTY.

N. H. Emmons, formerly chief engineer of the Old Dominion at Globe, has been appointed assistant manager for the Tennessee Copper Co., and will live at Copper Hill, Tennessee. H. L. Morton will be retained as chief engineer for the Old Dominion.

GRAHAM COUNTY.

The new furnace at the Shannon smelter did not get into operation as soon as expected, but will probably run during half of this month.—The Chase creek property, managed by I. N. Stevens, is said to be looking well.—A cross-cut is being run above the 200-ft. level to cut the gold vein on the Gold Belt D. & R. property. The shaft on the copper claim has been timbered and a hoist erected. First-class ore is hauled out over the wagon-road.—There is some activity in the Steeple Rock district, the nearest railroad station to which is Duncan.—Two shifts are working in the Oregon shaft of the Clifton G. & C. Co., which is being promoted by Louis Ferber.—About 50 miners have recently come to Clifton from the Copper King camp, and it is rumored that the New England company will close its mine, although it was recently announced that a new air-compressor had been ordered.

MOHAVE COUNTY.

Good copper ore has been struck 32 ft. down in the shaft of the Crow Canyon mines.—The shaft at the Treasure Hill mine is 140 ft. deep and drifts are being run on the ore. Several Missouri shareholders have recently visited the property.—P. R. Smith has arranged for the purchase of the Fairfield, Metallic Accident, and Keystone mines, in Mineral Park basin.—T. S. O'Brien will have charge of developing the Barney McCall properties in the Weaver district, for E. B. Van Deman.—The Victor power-plant at Needles will go into commission Oct. 1, and will supply 750 hp.—Will Cook of Virginia Camp has bonded his property to M. A. Moore.—Lessees have begun work on the Vanderbilt mine at Cerbat.—W. O. Young has organized a company in Salt Lake City, to take over the Kemple properties in the Weaver district.—The mill of the Stockton Hill M. Co. is making a good zinc and lead product. A 14-in. vein of clean lead ore has been opened in the raise from the 200-ft. level in the De la Fontaine mine.—A new electrostatic machine for separating zinc is being set up at the Tennessee mine.—J. F. Burkhardt is examining the Red Gap mine in the Weaver district.

YAVAPAI COUNTY.

(Special Correspondence).—On the 100-ft. level of the Redman mine, belonging to the Redman M., M. & S. Co., in the Willow Creek district, a 30-in. vein of sulphide ore has been uncovered, and in the 200-ft. level, 36 in. of ore of the same character has been struck in a drift. Samples

run about \$50 gold per ton. The shaft is down 270 ft., on a steeper incline than the ore-shoot, making it necessary to cross-cut to the pay-streak. Five veins will be developed from the shaft. Plans are under consideration for a mill, and the opening of the mine to a greater depth. T. E. Campbell has taken a force of miners to the Fuller group of mines on Squaw creek, to resume development on the property. The mines are the property of the White Horse Mining Co., and consist of eight claims and two mill-sites, all patented. One of the locations, which has been worked at intervals since 1878, has a record in gold production of \$100,000. The property is equipped with a 10-stamp mill and camp buildings for the accommodation of a large force of men. The claims are opened by a series of tunnels, the topography of the ground being favorable to this system of development. Squaw creek furnishes an ample water supply at all seasons. The camp is situated six miles east of Goddard and 25 miles from Cordes Sliding, the nearest railroad station on the Bradshaw Mtn. railroad.—At the camp of the Black Rock Mining Co., Ltd., in Black Rock district, the new mill is running and the results are satisfactory.—Work on the Hale property, in this district, is progressing in a satisfactory way with an excellent ore showing in the lower levels.

Phoenix, Sept. 14.

Sinking continues in the Boston-Jerome shaft, and the showing is improving.—A company has been organized to develop ground lying between the North Verde and the Arkansas & Arizona.—The power-plant at the Mazatzal mine is in operation, and development underground continues.—L. B. Adams of New York has undertaken to finance the Jerome Arizona Copper Co., owning a group of claims north of Jerome.—The Eureka tunnel is expected soon to cut the vein for which it is being driven.—Some pay-ore has been encountered in the Dillon tunnel of the Hull group.—Three shifts are at work in the Verde Grande, and the shaft is going down.

CALIFORNIA.

AMADOR COUNTY.

The Kennedy M. & M. Co. has had a survey made for a narrow-gauge railroad from the broad-gauge terminus at Martell to the mine, a distance of 300 ft. The company will lay the ties and steel on the road at once. The track will be about level, and the material will be lowered to the lumber yards at the mine by a stationary engine.

BUTTE COUNTY.

Los Angeles capitalists have purchased the Hazelton property on Feather river, two miles from Forbestown, and have incorporated it as the Pinal Butte G. & C. M. Co. The 10-stamp mill will be enlarged and the machine-shops rebuilt.—The Mammoth Channel G. M. Co. will operate extensively near Magalia. This company owns 1,580 acres. It has 8,500 ft. of old river bed on the Mammoth channel and 5,000 ft. on the Magalia channel. Operations began in the middle of June, and contracts have been let for a three-compartment shaft and a drainage tunnel. The shaft will be sunk 800 ft. and the tunnel driven 1,250 ft. long will intersect the shaft at the 510-ft. point.

NEVADA COUNTY.

It is believed that the Jenny Lind tunnel is now within about 200 ft. of the main gravel channel, and the long series of assessments may come to an end. The tunnel is in over 1,000 ft., and some think it will encounter the same rich gravel that the Godfrey people worked years ago.—The old Black Bear mine on Deer creek, several miles below Grass Valley and beyond Randolph Flat, is looking good. The owners, Fleishecker & Co., have bonded it to James English and the Eagen Bros., and a small crew of men is working. Three veins have been cut in the 300-ft. tunnel, and the bonders will start a cross-cut tunnel from the creek and strike the largest vein at a distance of 500 ft. from the portal. Some ore from this mine was milled years ago at Southern's, and some was shipped to the Selby smelter.—Two new suits have been filed against C. Christopher, to foreclose the mortgage on the Peabody mine.—State Mineralogist L. E. Aubury is in Grass Valley to inspect the

The old Hamilton mine is to be operated again. The mill will be overhauled, and the 10 stamps increased to 30. R. R. Kirk is in charge of the work.—Work is being pushed on the opening of the mine and mill of the Gold Dust M. & M. Co. There has been a good deal of delay in getting the last of the machinery.—A party of shareholders in the Senator company, operating near the head of Blue river, is visiting the property from Boston.—The Connessey property on the eastern slope of Baldy Mtn. will be worked again.—An enterprise is on foot to combine many of the large properties in the Montezuma district, establish a town in the middle of the district, and build a railroad from Kokomo. Six new

companies have been incorporated by George L. Nye, B. B. Morrison, and H. W. Wagner, with a view to effecting this consolidation. Chicago and Kansas City capital is interested in the enterprise.

(Special Correspondence).—The Delaware Gold M. & M. Co. expects to have its 50-ton concentrating plant ready to handle ore from the old Breen property in about 90 days. The mill, when completed, will contain Wilfley tables, Ding magnetic separators, two sets of 14 by 36 in. rolls, a King screen, a 9 by 16 in. Samson crusher, and a Wilfley furnace. Charles Loughridge is the manager.

Kokomo, Sept. 9.

TELLER COUNTY.

The Cresson Consolidated Co. continues to produce 2,000 tons of ore per month, and the ore is improving in value. Richard Roeloff, the superintendent, expects soon to be producing smelting ore.—The Findley Consolidated Co., on Bull hill, will resume work at once, the ore being handled at the 40-ton experimental mill of the Findley-Vindicator companies.—The Abe Lincoln lease on the Stratton estate, in Poverty gulch, comprising 10 blocks, has been sold by the Tunnel M. & D. Co. to the Colorado State Investment Co., of which John Sharpe is manager. Some

Henniger, of Elk City, have leased for two years the American Eagle mine. They will have the mine and mill running before winter, and employ 50 men. The American Eagle is now owned by E. O'Shea, of Spokane, and associates, who acquired it last February on a foreclosure. Several months ago the owners gave Mr. Brennan and his partner a short time lease on the mill and the ore dumps, and it is certain that the clean-up from the ore on the dumps must have been good, or they would not take a lease on the mine.—E. H. Dewey, of Spokane, principal owner of the Dewey mine and mill at Thunder Mountain, says the property, which is equipped with only a 10-stamp mill, has produced during the last four years a total of \$300,000. The camp is unusually active this summer. A long tunnel is being driven on the Fairview. The Sunnyside, which has been closed down since February, has resumed. Many of the miners are stopping work and scattering to the hills to prospect, and a labor shortage is threatened.

MISSOURI.

JASPER COUNTY.

The Columbia Zinc Co., with offices in Chicago, has recently been incorporated under the laws of the State of West Virginia with a capital of \$75,000, all of which, it is said, has been subscribed. The officers of this company are Geo. S. Rice, president, and T. L. Dee, treasurer. The mine is situated in the Joplin district and drills are said to have cut four distinct veins running from 12 to 18 ft. thick. It is reported that most of the stock is owned by those interested in the Sullivan Machinery Co., and employees of that company.

NEVADA.

ESMERALDA COUNTY.

(Special Correspondence).—At the Walker Lake mine, the shaft is down 85 ft. The vein carries a little copper, silver, and gold.—Good silver-lead ore has been found in the Nevada-Vermont.—Some gold and copper ore has been discovered in the Queen Regent group. Several quartz veins outcrop on the claims. With depth, the group will probably develop copper. The Queen Regent is owned principally by J. E. Kerr, of San Francisco.—Native copper has been found at the Copper Summit, being developed by Salt Lake parties.—At the Hunter-Murray group, ore carrying silver and lead has been found in small quantities.—A two-foot quartz vein has been found in the Rawhide. Six lessees are operating on the property. Adjoining claims are showing up well.—At the Regent much development is under way, and the mine is showing up well. Shafts are being sunk and tunnels and cross-cuts driven.—At the Steinheimer, good ore is being developed.—The Placers near Mount Grant are attracting considerable attention. Several strikes are reported, and a large number of prospectors are exploring the district.—A large body of siliceous copper ore is being developed in the Dunlap by the Tonopah M. Co. Some native copper is found in this property.—The Champion is shipping ore and is being developed. Goldfield people control the mine.—A Goldfield man has secured control of the Wonder, and is sinking a double-compartment shaft. Good ore is being developed.—At the Blue Light some low-grade and a little high-grade ore is being developed. Dan Storms is superintendent.—On the Vengeance group, two shafts are being sunk, and two gasoline hoists are in operation. Some ore is being developed. The group is controlled by Joseph Giroux, formerly manager of the United Verde, and now an operator at Ely.—At the Lost Confidence, a vein of copper ore is being developed. Ore running up to 10% is being sacked for shipment. The Big Strike, near Pitting, is showing well. It is being developed by Malcolm McDonald and associates.

Schurz, Sept. 12.

The mines of Goldfield produced 2,466 tons of ore during the week ending Sept. 14, with an estimated value of \$290,000. The shutdown at the Mohawk gave some of the bad ground a chance to cave, so operations will be hindered at that property until this ground is caught up. The output of the Little Florence has also been light. During the

A Part of Colorado.

new ore was recently opened on the 300-ft. level east of the shaft. The work was suspended for a short time on account of the destruction of the Golden Cycle mill.—The Trilby mine, situated on Bull hill, has resumed work after a short shut-down. Plans for the construction of a mill on the property are under consideration. The company is a Pennsylvania corporation, and L. K. Mearkle is president.—The lessees on the Modoc ground are shipping high-grade ore from above the 800-ft. level; on and below the 800 level the company is operating.

IDAHO.

IDAHO COUNTY.

A. F. Schultz, acting manager of the Del Rio M. & M. Co., announces that work will be resumed at once on the company's property at Buffalo Hump. The Del Rio was at one time one of the best known properties in the Hump district. In the upper workings more than 400 ft. of drifts and cross-cuts have been run, opening up an orebody running up to \$20 or more per ton. The lower tunnel, now in 600 ft., will be extended 2,000 ft. to get under the line showing exposed. A cargo of supplies is now being taken to the Hump for the Del Rio, including 500 ft. of air-pipe for ventilating the lower workings.—Patrick Brennan and John

week, the Nevada Goldfield Reduction works received ore as follows: Mohawk Combination, 418 tons; Little Florence, 120; Red Top, 316; Mohawk, 293; Higginson lease, 13; Hayes-Monnette dump, 29. Total, 1,189 tons. Total value about \$148,625. For the same week the Western Ore Purchasing Co. received ore as follows: Mohawk Jumbo, 664 tons; Florence Leasing & Mining, 110; Hayes-Monnette dump, 47; Little Florence, 66 tons. Total, 887 tons, having a value of about \$110,875. The Mohawk mine also shipped 130 tons of ore by rail.

The Jumbo Annex, a sub-lease of the Higginson, is reported to have struck some ore in a raise from the 176-ft. level.—The Pollard Florence lease continues development on the 300-ft. level.—The differences between the Little Florence and Florence Goldfield mining companies have been adjusted by the payment to the latter of \$177,800 for ore extracted beyond the lease lines, and the surrendering of the sub-lease on the Mohawk Florence.—The Daisy L. & M. Co. has struck a vein on the 250-ft. level.—At the

Map of the New Mining Districts of Nevada and California.

Mohawk Jumbo, a raise has been started on the vein cut 70 ft. east of the shaft on the 500-ft. level. The mine is producing about 100 tons of ore per day.

NYE COUNTY.

(Special Correspondence).—The Mayflower Consolidated Co. has reached the 400-ft. point in the main shaft and sinking is being continued. The management reports the vein cut at that level, and states that it still consists of a grade of good milling ore. The shaft is sunk on an incline of 65°. On the 100-ft. level, 90 ft. of lateral work was done; 325 ft. on the 200; 200 ft. on the 300 level, and 30 on the 400-ft. level. This mine is one of the best equipped in the district. A 12-drill, belt-driven, 100-hp. compressor was recently installed. Hoisting is done by means of a 25-hp. gasoline engine. The mine buildings are all substantial structures, including two large bunk-houses, boarding-house, assay office, and superintendent's office. Plans are under way for a 50-ton mill, the water for which will be piped from the Amargosa river, two miles distant, where the company has water-rights. The officers of the Mayflower-Bullfrog Consolidated M. Co. are: W. A. Stevens, president; John T. Overbury, treasurer; Chas. F. Ryan, and A. C. Eisen.—Adjoining the Mayflower is the Croesus, on which a shaft is being sunk to tap the Mayflower vein. At present writing the same has reached a depth of 310 ft. No lateral work will be done until the 500

level is reached.—In the same vicinity with the Mayflower is the Puritan, headed by a group of Boston capitalists. An 85-ft. tunnel revealed an orebody, 42 in. wide, carrying milling ore. The vein is well defined, both walls being disclosed, and an incline shaft is now being sunk on the foot-wall to tap the vein at a lower depth.—On Tobin Mtn., one mile northeast of the Mayflower, is the Pioneer. A 50-ft. tunnel has been driven and a winze sunk 35 ft. The company reports that they have some low-grade free-milling ore.

Rhyolite, Sept. 6.

(Special Correspondence).—The mill of the Montgomery-Shoshone Co., erected by the Traylor Engineering Co., and owned by the Bullfrog Reduction & Water Co., is nearing completion and will be turned over within two or three weeks. The course of the ore through the mill is briefly as follows: Reduced to 1½ in. size in crusher, then to an elevator and through the sampler. Then to a storage bin whence it is drawn to rolls crushing to ½ in. The product is then elevated to a double-screen trommel. Oversize back to rolls, the undersize to rolls, being screened on a 16-mesh centrifugal screen, undersize going to amalgamation plates and then to a Dorr classifier, sending the sand to five Wilfleys and the fine to 10 Frue vanners. The slime goes to dewatering tanks, to which is added the slime overflow from the Blaisdell collecting tanks, and then the thickened pulp goes to Blaisdell agitation vats. The sand is handled with a Blaisdell excavator, and the slime by a Butters filter. The plant is a complete one in every detail.

Rhyolite, Sept. 10.

Two shifts are at work sinking the new shaft on the West End, and the new 50-hp. hoist is working smoothly.—The shipments of ore from Tonopah during the week ending Sept. 12, over the Tonopah & Goldfield railroad, as reported by the Western Ore Purchasing Co., were as follows: Tonopah Mining Co. to smelter, 663 tons; to Virginia mill, 448 tons; to Desert mill, 2,800; Belmont, to Belmont mill, 1,390; Midway, to smelter, 202; Montana-Tonopah, to smelter, 36; Jim Butler, to smelter, 103. Total, 5,702 tons. Goldfield-Mohawk, 27 tons; the Kendall-Douglass of Manhattan, 11 tons.

OREGON.

BAKER COUNTY.

The smelter at Sumpter has closed down after a successful run. The furnaces could have been kept going longer if ore contracted for had been hauled from Susanville to Austin; proper fluxes were not on hand in sufficient quantity for a longer run. Good shipments were made from the Imperial and California.—The Worley mine in the Greenhorns has been examined by John J. Munzer, a mine operator from Pittsburg, for W. P. Killen and associates.—The Golden Chariot mine, operated by the Orleans G. M. Co., has been closed temporarily on account of lack of funds.—The new Present Need mill in the Quartzburg district is running.—Ray & Krouse have bonded a group of claims in New Eldorado to Eastern people.—The affairs of the Midway mine will be adjusted in the courts.—L. G. Lilley has received orders from Cincinnati to start work on the Last Chance property.—A contract has been let to run a raise from the lower tunnel to the upper workings of the Morning mine in the Greenhorns, by W. F. Butcher and Peter Basche.

SOUTH DAKOTA.

LAWRENCE COUNTY.

The Washington Consolidated ground in the Galena district has been examined by George Houston and J. T. Flint, and it is thought that the property will be purchased by a syndicate of Duluth men. The ore carries lead, zinc, and iron; the property consists of 80 acres, and has been opened by tunnels and shafts. The new owners will run a 700-ft. tunnel to cut several dikes, and will sink a 600-ft. winze at the breast. The same people are negotiating for the Richmond and Sitting Bull properties, which adjoin the Washington Consolidated.—The Branch Mint mill, near Galena, will be started before October 1. This plant will have a daily capacity of 800 tons, with 120 stamps and a slime plant. The ore is said to average \$4 per ton, and will be crushed in cyanide solution. This is

the largest cyanide mill in the Black Hills that crushes its ore in the same plant with the leaching apparatus. James D. Hardin is superintendent.—The Minnesota mill, near Garden City, with a capacity of 200 tons per day, will soon be running. The machinery is all on the ground, with the exception of the compressor and filter-press. F. E. Little of Minneapolis is the president.

PENNINGTON COUNTY.

The strike at the Jo Dollar mine, west of Keystone, and managed by G. A. Carr, is awakening interest in that district, where the Niagara, Deep Down, and Golden Slipper companies are also working.—The spodumene mine south of Keystone has made several shipments to New Jersey.—The water in the Holy Terror mine has been kept at No. 4 level with bailing skips, and the shaft is being re-limbered.—The new air-compressor for the Dorothy and Pettigrew tunnels will soon be in operation.—Thure Swanson has bonded his claims to Eastern parties.—The new steam-plant and air-compressor at the Mariposa mine on Slate creek, near Mystic, are in operation, and the main tunnel has been driven 650 ft. John Wise is the superintendent.—Work may be resumed at the Gertie tin mine at Hill City, under the direction of E. C. Johnson. A small quantity of tin from the mine was marketed last fall.—About eight men are employed in prospecting at the Gold Bug No. 1 claim, under Everest Palmer.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—At the Copper Key mine the cross-cut from the No. 2 adit has intersected the orebody for nearly 80 ft. The ore is changing from iron sulphide to quartz, which leads to the impression that the hanging wall is near.—Another vein has been cut in the new adit on the Oversight group. The ore carries smallite.—Several cars of ore from the Winnipeg mine are on the Belcher Mountain railway siding, awaiting shipment to the smelter.—The Belcher Mining Co. has brought suit in the Superior court of Ferry county against J. L. Harper, its former superintendent, to quiet title to the Hidden Treasure, Nazarine, and Nondescript claims, which adjoin the Belcher claim of this company.

Republic, Sept. 10.

BRITISH COLUMBIA.

Three furnaces at Le Roi smelter have started, after a shut-down of about a month. Fuel enough is available now for a rather long run. The Rossland mines produced as follows during the week ending September 7: Centre Star, 3,030 tons; Le Roi, 1,020; Le Roi No. 2, 350 tons of ore. Total, 4,400 tons.—The Idaho shaft is down 100 ft. and will be continued, to connect with a drift from the 400-ft. level of the Centre Star. A large tonnage of ore is being blocked out by development work in the Iron Mask, Centre Star, and War Eagle.—During the last few days, 70 men have been added to Le Roi force, and regular shipments to the Northport smelter will be resumed at once. Diamond-drilling continues on the Spitzee, and the development of the 1,650-ft. level is progressing.—Alexander Hill, consulting engineer for Le Roi No. 2, has been inspecting the property, and will examine the Vancouver mine, near Silverton, which the company is working.—No shipments were made from the White Bear during the week, but development continues.—A sawmill will be erected at the Inland Empire, to supply lumber for the new buildings and the 10-stamp mill that the company will build.—A small force of men is employed at the Jumbo.—Lessees continue to produce a little ore from the Nest Egg property.

During the week the Consolidated smelter at Trail received 4,818 tons of ore. In addition to the Rossland mines, the following contributed: Silver King, Nelson, 159 tons; Victoria, Nelson, 83; St. Eugene, Moyie, 170; Whitewater, Ainsworth, 161; North Star, East Kootenay, 133; Rambler-Cariboo, Slooan, 45; Standard, 26; Arlington, Slooan, 25; Queen, Salmo, 23; Arlington, Erie, 22 tons.—The Boundary shipments were as follows: To Granby smelter from Granby mines, 12,119 tons; from Emma, 440 tons. To B. C.

Copper Co.'s smelter from Mother Lode, 2,621 tons; from Snowshoe, 1,750; from Oro Denoro, 60 tons. To Dominion Copper Co.'s smelter from Brooklyn, 820 tons; from Idaho, 896; from Rawhide, 2,339; from Sunset, 875 tons. To Trail smelter from Snowshoe, 1,365; from Providence, 30 tons. Total ore shipments for week, 23,285 tons, and for year to date, 811,178 tons.—Boundary smelters treated this week as follows: Granby smelter, 11,559 tons; B. C. Copper Co.'s smelter, 6,635; Dominion Copper Co.'s smelter, 4,930 tons. Total for week, 23,124 tons. Total for year to date, 797,420 tons.

At a recent meeting in New York, of the shareholders of the Granby Consolidated, the regular quarterly dividend of 3% was declared on the outstanding shares of the company. There are 135,000 shares issued, at a par value of \$100 each, making this dividend amount to \$405,000. This makes a total of \$3,000,000 in dividends paid by the company.—E. N. Ouimette, of the Referendum Mining Co., reports that the quartz mill is now in operation at that property. In the recent discovery in Burnt basin, on the Yankee Boy group of claims, several open-cuts are being run on the vein.

MEXICO.

JALISCO.

A wagon-road will be built from the Pacific port of Las Peñas to the mining town of San Sebastian, where the Navidad M. & R. Co., managed by J. F. Buel, is operating. This company contracted to purchase the properties of the Jalisco Mining Co., for \$350,000, including a reduction plant and 13 mines. The Quiteria mine is being worked, and the others are being reopened. Air-drills will soon be in use, and a 200-ton cyanide plant will probably be built.—The 30-ton mill of the Ayutla Mining Co. will be in operation within a month. The crushing is done in a Blake crusher and two sets of rolls. The heaviest stockholders are A. W. Geist, A. H. Brewer, and E. G. Collman, and they also control the San Felipe, Vesuvio, and Zapatero mines.—The Real Alto M. Co., of Philadelphia, which was promoted by H. H. Cross, is employing 50 men in the San Sebastian district. The company owns the Peña Rejada, Las Cruces, and Santiago mines. H. W. Young is the superintendent.—The custom smelter of the Carrizo Copper Co. will be erected just north of the town of Ayutla. The company owns 40 acres.

SONORA.

The new furnace at the Verde Grande mine, 40 miles northwest from Hermosillo, will be blown in soon.—J. R. Hendra reports that he has a promising copper property 20 miles northeast from Alamos.—About 200 tons of graphite per month is mined at the Dewey mine, 16 miles southeast from Hermosillo. The product is sold in Pennsylvania.—The Quintera Mining Co. has struck silver-lead ore at a depth of 300 ft., at Minas Nuevas.—Seaman & Gustausson are developing cobalt ore in the Alamos district.—The Creston de Cobre Co. is developing a promising copper property 40 miles west of Hermosillo. The shaft is down 100 ft., 15 men are employed, and J. F. Wiles, of Los Angeles, is the general manager.—Work has been resumed and the mill is again running at the San Ricardo mine, near the San Miguel river, in the Ures district, north of Opodepe. Thomas F. Turner, of Canton, Ohio, is president of the company.—Charles Eddy reports finding a good prospect of gold and silver ore east of Alamos, and near the Chihuahua line.—A party of Los Angeles men is visiting the Eliza E. mine, 14 miles east of Alamos.—Peter Scott is developing a lead-silver property nine miles from Navajo, in the Alamos district.—L. H. Jensen, of Kansas City, is manager for the Llano Copper Co.—F. G. Forshaw is the superintendent of the Las Góteras mines, near La Barranea, in the San Javier district.—D. A. Moreno, of Santa Ana, will sell his Cerro Colorado mine in the Altar district to Pennsylvania capitalists.—Good progress is being made in the Santa Rosa mine, south of Douglas, which was taken over by the Caballona Development Co. The property was once owned by James Kirk, of Cananea, but was bonded by Thomas H. Collins. The old work consisted of a 260-ft. shaft, with a 50-ft. drift on the 200 level. Ed. McFarland is the superintendent.

Special Correspondence.

Johannesburg, Transvaal.

Output for July.—An Increase.—Details of Production.—Mining for Base Metals.—Diamond Syndicates.—The Chinese Labor Problem.—Local Manufacture of Cyanide.

The returns for July, which have just been published, show that the industry has returned to the pre-strike basis. The total output for the Transvaal in July was 532,711 oz. valued at £2,262,813, of which the Rand contributed 513,655 oz., valued at £2,181,867. The output of gold from the Rand shows an increase over June of 25,699 oz. During July there were 8,580 stamps at work in the Transvaal, of which 8,220 were crushing on the Rand. To show the value of the July output relative to the other months of this year, the following table is given:

January, 1907	537,638 oz. valued at £2,283,741
February "	493,542 " " " 2,096,434
March "	538,497 " " " 2,287,391
April "	537,019 " " " 2,281,110
May "	524,477 " " " 2,227,838
June "	507,599 " " " 2,155,976
July "	532,711 " " " 2,262,813

As usual, the Robinson mine was the premier producer in July, with an output of 22,814 oz. valued at £96,908, while the Simmer & Jack was second with an output of 22,435 oz. valued at £95,298. During the strike many of the mines sorted out much less waste rock than usual, in order to keep the mills at work, but in July the amount of waste rock discarded was normal again.

The Luipaard's Vlei Estate mine shows far and away the highest crushing duty per stamp per 24 hours, namely 8.5 tons, while the lowest recorded duty was that of the Windsor mine with 3.56 tons per 24 hours. Quite a number of mines show a duty of seven tons and over. Tube-mills are responsible for this high stamp duty. As regards labor, the figures show that during July there were 7,592 natives recruited, while 8,146 Kaffirs left the Rand. The Chinese figures show that the total laborers in South Africa available for mines on July 31, 1907, were 51,441.

It is of interest to note that the Messina Copper Co. declared an output of 150 tons of copper glance in July, assaying 60.49% metallic copper. A prospect called Campbell's Mercury made a rather encouraging report as regards mercury. Several parties are doing some work, in a small way, on silver-lead properties. Altogether quite a lot of quiet work is being done in the Transvaal on the base metals.

Diamond syndicates are as popular in these hard times as ever. In fact, the only way to raise any money just now is to get up a diamond syndicate. It does not matter much where it is situated, at the centre of the earth, or on the moon, just so long as the magic word 'diamond' appears. Men who have only £100 or so left in the world, would not dream of placing it in a sound business investment, where they can obtain 5% interest, but they will put every penny of it in a diamond syndicate in the vain hope that their money will increase ten fold.

There has been a plethora of rumors on the Rand during the past fortnight, on the subject of the fate of Chinese labor. One day we are told that the coolies must go, and the next that the Government is so worried over the scarcity of native labor that they will allow the coolies to remain. There seems to be little doubt that the Botha ministry are at their wits' ends in regard to the labor problem. Probably they themselves do not know for

certain what will be the outcome. The Boers are opportunists, and at the last moment, they would readily take the line of least resistance, and give the order "right about, turn" as regards the Chinese question. According to the constitution, the present Chinese ordinance becomes null and void next March. At that date, unless new legislation supervenes, every Chinaman on the Rand will be free to do as he pleases. But the Government has hurriedly brought in a bill to allow the coolies whose contracts remain unfinished next March to work out their indentures. This means that the last Chinaman will not leave the Transvaal before 1910. The chances are that the 17,000 coolies due to leave the Rand this year will go. What will happen next year, no one knows. One of the greatest opponents of Chinese labor is J. B. Robinson, controller of the Randfontein group of mines. This month nearly 2,000 coolies employed on one of his mines are due to leave the Rand. To the surprise of every one, this anti-Chinese champion has anxiously inquired if his coolies can sign on for three years more, and has sent in a pleading petition from the Chinamen, asking leave to remain at work in the Transvaal. This is a sample of the double-faced way in which the campaign against the Chinese has been carried on.

Considerable interest was excited last week by the

Map of South Africa.

announcement in the daily press that a company, the South African Cyanide Co., Ltd., had been formed with a capital of £50,000 for the purpose of manufacturing sodium, potassium, and magnesium cyanide, as well as soda crystals, bi-carbonate of soda, and other products, all of which are at present imported into the colony. Contracts have already been entered into for the supply of 80% of the cyanide used in the Transvaal, subject, of course, to the condition that the article be up to the standard of the imported chemical. At the present time Germany supplies almost all of the cyanide used on the Rand. The German article is subject to a duty of 3%, while the British article is allowed in free. The price of potassium cyanide delivered on the Rand is about £70 per ton, and of sodium cyanide about £90 to £100 per ton. The monthly consumption of cyanide is about 400 tons per month. It is to be hoped that something will come of the new enterprise, and that it will not go under, as so many industrial enterprises have done in this country. The press has given the South African Cyanide Co. a fine puff, for like everyone else, they want to see industries started in this country. Whether the chemicals made by the new company can compete with the excellent stuff sent here from Germany remains to be seen.

Denver, Colorado.

American Mining Congress.—A Lucky Landslide.—New Cyanide Mills. Durango Smelter.—Telluride Ores.

The American Mining Congress seems to be thoroughly imbued with the prospector's spirit. Its old men see visions and its young men dream dreams. Among the latter is the proposal to get from Federal sources the funds to construct a "million dollar mining temple" in Denver. In the temple there is to be a staff as nearly like that of an agricultural experiment station as the nature of the two industries permits. That such an institution could have any value commensurate with the expense of its maintenance appears extremely doubtful. Indeed the projects of the Mining Congress generally seem to be tinged more with rosy optimism than with common sense. One of its pet projects is to secure the creation of a Department of Mining in the Cabinet at Washington, on the basis that as mining and agriculture are the two fundamental industries, therefore there should be a department of mining as well as of agriculture. How absurd this appears when we reflect that the value of the annual production of such an inconspicuous thing as hen's eggs alone exceeds the annual production of any single metal, excepting iron and gold, and several single crops each exceed in value the total annual production of all metals combined. It is not minimizing the value of the mining industry to say this, but simply regarding relative values in a sane way.

Some men are born rich, some acquire riches, and others have riches thrust upon them. A case in point occurred the other day between Leadville and Breckenridge, where some people have for a time been prosecuting development work on a claim near the top of Mount Sheridan, but without any marked success. The other day a landslide occurred near their workings, leaving exposed a vein six feet wide that is reported to assay \$150 per ton. Now if some inventive genius will only devise a method of producing landslides at will, a cheap and convenient method of prospecting will be available for everyone.—The Yak Tunnel has secured a second shaft connection by the breaking through of the M. N. shaft to the tunnel level. The Yak is also engaged in developing near-by properties that do not connect with the tunnel-level.

The number of cyanide mills under construction or proposed in the Cripple Creek district increases daily. The latest is a mill of 100 tons per day capacity to be built at the mouth of the Good Will tunnel, near the edge of the town.

Considerable quantities of oxidized ore are exposed in the tunnel, and it is for the treatment of these that the plant is to be erected. That part of the Golden Cycle mill that was not destroyed by the fire is now engaged in treating the material accumulated on the tailing dump of the old Telluride company. Judging from the rate at which the work of reconstruction is progressing, the plant will not be immediately rebuilt. The Portland and Standard mills are running full capacity, and are treating the larger part of the tonnage formerly handled by the Golden Cycle.

Rumors are afloat that the capacity of the Durango plant of the A. S. & R. Co. is to be largely increased. The present equipment of roasters and kettles for the H. & H. process is to be nearly doubled, and possibly another blast-furnace may be added. The smelter of the Ross Mining & Milling Co., at Silverton, which apparently had been conducting a successful campaign, has closed for the present, and no definite announcement is made as to reopening. A prominent shipper to the Durango plant is the newly-developed May Day, near Hesperus, which while contributing ore to the smelter also contributes not

a little to its problems; for the ore consists of tellurides of gold and silver in a gangue of quartz and a highly aluminous clay that is not at all easy to flux. Cripple Creek is generally thought of as the only place in this country where tellurides are of much importance, but when one stops to count them up, the number of mines throughout the State where the gold and silver are contained in tellurides is surprisingly large.

Butte, Montana.

Effect of Copper Decline.—Curtailling the Output.—Exaggerated Rumors.—Remarks of John Gillie.—North Butte Discovery.—Important Development.

The Amalgamated and associated mining companies have no present intention to shut down their mines, notwithstanding a report to the contrary from New York and Boston, but a policy of curtailment and retrenchment, inaugurated several weeks ago, is being carried out, and the September output of copper will show a diminution of fully 40%. That policy is to be continued

Montana.

until the curtailment amounts to at least 60% of the normal production. The purpose is, as is well known, to avoid a great storage of copper and keep down the production until the consumption of the metal catches up with the output. The curtailment during the past month has not, however, been due entirely to the copper situation, the strike of machinists in Butte having been in part responsible, the strike necessitating the closing of some of the mines.

The policy of retrenchment is not confined to the Amalgamated, but will be followed by other mining companies in Butte, including the North Butte, Coalition, and Pittsburg & Montana. While the curtailment of the copper production of these companies will amount for the present to fully 60%, the force of miners will not be reduced to the same degree, as the fixed crews at the different mines will have to be retained whether the production is 10 or 90%. However, there will be a decided reduction in the working force at all of the mines, and many men are being laid off. In addition to the general reduction of the working forces, mining will be entirely suspended on Sundays, and all construction work at the mines and smelters will be stopped. Extensive development work and shaft-sinking will cease, with the exception of the sinking at the Badger State and Greenleaf mines of the Boston & Montana Co. Work on the new head-frame at the Pennsylvania mine will continue, but the work on the ore-bins at the Penn-

sylvania, West Gray Rock, and Buffalo has been ordered suspended. At the Belmont mine the work of enlarging and re-timbering the shaft has been stopped, and operating expenses will be cut wherever possible, but every effort will be made to avert the necessity of a general shut-down.

The normal production of the Amalgamated companies is about 20,000,000 lb. copper per month, but this will be reduced to at least 7,000,000 or 8,000,000 lb. This curtailment is being brought about gradually, but has been going on for several weeks. The orders for the suspension of Sunday work, as well as construction and development, have been given by the general superintendent, Mr. John Gillie. The main reason for it is the gradual accumulation of copper and the absence of adequate buying by manufacturers. It is considered poor management to mine copper and store it, without even the present prospects of getting mining costs out of it. Notwithstanding the fact that consumers have not a large supply of metal on hand they are not buying copper, except in quantities sufficient to meet requirements from week to week. They must have knowledge of the fact that the producers are accumulating the metal, and are satisfied to have it accumulate in the hands of the producers rather than on their own while the price of the metal is so uncertain.

"Conditions are unnatural," said Mr. Gillie in discussing the situation. "Manufacturers are running their plants just as usual, and the whole country is prosperous. The railroads are doing 40% more business than they did a year ago. The iron and steel business is good, and the farmers certainly are prosperous. The only complaint the farmers have is that they cannot get men enough to harvest their crops. Conditions in the copper business must improve, but when the change will come no one can predict. Consumers evidently do not believe that the bottom has yet been reached, and they are buying metal only in small lots. When they are satisfied that the bottom has been reached they will buy in 10,000,000 lb. lots instead of 100,000 lb. lots, as they are doing now. But in the meanwhile the producers have their money tied up in the surplus stock, and a curtailment of production has become necessary." Mr. Gillie added that the only advantage to Butte that would come out of the curtailment would be a relief to the fuel situation, as it would probably avert a coal famine. The companies will, of course, use a correspondingly less amount of coal, which will be diverted to the commercial trade.

One day last week when North Butte copper shares sold at \$48, and stockholders thought the bottom had been reached, a report came from the mines of the company of an important development, the discovery of a big and exceedingly rich orebody, the announcement of which under ordinary conditions would have sent North Butte stock skyward. The new orebody developed is in the west drift of the Edith May on the 1,800-ft. level. The drift has been extended 500 ft. west from the cross-cut and for 200 ft. the ore has been especially good, improving with every foot of advancement. In the face of the drift the orebody is 26 ft. wide, and assays give an average of 12% copper for the entire width. The ore is glance and bornite. The orebody is much larger and better than it is vertically overhead on the 1,600, and better than the manager, A. C. Carson, had expected to find. The west 1,600 drift is about 400 ft. further ahead than the drift on the 1,800 and the ore has been improving as the drift has progressed westward. If the same condition is found on the 1,800, as promises to be the case, the vein at that depth is likely to develop into a bonanza. The company is also driving the 1,800 cross-cut for the Jessie vein, lying north of the Edith May, and the opening is now

about 150 ft. beyond the Edith May vein. Early in October sinking will be resumed on the main shaft, which is now 1,900 ft. deep, and 200 ft. will be added. At 2,000 ft. stations will be cut and the veins then explored at that depth. It is expected that the addition to the shaft and the stations will be completed by the first of the year.

Deadwood, South Dakota.

New Mills Started.—Mica Mining at Custer.—The Victoria Co.—Repairing the Homestake Shafts.—Renovating Old Mills.—The Branch Mint.—Theft of Precipitate.

Within the next ten days it is expected that the new mill of the Saginaw Gold Mining Co., at Custer, will be placed in commission. This is a mill constructed along new lines and is a decided departure from the ordinary Black Hills practice, and for that reason its operation will be closely watched. The ore is a typical quartz, carrying gold in a free state and in pyrite. After the usual preliminary crushing in rock-breakers the ore will be reduced in McCullough pulverizers, a machine constructed similar to the ordinary rolls, but differing from them in that the side of the shell, rather than the face, is used in crushing. The sides or crushing faces are trimmed off at an angle of about 30° from the side of the shell. A different speed is maintained on each so-called disc, and by this means a combined crushing and pulverizing action is secured. Among the important claims made for this machine is that the shells wear smoothly and absolutely free from corrugations. Peculiar boxes are used to take care of the end-thrust, and high crushing duty is claimed. I. W. Herber is president and manager.—The Ivanhoe Gold Mining Co., also at Custer, has authorized the construction of an up-to-date amalgamation and cyanide plant; work has already started on the foundations. The company has done a large amount of development, opening orebodies that fully warrant the mill equipment, and has thoroughly tested the ore in a small mill, which has been in operation intermittently for nearly two years. H. F. Ratte is manager.

The mica mining industry of Custer has received an impetus within the past year through the purchase, by the Westinghouse Electric & Mfg. Co., of several groups of claims. One of these, the New York, has been equipped with machinery and a steady production is being maintained. Twenty to 30 miners are employed. The mica is hauled to Custer from the mine, and there sorted and prepared for shipment by girls and young women. About 50 operatives are here employed. The company has been continually adding to its property holdings and only recently made a \$5,000 purchase from McGonigal & Beatty.

The Victoria company, in the Ragged Top district, near Deadwood, has recently started its new mill, and is rapidly bringing the plant up to the maximum tonnage—250 tons daily. The ore, which is an altered and mineralized Carboniferous limestone, is treated by the dry-crushing cyanide process. Under the management of F. E. Steele, a graduate of the South Dakota School of Mines, a good recovery and most satisfactory results are being obtained. The ore averages a little better than \$4 per ton. The Victoria-Extension, owned and managed by practically the same parties, is shipping smelting ore from the Ulster claim.—The Echo Gold Mining Co. is putting in a plant of electrically driven machinery and will shortly begin deep mining. This company owns an acreage in the Maitland district, four miles from Deadwood, and has confined itself to tunnel work in the past. The plans now include sinking a deep shaft to exploit the

veins opened near the surface, from several of which gratifying assays have been returned.

The repairing of the damage caused by the fire at the Homestake is well in hand, with a large force of men. Workmen are now employed on the pumps on the 1,100-ft. level of the Ellison, overhauling them and cleaning up the rubbish that accumulated from the flooding. Within a few days the pumps will be in running order and then short work will be made of dewatering the remaining 450 ft. of this shaft. Stopes and workings on these lower levels are not as extensive as above, and it may be said that the mine is about four-fifths unwatered. The Star shaft, the nearest opening to the region damaged by fire, was injured by caves and thrown considerably out of line. After six weeks of work this damage has now been fully repaired, and a crew is employed straightening and level-

on the outskirts of Deadwood, was found a gasoline furnace and complete rig for turning the precipitate into marketable bullion. Detectives are now at work and it is probable that further startling disclosures concerning this and other plants will be made in the near future.

Toronto, Canada.

The Crow's Nest Coalfield and the Granby Copper Co.—The Guggenheim's Concession.—Ore Shipments From Cobalt.—New Discoveries.—Strikers in Court.

Reports having been circulated respecting the securing by J. J. Hill, the Great Northern Railroad magnate, of a controlling interest in the Crow's Nest Pass Coal Co. by the purchase of large holdings of Toronto shareholders, and Robert Jaffray, a vice-president, has given out a specific statement of the relations of Mr. Hill and the company, characterizing the current reports as untrue. While denying that Mr. Hill has secured a controlling interest, or bought out Toronto stockholders, he states that the Granby Copper Co. of Grand Forks, B. C., which is naturally interested in the Crow's Nest Pass operations, as it is the largest consumer of coke in the Province, has recently purchased a large block of Crow's Nest stock, paying for it about \$700,000. The Granby Co. and Mr. Hill have in addition put a good deal of money into the treasury of the Crow's Nest Co. for the enlargement of its operations. The present output is about 3,500 tons of coal per day, and with the additional capital secured it is intended to increase the output as soon as possible to 7,000 tons daily and ultimately to 10,000 tons. As soon as the Granby Copper Co. can rely on a daily supply of 1,200 tons of coke, equivalent to 2,000 tons of coal, they will double their capacity for the treatment of ore. There has been no question of control and there is no feud between parties in the Crow's Nest Pass directorate. Manager Lindsey retains his position with the full confidence of the board and of Mr. Hill.

A committee has been appointed by the Yukon Territory legislature to memorialize the Canadian Government regarding the Boyle concession in the Klondike camp; this covers 40 square miles and is partly owned by the Guggenheims. An investigation as to how the concession was acquired and the terms on which it is held is asked for.—A party of about sixteen English journalists representing leading daily and financial newspapers has arrived in Ontario, on the invitation of the Government, to inspect the mineral resources of the Province. They will leave Toronto on the 16th and visit all the important mining centres of northern Ontario.

Shipments of Cobalt ore for the week ending September 7 amounted to 162 tons from the following companies: Buffalo, 30; Coniagas, 125; La Rose, 40; and Nova Scotia, 30 tons. Men engaged in grading on the Kerr Lake branch of the Temiskaming & Northern Ontario Railway unearthed a cobalt vein yielding from 800 to 1,000 oz. per ton of silver on the Kerr Lake or Jacobs property. A cobalt vein 4 ft. wide has been found at the Temiskaming & Hudson Bay mine. It will be tapped by cross-cutting from the main shaft, which is now down 80 ft. Two 80-hp. boilers and a 16-drill compressor are being installed. The Ruby Silver Mining Co., in Bucke township, has installed a small steam plant and drill. The main shaft is down 40 ft. on four veins, all of which show good silver contents. Willet G. Miller, Provincial Geologist, who has been inspecting some of the newer finds, states that most of the discoveries in James township are in diabase. At Silver lake, five miles west of Bear creek, on Montreal river, native

A Part of Ontario, Canada.

ing up the shaft-house. The Homestake has commenced the rebuilding and renovation of its older mills, those which have been in continuous operation for 25 years or more. Old mortar-blocks, battery-posts, etc., that have withstood wear for a quarter of a century, are being replaced with new timbers. The work is being undertaken in a leisurely way, ten stamps being hung up at a time.

E. M. Hilton is in the Lawrence county jail at Deadwood, charged with the theft of precipitate from the zinc-boxes of the Golden Reward Co. After his arrest Hilton broke down and made a full confession, acknowledging his guilt and implicating F. L. Thorpe, a Lead City jeweler as the purchaser of the gold. Thorpe was arrested but released on \$1,000 bonds. Hilton had been systematically stealing from the zinc-boxes, and at his house,

silver has been found and many claims staked. One vein near Silver lake was 7 in. wide with the silver well distributed.

The Cobalt strike promoters are now before the courts, their prosecution for the infringement of the Industrial Disputes Investigation Act having been undertaken by the Provincial Government. Under the provision of this act, passed a few months ago, striking is illegal in connection with the mining industry, unless a Government investigation of the dispute has first been held. James McGuire, president of the Cobalt Miners' Union, affiliated with the Western Federation of Miners, was found guilty by a local magistrate and fined \$500 and costs or two months in jail. An appeal was taken and McGuire was released on bail.

Mexico City.

Heinze and El Potosi.—Rumors of a Sale.—Important, if True.—Old Days in Santa Eulalia.

Persistent rumors come from Chihuahua to the effect that F. Augustus Heinze is after the El Potosi mine, in the Santa Eulalia district and near the city of Chihuahua, but that he is waiting the decision of the Mexican Supreme Court on the Dolores case, which was mentioned in the columns of the MINING AND SCIENTIFIC PRESS a few weeks ago, before he acquires larger interests in that part. The El Potosi Mining Co. is a subsidiary company of the Chihuahua Mining Co., which is controlled by Grant B. Schley, of Moore & Schley, Dennis Sullivan, and others closely allied to the Standard Oil Co. The names, therefore of the principal stockholders makes such a deal as reported seem most improbable, though it is true that E. H. Wilson, of Butte, and W. Zeigler, J. W. Kingsbury, and E. M. Norris, of Salt Lake City, have just left Santa Eulalia after several weeks spent in a general examination. The Potosi is reported by many to be the greatest silver-lead mine in the world and over 1,000,000 tons of high-grade ore are supposed to be blocked out. The negotiations are said to include the properties of the Chihuahua Mining Co. in Santa Eulalia, and the figures are in the neighborhood of \$100,000,000. But, as stated above, it is most improbable that Mr. Heinze will invest more capital in Santa Eulalia or elsewhere in the Republic until he learns of the interpretation of Mexican justice to be rendered in the Dolores case, which is being fought by his representative, J. P. Hutchinson. The interests that control the Chihuahua Mining Co. are practically identical with those controlling the Chihuahua & Pacific Railroad (which will probably eventually become part of the Kansas City, Mexico, & Orient system) and the Calera Mining Co. at Miñaca, which is said to be the largest zinc mine in the world. C. M. Pringle is in charge of the latter property and has just completed the installation of a Sutton-Steele dry table, and the plant will be further increased if it continues to be successful.

C. R. Hughes, manager for the Sacrificio Mines Co., twenty miles from Nombre de Dios in the State of Durango, is quoted as saying that a deal has been carried through by Alpine & Williams for the sale of the Verde mines in the Parilla district to New York people for \$120,000. He states further that the old Vacas mines in the same district are soon to resume operations. These mines, though having good bodies of disseminated galena ore, a well equipped concentrating plant with the old southeast Missouri jigs and a three-stack smelting plant, have done very little since the spring of 1895, when Wm. J. Grace and his mother, of Rochester, New York, appeared upon the scene and in some way acquired control of the property, with the result that it has been in

litigation ever since. Within the last five years the mines were examined by Walter S. Kelley, and it was thought they were to be started up, and even more recently B. Clark Wheeler was supposed to have obtained a lease and bond on the property, but always there seemed to be some hitch. Certainly it is to be hoped that matters have at last been straightened out and that there will soon again be the activity of 12 or 15 years ago. But there will not now be the same excitement in disposing of the product as there was then, when the lead bullion was refined in a Mexican *vaso* (or cupel furnace) and the resulting silver buried until there was sufficient for shipment, when superintendent Brittan, without advising anyone, would skip out in his two-wheeled cart, made especially heavy with an iron compartment under the seat, with a heavy guard, and by leaving early in the morning at or before daylight, so as not to be seen, Durango could be reached before night. This was made necessary by reason of the region through which they had to pass, the little settlement of La Parilla being famous as a rendezvous for the most noted bandits in the State of Durango, and more than one cross used to stand along the road between Vacas and Durango to mark the spots where guard or attacking party had been picked off. But repeated Government raids on La Parilla cleaned out that place and it is now a peaceful little town, so that only a long stretch of lava flow about midway between Vacas and Durango gives one the right in the present day to speak of the trip as one through the 'bad lands.'

Morenci, Arizona.

Arizona Copper Co.—Mining in the Carlisle District.—The Lone Star District.—Good Work at the Shannon.—Talk of Consolidation.—Accidents on Inclines.—Patagonia.—The San Carlos Strip.—Old Discoveries Revived.

The output of the Arizona Copper Co. for the past month shows a decrease from the usual average, being but 1,177 tons of converter copper. The shortage, however, was caused by the strike of the smeltermen early in the month, and by the heavy rains that came later, filling the flume with mud and debris, thereby cutting off the water supply. However, it is stated that everything is in good order and the usual amount of copper is being made. Some good ore is being shipped to the Shannon smelter by F. H. Perry, of the Carlisle district.—Pat Crowley, one of the old-time prospectors of this district, in company with Dan Fraser, has gone on a tour of inspection of the new Carlisle district. He has been interested in many of the mines, one of them being the Antietam, now belonging to the New England Co.

The New York-Arizona Gold & Copper Co. has been strengthened by the appointment of Charles Alleu as general manager. This company was recently organized to take over the Home Copper Co. properties, lying six miles northeast of Morenci. The property consists of the Buzzard's Shadow, the Lillian, and six other good claims, bounded on one side by the Gold Belt Development Co., and on the other by the Detroit Copper Mining Co. The Gold Belt people have moved their general offices and post-office address from Clifton to Morenci. There has been talk of the consolidation of the Arizona Copper Co. and the Shannon Copper Co, but this is not confirmed. In fact, everything points to the contrary. The Shannon for last month put out a little over 600 tons of converter copper, the plant being closed down six days for construction and repairs. The Minneapolis Steel & Machinery Co. has finished its contract with the Shannon people and is now engaged in finishing the machine-

shop at the Detroit concentrator at Morenci. The Shannon company has been averaging about 600 tons of converter copper per month, but in the near future an increase in operations and output will be made. The large new furnace is about completed, and this will take the excess ore supply that has been a cause of trouble in the past months. Old-timers in the district remember that the Shannon started when the price of copper was low, and that, with other troubles and obstructions, would have caused most ordinary properties to fail. Its real advancement did not commence until the present management (with J. W. Bennie as president-manager) took hold. Since Mr. Bennie's advent a smelter, concentrator, and many other necessary improvements have been added, and now the company has a smooth road ahead, with three 50-cent dividends already to its credit. Many of the smaller companies in this region are dependent upon the Shannon for the treatment of their ore.

The last month has witnessed two fatal accidents on inclines, one on the Shannon, the other on the Longfellow incline of the Arizona Copper Co. Both were caused by the breaking of the cable, and five men in all were killed, with two seriously injured, all being Mexican miners and timbermen.—Water in the Arizona Central mine is causing trouble to the Detroit Copper Co. This is the only mine of this company that is not entirely dry.—A meeting of the Arizona Gold Mines & Milling Co. has just been held, new officers elected, and arrangements perfected for further development. Frank Falke, of Fort Wayne, Ind., was re-elected president; Walter Lloyd, of Lincoln, Neb., vice-president; and J. J. Wyatt, secretary and manager. The property consists of a group of gold claims in the Patagonia district; a 5-stamp mill has been in successful operation for several months. This mill is to be increased to 15 stamps, the 1,000 ft. of development work showing sufficient pay-dirt to warrant the addition. The property is already equipped with pumps, engines, and buildings. The Dragoon holdings of this company embrace the Ryder and Swayzee gold group at South Pass. Several good lodes have been opened in these workings, and ore shipments have given satisfactory returns. The main shaft is down 125 ft., and it is the intention of the management to rush the work at this point.

A mining district in which a large number of Safford and Globe people are interested is that embraced in what is known as the San Carlos strip. About ten years ago, after repeated appeals from mining men, the Government opened to entry a large part of the San Carlos Indian reservation lying south and east of the Gila river. Later, another tract has been thrown open and many locations made. As a mineral area the strip has not been found wanting, but capital has been forthcoming. After ten years of exploitation in a desultory manner, the field is still unexplored. The earliest operations in prospecting met with adversities that few soldiers of fortune dared to face, and many who dared lost their lives in the undertaking. In 1892 two Germans, Jake Filleman and Fred Haas ran cattle in the Santa Teresa mountains on the east end of what is now the strip. Their log cabin still stands. It was known as the Dutch cabin for many years, and today it is surrounded by many cabins and tents that have become a part of the new Cobre Grande copper camp.

Filleman and Haas, during their cattle operations in these mountains, located a copper claim and sunk a shaft, but they were not altogether successful in their enterprise, either in developing ore or attracting the attention of mining men to the district. It became known as the Boeken shaft and no work was done in it for many years until last year, when Julius Riser, a Globe prospector, went into the district and discovered rich ore all along one side of the butte. Today there is an excellent prospect, and the old Boeken shaft is embraced in the group of claims known as the Cobre Grande. A. T. Hammans and A. G. Smith are the owners of this property. It is situated on the extreme west end of the porphyry zone in which the mineral is found. There are also a number of other claims. Close to Stanley Butte there is a group of claims that possess interest for the reason that their prod-

Map of Arizona.

uct of copper years ago assisted Dr. Flower, promoter of the gigantic fraud known as the Spenazuma swindle, in selling a million dollars of stock in his notorious Black Rock project. This group was then known as the Annie Rooney, and Dr. Flower sang her praises under the signature of 'Spenazuma.' The ore from this and other claims was packed to the Spenazuma workings and placed on the dumps to delight and allure the Eastern people who came to see the mine. The Annie Rooney is now one of the Cobre Verde group, owned by the San Carlos Development Co., whose directorate contains the names of many Globe men. W. C. Duncan is the general manager. The ore is found in the porphyry zone that traverses the district. The first shaft sunk follows the ore to a depth of 43 ft. The vein continues strong with a width of 3½ ft. The second shaft was sunk about 25 ft. east on a second vein and has reached a depth of 82 ft., and a cross-cut is being driven to determine the width of the ore below the point where the veins meet. Sinking will be continued.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A 'DOUBLING-UP' piece is a timber used for reinforcing a set in bad ground. The term 'helper' is a synonym.

THE chief object in any plan of longwall workings is to have the permanent roadways the arteries of the system, providing the most direct route from all portions of the mine to the shaft.

THE best onyx used to come from the Pedrara quarries, near Puebla, Mexico. This source of supply is now exhausted, and small pieces of this choicestone are worth \$150 per cubic foot.

WHEN rock falls from the roof or sides of a stope, it is said to 'slough' or 'scale.' 'Slabbing' or 'scaling' of rock refers to large pieces, and 'sloughing' for the detachment of small fragments.

CALAUERITE, the telluride of gold, has been detected in some specimens from the Southern Lepanto district in the Phillipine Islands. This is the first authentic report of telluride ore in the Phillipines.

METALLIC copper, and not copper sulphate, is deposited on iron rails in the mines of Butte, by reducing action of the metallic iron on the sulphated waters of the mine draining through oxidized copper ore.

STROMAYERITE, a sulphide of copper and silver, has been found at Cobalt, Ontario. It has been found previously at Zacatecas, in Mexico, and in the Yankee Girl mine, at Red Mountain, Colorado. It is a mineral that characterizes a bonanza.

TO FIND the indicated horsepower developed by an engine, multiply together the mean effective pressure per square inch, the area of the piston, the length of the stroke, and the number of strokes per minute. This gives the work per minute in foot-pounds, and dividing the product by 33,000, we get a result which is the indicated horsepower of the engine.

THE longwall system of mining, especially as applied to coal, contemplates the extraction of the entire seam or bed, and the original significance was a continuous line of breast. After getting away from the shaft, and leaving a sufficient pillar to keep it open, no portion of the seam is allowed to remain. The method depends on producing a uniform and gradual settlement of the roof a few yards behind the working face. Pack walls are built on each side of the roadways and at regular intervals in the gob or waste area, and the roof settles firmly on these packs, pressing them into the bottom, or compressing them until the roof subsidence is complete. Longwall mining may be either advancing or retreating, with the shaft as a base.

TALC is found in nearly every State along the Atlantic slope, varying from pure foliated talc to harder steatite. Many of these deposits are favorably situated for transportation, so that it has been possible to work profitably many of the compact varieties of talc and soapstone in this portion of the country. In the Western States talc has been found in greater or less quantity at many points, but on account of their great distances from railroad transportation, only one or two of the deposits have been developed at all. In some instances nearly all of the talc

obtained from a certain State is used for one particular purpose, as that from New York, which is used almost exclusively as a filler in the manufacture of paper; and that from Virginia, which is manufactured into wash-tubs, laboratory sinks, stove-bricks, etc. The States that have produced talc or soapstone are California, Connecticut, Georgia, Maryland, Massachusetts, New Hampshire, New Jersey, New York, North Carolina, Pennsylvania, and Vermont, and most of these deposits have been described.

THE rare blue mineral identified in 1879 by Gonnard and named by him dumortierite, has been found at two localities on the Pacific Coast. One notable occurrence of dumortierite is at Clip, Yuma county, Arizona, where it so fills masses of quartz as to resemble lapis-lazuli, and at another point in Riverside county, California, it occurs in the same way, as fibres penetrating and coloring quartz. Within a few years dumortierite has been found in larger quantity and of a different tint in San Diego county, California, a few miles east of Dehesa, the place noted for its orbicular diorite. Here it appears in masses of several centimetres in either direction, with a radiating columnar structure and of a pinkish lavender color, instead of its usual indigo blue. It occurs intermingled with quartz in the lower half of a large dike, the upper half of which contains sillimanite, instead of dumortierite, similarly associated with quartz.

PORPHYRY is a general term applied to all porphyritic rocks. It is useful in describing texture or in a most general sort of classification, but is quite indefinite, and may mean any one of many widely differing rocks. The mineral constituents of porphyritic rocks are not of uniform size. There is a fine-grained or glassy portion called the groundmass, through which are sprinkled more or less perfect individual crystals of larger size, which are the phenocrysts or porphyritic crystals. Thus rhyolites, trachytes, dacites, andesites, basalts, diabases, granite-porphyrries, syenite-porphyrries, diorite-porphyrries, and gabbro-porphyrries may all be called 'porphyry,' although, strictly speaking, if the feldspar constituent is plagioclase, they should be called 'porphyrite.' The term 'porphyry' is loosely and colloquially used for almost every igneous rock in the West that occurs in sheets or dikes in connection with orebodies, and when so used, has but little significance.

THE uses of asbestos are many and constantly increasing. They depend primarily upon its fibrous character, but largely also upon its slow conduction of heat and electricity. As amphibole asbestos is less strong than chrysotile, the latter is the more valuable and useful, especially for products involving spinning. The amphibole asbestos is chiefly used in the manufacture of boiler lagging, steam-pipe covering, and insulating cements for general application. The best grade of chrysotile fiber is spun into thread, yarn, and rope, and woven into cloth. The yarn is largely used for packings and the cloth for theatre curtains, while fabrics containing asbestos woven with other fibres are made into various household articles in which heat-insulation is required rather than fire-proof qualities. It is extensively used for plastering and for making lumber that is employed throughout buildings, and especially on the roof, where insulation against fire and electricity are desired. Being a slow conductor of heat, its use contributes greatly to comfort and protection against extremes of heat and cold. Its application in fire-proof structures, and especially to envelop electrical conductors, is rapidly increasing, and the demand is said to be much greater than the supply.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Green Gold.

The Editor:

Sir—In reply to your enquiry of last week as to whether I could throw any light upon the cause contributing the green tinge or color sometimes noticeable in the appearance of gold coin and bars, I have to say that I have never attempted to investigate the cause until your letter awakened an interest in the matter, although I was aware that the presence of silver in the alloy in making gold coins influenced the shades of color in the pieces when finished. In the sulphuric acid process of refining gold it was impracticable to remove all the silver where associated with crude gold, and as the Government permitted the presence of 10 parts of silver in a thousand in fine gold, or such gold as was acceptable for coinage purposes, very much of the gold coin contained silver, varying in amount from one to eight parts in a thousand according to the conditions under which the gold was refined. Of course, it must be understood that in the coinage operations this small amount of silver figured as part of the alloy, and that much less copper was used.

While I was satisfied that the silver was at least partly responsible for the green color of gold I thought the presence of copper in some proportion was also necessary.

Upon receipt of your letter I concluded to make some experiments in alloys that would determine the question. So with the aid of Mr. Sherman and Mr. Pack of the assay department we made eight melts, with varying arrangements of silver and copper alloy, which plainly showed that it was the *silver and silver alone* which gave gold bullion and coin the green color.

The following table shows the arrangement of the metals and the resultant effects in color after melting:

1.....	(900 gold) (10 silver) (90 copper)	No green apparent.
2.....	(880 gold) (20 silver) (100 copper)	No green apparent.
3.....	(900 gold) (5 silver) (95 copper)	No green apparent.
4.....	(700 gold) (300 silver)	Decided light shade of green.
5.....	(700 gold) (300 silver) (100 copper)	Faint shade of green.
6.....	(800 gold) (100 silver) (100 copper)	No green apparent.
7.....	(900 gold) (75 silver) (25 copper)	Tinge of green.
8.....	(900 gold) (100 silver)	Decided shade of green darker than No. 4.

As No. 1 and 2 were not unlike the proportion of the alloy used in gold coinage—in fact, that of No. 2 is a condition of alloy we have frequently had—I was surprised to find no trace of the greenish shade. This, and the result with No. 6, forced me to the conclusion that copper played no part in fixing the green color. Then why should the gold coins ever show the color, is a question that naturally follows. In contemplating the query myself, the answer followed the thought. It is this: Before the coin is struck or pressed the blanks are annealed—a process which requires heating the metal to a cherry red, causing the particles of copper in the surface of the coin to form the black oxide (CuO). As the oxide is quite soluble, the subsequent dropping of the metal into a diluted solution of acid removes all the copper from the surfaces of the blanks, leaving in place a film of pure gold alloyed with what silver happens to be

in the coin. Upon reaching this conclusion I took melts No. 1, 2, and 3 and treated the samples to the annealing process with the result that each then showed the green color. This color is stable, for it can be seen at times in gold coins of issue of forty years or more past.

FRANK A. LEACH.

San Francisco, August 23.

Mining Buildings and Mining Education.

The Editor:

Sir—A few remarks will not be out of place regarding the practical and excellent speech you made at the opening of the Hearst Memorial Building, of the State University, Berkeley, on August 23; also a suggestion for its future welfare. Your comment in an editorial of the issue of August 31, concerning the patriotic speech made by W. R. Hearst is very true, but how much more true and just are your criticisms on the conduct of his daily papers. With his scope of journalism, he could wield an enormous power for good and peace in this country. Is it possible for young men to grow up good citizens, with a sense of duty, to guide their native land onward in a path of morality, not only social but intellectual, and formulate an atmosphere of peace and human kindness between men, when every morning they turn to their daily literature and read nothing but a foment of scandal and filth, capped with ideas that flaunt a red flag before their eyes, as no bomb-thrower ever did?

Your remarks concerning the public, as to its expectations and receipts, are decidedly characteristic. The average public knows absolutely nothing about mining. Mining is totally different from other business. As regards mining for gold, supply and demand, market, bulls and bears cut no figure. Mining cannot be run on 30, 60, 90 days credit system. And on this account, so many of the public who become interested in mining, imagine that it is a failure, swindle, or robbery, simply because dividends do not come pouring in within six months or a year. Many a good young fellow is ruined by such ideas. He is really far more keen and far-seeing than his company, but because his work does not show at once, they imagine him incapable of handling the proposition, never thinking nor investigating, because not knowing how, that he is laying a foundation for future and greater dividends. On the other hand, many young men, who having passed four years at a School of Mines, essay too much, and imagine they are born managers or experts. Their dreams are soon shattered and their house of cards tumbles around them, on account of a poor foundation. Again there is a third sort, I am sorry to say, that become so inflated with their self-supposed high sounding title of B. S. that nothing is beyond them. Anyone below them in position, or not so lucky, is a decided nuisance, and certainly not eligible to such exalted acquaintanceship. They are ruined because they are 'snobs,' and of course, the practical is out of the question.

The debt of gratitude due Mrs. Hearst is great indeed. She has nobly done her share, and really stands out alone in generosity. How many millionaires have the mines of California made? How much have they given in gratitude for their good fortune? Can this State point to many monuments of their generosity? What have they done with their money? Are they stingy or callous? They are both, and more, decidedly mean and contemptible. Palaces rise in the East, and extravagance, vulgar in the extreme, runs amuck, but never a thought of anything that would help their fellow man or woman to a more enlightened, refined, or successful life, nor thanks to the place that made them rich. The pro-

fessors at the University are most miserably paid. Double their salaries would not be too much, especially when we make the odious comparison of union wages today. Why not let these men that are earning \$8 and \$9 per day pay more taxes, and raise the wages at the University? Has one penny ever been donated for professorships in any way? A few chairs may have been endowed, but that did not help the ever-present needs, as it was generally for something new. The School of Mines needs more professors. The suggestion for the pursuit of practical and technical work is very commendable. It would certainly bring all the latest progress into the lecture-room. But I think I can suggest something even more advantageous to the School of Mines, the University, and the whole State.

Today California has produced \$1,450,000,000 in gold from her mines. How many millions has the University had for itself direct from Mother Earth? Not one. A few months ago, a farm was bought for the agricultural department. Has the School of Mines a mine? Why not? In years gone-by one of these properties could and should have been obtained. They went begging, and afterward under capable men, produced millions. These latter would have endowed the University, and it could have kept itself. The students could have run the mine and gained all their practical experience, and while they may have made good in the past, how much better this system would have made them. Today the University is a drag on the people of the State, and the money is flaunted in our faces by a few parvenus, who disgrace us and themselves by their ill-bred conduct elsewhere. There has been a short-sightedness somewhere, and the more regret is that it exists today.

The School of Mines should have a practical working ground, a mine—two in fact, one gold, and one copper—modern mills, and all processes pertaining to amalgamation, classification, screening, concentration, cyanidation, filter-press, etc., besides a small smelter for base ores. In this way the technical side could be brought in actual contact with the practical, and the lectures would be infinitely more effective. It would also give the students a real taste of what mining really is, and what they must expect. The course could be extended to five years with profit.

Supposing today \$1,000,000 is set aside by the State—and what better time than these prosperous days—this is a maximum figure, and it will purchase two mines and erect adequate plants for milling and smelting. The students can do the work from the start, plan, erect, etc., then develop and work the mine and mill. A small wage can be paid them, and thus have minimum expenses, and enable many to get through college. With good judgment in the beginning, and capable management afterward, handsome interest can be realized from the investment. This would yield a monthly income, permit of raising the salaries of the professors, and more besides. The State in general would be relieved, and I think in time, the University might become self-sustaining. It is perfectly certain that a farm will never sustain the State, nor even the Agricultural Department.

The average student today considers mining much as a pastime, because he is not initiated into its true life generally, until he has graduated or gone too far in his studies to throw up his chosen profession, should he not like it. True, they go to a mine during vacation for a few weeks, but there the foreman always gives them a snap job, and in the evenings the girls in town go crazy over their bell-topped pants. Mining is really a hard life, but it is most fascinating, and when a man has attained an honest eminence in mining, he has attained something that all the other professions cannot equal. And although he can

attach a yard of letters donated by societies to his name, the proudest of them all is the M.E.

C. O'BRIEN.

Oakland, September 10.

MEXICAN MINING CONCESSION.—A concession for the development of the Guanajuato mining field has been granted to a company of Guanajuato. The intention of the company is to sink a 1,000-metre shaft for the purpose of investigating the ores which are supposed to lie deep underground in the State of Guanajuato. As the enterprise is one of great public importance, and as the Mexican Government has for some time contemplated a geological exploration of this nature, the company has been granted a direct subsidy and certain rights with relation to the other mining companies operating in the same district. The contract is to run for 10 years from February 4, 1907, and during its lifetime the company shall be exempted from the payment of all Federal taxes, with the exception of the stamp and mine taxes and assessments on capital, bonds, shares, buildings, roads, and works of the company. The import duties on the machinery for this enterprise and for the plants where the ores are to be treated shall be returned to the company. This exemption shall only apply to the machinery imported before June 30, 1908. Students of the National School of Engineers will be permitted to practise in the mines being worked and also in the reduction plants which the company may construct. The company and those who may succeed it in its rights, as well as the employees and other persons interested in the company, shall be considered as Mexicans in all matters having relation to this contract, and shall be subjected exclusively to the jurisdiction of the courts of the Republic.

USES OF COBALT.—The characteristics of the metal cobalt and its compounds are much like those of nickel and its compounds. The methods used for extracting one metal from its ores are similar to those used in the case of the other. Since these methods are complicated, an attempt will not be made to describe them. The reader, desirous of a knowledge of the methods, is referred to some standard work on metallurgy, such as that of Schnabel. In former times cobalt glass, 'blue color,' was made directly from some of the purer ores carrying cobalt, nickel, silver, and arsenic. Most of the arsenic was first roasted off, and to the residue were added the constituents of potash glass—powdered quartz and carbonate or other compound of potash. The roasted ore, with these constituents added, was then melted down, the cobalt uniting with the glass to form smalt and the nickel and silver settling to the bottom of the furnace. If a little arsenic was not left in the ore some of the nickel would also combine with the glass, thus injuring its color. The blue glass, or 'smalt,' was powdered and sieved, and was then ready for the market. Cobalt now comes on the market in the oxide form, the latest quotation being \$1.60 per pound for the pure oxide, CoO. There are seven or eight manufacturers of this oxide in Europe—three in England and two or three each in France and Germany. Little cobalt is used in the metallic form, owing to the fact that nickel serves practically the same purposes as metallic cobalt and is much lower in price. It is said that a little cobalt added to nickel in plating tends to produce a more silvery and less steel-like lustre. By far the largest consumers of cobalt are the potteries.

A NUMBER of mills on the Rand show a duty of over 7 tons per stamp; in July the mill of the Luipaard's Vlei Estate crushed 8.5 tons per stamp per day. This increase is due to the use of tube-mills.

Square-Set Mining and a Modification of it.

Written for the MINING AND SCIENTIFIC PRESS
By CLAUDE T. RICE.

In a former article I tried to bring to the attention of mining men the importance of systematic study of the shape that caved workings assume in different rocks. This shape, which the roof assumes when equilibrium is established between the force of gravity and the strength of the rock, was termed the 'dome of equilibrium.' I believe that the variable factor, namely, the strength of the rock, is fairly constant; consequently the shape of this dome is fairly fixed in each kind of rock. The subject is one well worthy of study by mining men, and if such a systematic study becomes general, a decided advance will result in practical mining.

In this article I wish to call attention to some of the anomalies of the ordinary mining by square sets, preparatory to describing a proposed modification, which I hope mining men will deem worthy of discussion.

In the early days of square-set mining the attempt was

wheel-barrow has assumed a regrettable prominence. Here again experience is coming to the rescue. Frequently one hears the present-day foreman, when re-opening some old stope, curse the departed foreman, who only placed chutes every 75 or 100 ft. along the vein. The shoveler realized this mistake quite a while ago, the foreman realizes it now, and the superintendent is beginning to appreciate the absurdity. Indeed, it seems probable that in the future the chutes will be carried up at least within speaking distance of one another and that in time wheelbarrows will become obsolete in square-set mining. I believe that a distance of 25 ft. is none too close for chutes in square-set stopes.

Generally in the waste-filled stopes only the two top floors, the drilling floor and the shoveling floor, are kept open. This fact has caused the roof to degenerate from a dome to a flat. As in the case of the slide, although one might infer to the contrary from the descriptions given in mining papers, the practice in unfilled square-set stopes has blindly followed the practice of the filled ones, and the roof in the former is at present almost as flat as in the

Stope represented above shows the way of extending stope to boundary of pillar in heavy ground by means of temporary chutes and slides, contemporaneous waste-filling being necessary to hold open the stope. Generally the stope could be extended to the pillar, without filling, until that is reached.

Stope represented above is in normal condition. The slides send the ore to permanent chutes situated at the pillar-boundary, which later serve as chutes to the pillar-stope. The central raise, down which the waste-filling is dumped, is closed at the bottom by a trap-door; consequently the air is forced past the working faces, where it is needed. Moreover, the shape of the stope promotes ventilation.

made to extract the ore without giving any support to the walls of the stopes other than the timbers. Many disastrous caves resulted, until it became evident that, in general, as the ore is extracted, the sets must be filled with waste rock. As a result there have been developed two quite different systems of square-set mining, namely, without filling and with filling. The first characterizes the camps of Leadville, Bingham, and the Ceur d'Alene. The second obtains at Butte, Montana, and at Bisbee, Arizona, where the country rock is not as strong as in the districts just mentioned.

In the early days when using square sets the roofs of the unfilled stopes were domed and liberal use was made of the slide for getting the ore into the chutes. But when experience dictated the filling of stopes with waste so as to prevent caving, the slide disappeared and now even in the open stopes of Bingham, and I understand of Leadville, slides are conspicuous by their absence. It seems that, having been tabooed owing to necessity in the filled stopes, slides also fell into unwarranted disrepute in the unfilled ones.

Formerly, owing to the use of slides, chutes did not have to be placed close together. When filling began to be used, the long chute-interval was retained, but owing to the impossibility of using the slide to advantage, the

stopes where filling is absolutely necessary. Often these flat-roofed square-set stopes are 70 ft. wide and 100 to 150 ft. long. The weight in them is very great; often even 12 by 12 in. Oregon pine timbers are unable to resist the pressure. Doubling-up timbers have to be inserted to hold up the back and, in the large stopes, frequent bulkheads become necessary to keep the sets from swinging until the floor can be mined and waste can be brought to fill them.

In unfilled stopes, such as those at Leadville and Bingham, I believe the greatest weight is a side weight. But in such districts as Butte and Bisbee, where the waste-filling is kept within two sets of the back and only such space as is absolutely necessary for convenient mining is unfilled, I believe the greatest weight is downward. I do not see how the side weight on the timbers can be very great as the back of ore and the waste-filling, only two sets below, must resist most of it. Besides, in these flat waste-filled stopes I have never noticed much sign of side pressure. The crushing of the timbers is mostly at the horns of the caps and girts where they rest upon the shoulders of the posts. Here all the top weight on the caps and girts is concentrated; unfortunately this is across instead of along the fibre of the wood. Doubling-up pieces are required to support these timbers; then, as the

top-weight increases, bulkheads become necessary in order partly to hold up the back, but mainly to keep the sets from 'jack-knifing' or 'riding' under the top weight.

By contemporaneous filling of the stope we cheaply and efficiently resist the side weight in them, but at present we take care of the top weight in a far cruder manner. The solution of the problem of the side weight has forced the adoption of flat-roofed stopes in which the top weight becomes a maximum. Is there not a way to bring this top weight to a minimum while we resist the side weight by means of filling? Must a waste-filled square-set stope have a flat roof? I think not.

The miner, running even so small a working as a drift, arches the roof because he knows that it saves many a bump on the head and much cleaning of track, which would result from the falling of small slabs of ground in case the roof were flat. The experienced miner barring or picking down a back (unconsciously perhaps, for this knowledge of the arching of roofs has become almost instinctive in him) forms his judgments as to where to test the back from the nearness of its shape to that of the arch that he would expect in such a rock. He uses blocking over each post of the square-set partly to keep the caps and girts from being blasted out but also to sustain the back. He knows that the ore is usually strong enough to arch itself over a space of five or six feet and that thus he can concentrate the weight of the roof over the posts and to a great extent save the caps and girts; and this feature of top blocking is especially impressed upon miners that have worked in the soft oxidized ores of Bisbee and of Leadville. When the top blocking is left out in such ground the roof settles down bodily upon the timbers and in time the lagging is broken by the weight. Besides, when mining progresses to the floor above, these timbers are apt to be broken in case blasting is necessary. But when blocking is used, the roof, after a little sloughing, arches itself. Owing to this deadening of the floor and to the fact that the ground has not settled down either on the timbers or the lagging, there is no anxiety at blasting time.

Everywhere in mining we see use made of the dome of equilibrium, but at present in square-set mining little advantage is taken of it. I believe that in taking full advantage of the self-supporting property of the arch lies the correct method of withstanding the top weight. It is not by using large timbers, doubling-up pieces, and bulkheads. Instead of making the roof flat, the roof ought to approach (as nearly as other conditions will permit) the shape of the dome of equilibrium for that kind of ore. Then the rock supports itself. In this proposed modification of square-set mining, the first step would be to run a two-compartment raise to the level above, the raise being in the centre of the block to be mined, with its long axis across the strike of the deposit. This raise gives good ventilation to the future stope and is necessary for filling it with waste. After the raise has been holed, square-set stoping would begin at the bottom. The stope would be carried from the foot to hanging wall and, as it enlarged in width along the vein, it would also be increased in height so that the roof would approach the shape of an arch previously determined.

The shape of this arch would be determined by three considerations: In order to mine cheaply it is necessary to keep down the cost of timbering, of mucking, and of filling the stope. In order to make the cost of timbering as small as possible, full advantage must be taken of the self-supporting power of the ore itself. To do this the roof must approach the shape of the dome of equilibrium. To bring mucking to a minimum, the rock must be

handled by gravity as much as possible; wheel-barrows must be eliminated. The cheapest way to solve the mucking problem in square-set stopes is to blast the ore onto slides that carry it to the chutes. Therefore, the shape of the roof must be such that the slides can be given sufficient pitch to carry the ore easily. In order to make the filling cost a minimum, full advantage must be taken of gravity in filling the stope with waste. As the angle of repose of broken rock is about 50° , in most cases cars and slides must be used to aid in filling the stope.

As, in this proposed method, we are going to use slides for transporting the ore to the chutes, we can by slight changes use these also for sliding the waste into those sets that otherwise would be hard to fill. Consequently, in this method the angle best adapted for getting the ore out is also suitable for getting the waste in. The roof of the stope ought to approximate as nearly the dome of equilibrium as the angle necessary to allow sliding of the ore will permit. The only data known to me, in regard to the shape of the dome of equilibrium, is the following taken from *Mines and Minerals*.^{*} In shales, slates, and rocks breaking into a foliated condition the angle from spring of arch to crown is 30° , consequently the height of the arch is one-fourth the span. In sandstones, limestone, conglomerates, and rocks breaking into large irregular pieces the angle from spring of arch to crown is 60° , consequently the height is seven-eighths the space. Rock will slide on a board chute at an angle of 30° . In many ores sliding occurs at a somewhat lower angle. Therefore the above data would indicate that in most rocks the shape of the roof can approach quite nearly the dome of equilibrium, and still the ore-slides can be given sufficient grade for their proper working, consequently the roof of the stopes under the proposed method would be made to assume the shape of the dome of equilibrium. Two sets below the back a series of slides made, say of 5 by 10-in. timbers, and resting upon the caps, would be inserted. The ore would be blasted down on this main slide, which would carry it to the chutes placed at intervals in the line of sets marking the boundaries of the block to be mined. To prevent boulders getting into the chutes, grizzlies would be placed on the top sets under the spots where blasting was to be done. As these grizzlies would be composed of 5 by 10-in. or 8 by 8-in. timbers, with blocks of wood for spacers, all merely resting on the caps and held in position only by wedges, they could easily be moved to another set as mining progressed.

The space between the slides—for the stope would be symmetrical with respect to the central raise—would be filled with waste sent down through the raise. In many stopes, owing to their shape, complete filling by gravity would be possible, but in most stopes portions would have to be filled by means of a car and slides. As indicated above, by slightly changing the ore-slides, they could be used to slide the filling wherever desired. As the stope progressed, the slides and grizzlies would be raised a set at a time and the new open space between the slides would be filled. Thus the stope would be kept completely filled except for the two sets next the roof of the stope. The foregoing description presupposes that the vein material and the country-rock are strong enough to stand until the stope can be enlarged to reach the boundaries of the block. In case that is impossible, temporary or 'joker' chutes would have to be carried up through the filling and used for getting out the ore until

^{*}Vol. XXII, p. 36. In this article entitled 'Principles Relating to Post Timbering,' the arching is attributed to the fact that the roof slabs off into irregular boulders which interlock and key one another, forming the arch. I think, on the other hand, that the arch is due more to the inherent strength of the rock than to the binding of the slabs that scale off from the roof.

the boundaries were reached; then the permanent chutes would be used and the 'joker' chutes abandoned.

In the method thus described the top weight, owing to the shape of the roof, would be supported mainly by itself. The side weight in the upper portion of the stope would be carried by the timbers, in the lower portion the waste-filling would support the walls. In the top portion of the stope the timbers would be greatly strengthened by the pyramid of waste, which would completely fill all the sets except the two adjacent to the roof. This filling would steady these sets and all danger of their swinging would be avoided. This would permit the mining of much larger blocks of ore than would be possible in the same ground in case that a flat-roofed stope were used. Owing to the fact that the timbers in the two sets below the roof would be subjected to considerable wear and tear from the rocks passing down the slides, round timbers would be better than square ones in the square sets. These round timbers are best framed similar to the Brunton system, in vogue in many of the Butte mines of the Amalgamated Copper Co. As the timbers are only subject to wear for a comparatively short time, this wear and tear ought not to damage them seriously. The bottom of the central raise would be closed with a trap-door. This would prevent the short-circuiting of any air and consequently all the air would have to pass up through the stope past the working faces and up through the upper portion of the central raise to the level above. The shape of the stope ought to aid greatly in producing good ventilation.

In the method as outlined the arch has been made to run across the vein, and it has its foundations on the ore. This gives a stronger foundation than if the axis of the arch ran with the vein, for the cohesion of the ore within itself is greater generally than the adhesion of the ore to the walls of the vein. The above would be the method used in mining the first blocks or 'rooms,' but in mining the pillars the axis of the arch would run along the vein, for, as the ore to each side has been previously mined, we would have to depend upon the adhesion of the ore to the walls as the main support of the arch in the pillar. In the pillar the greatest pressure would probably be from the waste-filling to either side, and not from the wall-rock, for the walls are held apart by the back of ore above and the waste-filling below. Owing to the fact that the ore would be slid into the chutes, a stope could be mined much more rapidly than in an ordinary flat-roofed square-set stope. Moreover, owing to the shape of the stope it can be filled with waste quickly, and so what might in the case of a flat-roofed stope be a bad cave, could in this arch-roofed stope be prevented. Both of these possibilities, that of quick mining and of quick filling, are advantages not to be despised. By this method full advantage is taken of the self-supporting power of the ore, thus decreasing the cost of timber; full advantage can be taken of gravity in extracting the ore and introducing the waste-filling, thus bringing the cost of mucking and filling to a minimum; owing to the shape of the roof, ventilation ought to be much better than in a flat-roofed square-set stope. In exceptionally heavy ground, it would be possible to dome the roof of the stope instead of arching it only one way. Possibly experience may prove that it is better to have the axis of arch across the vein instead of along it in the pillar stope and the axis along the vein in the rooms. While the slide is given much prominence in this method, its wholesale use is not essential, for, by advancing chutes through the filling and using short auxiliary slides, the arched shape of the roof can be retained and the wholesale use of slides abandoned.

I close this article with the request that mining men

will criticize the proposed method. As it is only a paper method of mining, it doubtless has many flaws in it at present, but I hope there is sufficient merit in it to point toward the right direction in regard to bettering square-set practice. Possibly it errs in too liberal use of the slide, but I hope not. At present, about the only advantage taken of gravity in waste-filled square-set stopes is that the ore falls upon a good floor. Ought not better advantage be taken of gravity?

VANADIUM AND URANIUM are nearly always named together, as almost all ores containing one metal also contain the other. Uranium, however, is used but little for steel-hardening purposes outside of the well known German steel foundry and gun factory of Krupp at Essen, where the use of uranium has apparently passed out of the experimental stage, but where the knowledge of its application is guarded most jealously. Vanadium, on the other hand, has been used in France and Sweden for many years for increasing the tensile strength and toughness of steel, but its high price has prohibited its application on a large scale. The French and German armor-plate works use an alloy of vanadium and nickel and obtain excellent results and the superiority of French automobiles is said to be due to the liberal application of vanadium steel in their construction. Uranium has been detected in more than a dozen different minerals, which are found in nearly all mountainous countries of the globe, but the percentage of the uranium is generally too small to warrant extraction, and workable deposits of uranium minerals are limited. Since the discovery of radium these uranium minerals have become of special interest, as the percentage of uranium is in direct proportion to the radio-activity of the mineral, and all other applications of uranium metal and uranium salts, which latter are used to some extent as color on porcelain and glass, are overshadowed by the importance of uranium as the chief source of radium.

FRENCH RESPIRATORY APPARATUS.—The minister of public works has recently issued a decree ordering the employment of respiratory apparatus in the mines of France. Every mine employing 100 men underground at the same time must be provided with portable respiratory apparatus, ready for immediate use and allowing a miner to remain at least one hour in an irrespirable atmosphere. The number of these apparatus must be not less than two for each pit, placed in charge of an engineer or inspector familiar with their working, and provided with 10 picked men, who will be trained in the use of these apparatus and sent to the seat of danger immediately whenever the necessity arises. A year is allowed each mining company to comply with the stipulations of this decree. These precautions have been suggested by the great disaster of Courriers last year.

IN MEXICO, near Pachuca, in the State of Hidalgo, are great prehistoric obsidian mines. At this point, though the material exists in such quantity, yet the outcrops are all buried under the heaps of debris and fragments left by the ancient workers. Near Tequisquiapan, in the State of Queretaro, there is another locality some 60 or 70 miles west of the former, where a similar obsidian occurs abundantly, but does not appear to have ever been mined or developed, and where the outcrops are entirely accessible. The place is near the border of the States of Queretaro and Hidalgo, on a range of low hills east of the San Juan river, between the crossing of that stream by the Mexican Central railroad, at San Juan del Rio, and by the National Railroad of Mexico a few miles below.

Dumping Residue at Kalgoorlie.

Written for the MINING AND SCIENTIFIC PRESS
By M. W. VON BERNEWITZ.

It is doubtful whether any mining centre in the world has been so troubled with the disposal of its mill residue as Kalgoorlie. The area of 12 of the producing mines, on what is known as the Golden Mile, is about 430 acres.

old, as well as the present residue, contains gold enough for profitable re-treatment, so it is best to have it near the treatment plants. On a windy day—and we get plenty of it here—the dust (ranging from 20 to 200 mesh) flying about the mines is terrible, and a great deal of damage is done to machinery through it. There are several methods for disposing of the residue, namely, trucks drawn by horses, Robins belt-conveyors, a combination

Fig. 1. General View of the Kalgoorlie Mines.

There are many single mines in the world that cover this area alone; here it is divided among a dozen, and it is covered with the head-gear and hoists of a score of large shafts, together with the machinery necessary for the reduction of about 4,300 tons per diem. In the earlier days of the field, little attention was given to the disposal of residue, and it was dumped all over the

of these two systems, the Bleichert system, and trucks drawn by electric locomotives.

At the Associated mine about 320 tons are discharged daily from seven presses onto a horizontal Balata belt, which discharges into trucks at the dump, and these are taken out by horses. An inclined belt is to be erected shortly. Having practically covered the best part of its

Fig. 2. Associated Northern and Oroya-Brownhill Dumps.

leases, but when the big mills commenced working at their maximum capacity, this matter became a difficulty, which, on several of the mines at the present time, is causing great expense. Compared with the ore that is extracted from underground, very little residue is sent below for filling depleted stopes. Certainly it could be railed right away from the mines, but in most cases the

property, the Associated Northern Blocks recently erected a conveyor to elevate its slime, discharged from three presses at the rate of 120 tons per diem. There is a horizontal Balata belt feeding an inclined belt, at an angle of 27°. The photograph (Fig. 2) shows how the latter belt is erected on top of the old dump, and a scraper fixed across enables the slime to be thrown off at any desired point, so as to fill around the structure. All the belt-conveyors are of the Robins type.

*The photographs illustrating this article were taken for the author by Mr. F. Goyder, on the staff of the Associated Northern Blocks.

The largest system of rubber belt-conveyors is at the Golden Horseshoe, which puts through its 18 presses about 600 tons of slime daily. There are about 80 tons of sand discharged daily from the leaching vats, which is sent below. The Horseshoe presses are in three rows, under which are a like number of belts, that discharge onto a very long belt running up to the dump. This belt in turn feeds another at right angles to it, running the length of the dump, this one finally discharging onto

haulage, as shown in Fig 3. Now and again a large heap of slime will slide from the top of this dump to the bottom, making a channel on its way. The elevator is motor-driven. Since writing the above, the Ridgeway slime-plant has been working, and the residue from the 10 machines is mixed with water and pumped about one mile distant, where it settles.

The Ivanhoe crushes about 620 tons of ore daily with its 100 stamp-mill. (See Fig. 4.) There is the treatment

Fig. 3. Great Boulder Proprietary Dump. Lidgerwood System on Left; Bleichert on Right.

a horizontal stacking-belt. All belts are motor-driven.

The Great Boulder Perseverance takes about 500 tons daily right off its lease to an area one mile distant. The system is as follows: Under each of the 11 presses is a belt, which feeds a main collecting-belt, in turn feeding another at right angles that discharges the slime into side-tipping trucks, holding two to three tons each.

of sand, slime, and concentrate. About 50% of the sand, say 150 tons, is sent below into the mine, the balance being trucked to the circular dump, along with the treated slime and concentrate from eight presses, by an electric locomotive.

Three hundred and thirty tons daily is trucked from the six presses at the Kalgurli. This company has very

Fig. 4. The Ivanhoe Dump.

These are taken away by an electric locomotive. The belts are made of rubber and are motor-driven.

Some elaborate systems have been, and are being, worked by the Great Boulder Proprietary company. For some years a Lidgerwood hoist with flying fox was used, making a heap some 60 ft. high. All the spare room being filled up, an elevator on the Bleichert system was erected near the cyanide-plant. Some 140 tons of fairly wet slime is dumped per diem from the 13 presses into trucks, and then elevated by the endless wire-rope

little dumping room left, but adjacent vacant property will probably be used. About the worst sufferer for lack of space is the South Kalgurli, which has only 11 acres. Discharged daily from the seven presses, 280 tons of slime are elevated by an inclined belt at 24°; this feeds a swinging-boom belt inclined at 27°. All the belts are motor-driven. The Lake View Consols trucks about 350 tons per diem from its nine presses to a large circular dump. This company will soon have to elevate.

Probably the finest example of belt conveyors and a

swinging-boom stacker used in piling residue is working at the Oroyo-Brownhill. About 350 tons daily are discharged from the six presses onto two belts, which feed a cross-conveyor, this in turn delivering to an inclined belt. The latter finally feeds the boom-belt, which can be moved around 180°. All belts are of rubber and motor-driven.

The following are some published costs of dumping:

The accompanying photograph of Kalgoorlie illustrates the peculiar flatness of the country, rendering necessary devices for conveying.

The National Forests.

A point in the industrial progress of the United States has now been reached where development of the country is made, not in the face of the forest, but with its essential aid. The old process of exhausting the supply of timber in a region and then seeking new fields is practically over. Already the lumber industry is turning back on its tracks. A quality of timber is eagerly sought in the Lake States which a few years ago was ignored as utterly worthless, and in the South the whole pine region is being gone over in a close search for the old field pine, a tree once despised but now bought up at prices much higher than those formerly paid for the magnificent timber of the virgin forests.

Abuses have grown up under the laws that provide for the disposition of public land, notably the segregation of large holdings of timberland for speculative purposes. Timber from the National Forests is now purchased by the thousand board feet and payment is made upon the actual scale of the logs when cut. Two dollars and a half per thousand feet is comparatively low as present charges go, but since the cut ranges from 5,000 to 20,000 ft. per acre, the Government receives from five to twenty times as much for the timber as it did under the Timber and Stone Act. Public opinion now demands, not that the Government should dispose of its remaining timberlands as rapidly as possible and leave it to private enterprise to exploit the forest hastily, but that what remains of the National Forests should be more conservatively used. The Government has been forced into the lumber business solely in order that a supply of forest products may be guaranteed to future generations.

Probably 65% of the total stand of merchantable timber within the Forests is on the Pacific Coast, where for a long time the enormous supply of privately owned timber will satisfy most of the demand. This more accessible private timber surrounded the Forests as the meat of an apple surrounds the core. It has been entirely eaten away in many places, while in others it is locked up by speculators. The thing to remember, then, is that this immense body of public timber is there as a great reserve against the time when private timberlands will be depleted, and for use as a weapon against monopoly.

The first effect of National Forests upon prices, particularly where there is still a great deal of available timber, is to raise the price of outside stumpage toward its actual value by withdrawing the excess supply of low-

priced timber from the market. But later, as the supply of timber dwindles and values are forced upward by speculative holdings, the effect of the Forests will be to check the advance of prices. In the virgin forest, growth is just about balanced by decay. In the Western forests, however, natural deterioration is greatly augmented by forest fires. The fires usually do most harm by damaging merchantable timber, but, great as this injury is, vastly more actual loss in forest wealth results from the yearly burning over of the grass and undergrowth of the forest. Ground fires do not consume the large trees, but they destroy seedlings outright and injure growing trees so that they quickly decay. Finally, the forest floor, composed of a mold of needles, twigs, and mosses, is burned away.

Far beyond the influence of the National Forests upon the lumber supply will be their importance in the future. The United States is now facing a shortage in the stock of available timber. The yield from the National Forests will aid greatly to bridge over the period in which mature timber will be lacking, a period which will last from the time the old trees are gone until the young trees are large enough to take their places. The definite result, therefore, of the sale of timber from the Forests will be to sustain the lumber business, to maintain a steady range of timber values and so discourage speculation, and, far more important still, steadily to further the uninterrupted development of the great industries dependent upon wood.

CONCRETE has solved many a vexing problem when it has been necessary to find substitutes for costly structural materials subject to rust or decay, and lately there has been added to the list the concrete mine support as the successor of timber. Now that the 'trick is done,' the only matter of surprise is that concrete was not utilized for this purpose long ago. The successful application of concrete in the Philadelphia & Reading collieries, near Shamokin, is a striking example. Apparently it was not a difficult engineering feat to accomplish. The concrete arches were not introduced to a minimum weight, but tried at a point which formerly needed heavy timbers that were frequently broken. Concrete arches not only answered the purpose, but were constructed at a cost ranging from \$22 to \$27 per arch. So successful has been the outcome that concrete is gradually supplanting timbers in the collieries referred to, and ultimately wood will be dispensed with entirely. The success of the experiment is highly important to the mining industry, as the timber bill has been an item of no small moment. But aside from the economic considerations, there is another point of interest. It is the fact that in this case, as in nearly every other instance where skilled engineers supervise the work, concrete has proved worthy of the confidence reposed in it. —*Cement Age*.

THE Mexican Central railway is taking 4,000 bbl. of fuel oil daily from the Mexican Petroleum Co. The cost is \$1.10 per barrel, or a total of \$4,400 daily. The Mexican Central is steadily increasing the number of oil-burning engines in service, and within the next few months the road will be taking much more fuel oil than at present. All new engines purchased by the Mexican Central are equipped for burning oil, and engines are being constantly remodeled in the general shops at Aguascalientes. Oil-burning engines will be soon placed in service on the Chihuahua and Guadalajara divisions of the Central. Storage tanks are being prepared at Guadalajara, Yurecuaro, Zapotlan, and La Vega, and metal delivery tanks are now being erected. Some oil has been unloaded at Guadalajara and Zacatecas.

The Institute and Advertising.

The correspondence published in the next column is self-explanatory. It relates to a matter that has provoked a good deal of discussion among members of the Institute and yet it is a subject difficult for a technical journal to discuss because it deals with a field of activity in which there might be supposed to be some competition. However, this feature is negligible, especially if the reader will give credit for motives other than those arising from self-interest. The exchange of letters between a group of representative Western mining engineers and the Secretary of the Institute puts the question of advertising squarely before the members. Mr. Courtenay De Kalb and his friends recorded their objection in a practical way, by offering to subscribe toward the funds evidently needed, and Dr. R. W. Raymond replied in his usual effective manner. Obviously the Institute has incurred financial obligations that it is impossible to meet out of the annual dues from members and, in order to overcome this difficulty, it was decided to sell advertising space in the Bulletin. Advertising pages certainly do record "the state of the art" and they have a historical value, but we doubt whether many keep them for such a purpose; on the contrary, to most people the advertising page has a distinctly ephemeral value, for it indicates the best machinery available at the moment. When such pages are old, they become out-of-date. Not many members of the Institute are engaged in writing the history of the art; most of them are doing the work of the day with the latest appliances. Moreover, the Bulletin of the Institute is so bound as to enable the members readily to detach the advertising pages and to separate any article of particular value. The advertising is less an integral part of the Bulletin than of an ordinary technical journal. However, here we tread on dangerous ground.

The real problem is how to obtain the money needed for the Institute. If advertising is objectionable, how else can it be done? To increase the dues would work a hardship on many members, particularly the younger men, to whom the Transactions are of especial value. The initiation fee might be raised, but this would be ineffective, as it would apply only to new members. It has been suggested to form an inner circle of 'Fellows' or some other sub-division of select men, that is, those specially qualified by training and experience, after the model of the full members of the American Society of Civil Engineers. But we do not advocate this. Quite the contrary. The Institute has a character—or lack of character—that is not likely to be altered at this date; it is frankly democratic, and has long since failed to give any diploma of engineering ability or professional reputation. Not to be a member argues a mining engineer to be a crank, to be a member indicates nothing in particular, save the desire to obtain regularly a large body of technical information excellently printed and edited with a rare skill. What is to be done? The problem has manifestly not been solved by the little advertising obtained for the Bulletin. The difficulty facing the management of the Institute still exists. We shall be glad to offer our pages to members desirous of discussing the matter.

On January 1, 1907, the Institute had 4,018 members and associates. Many of these live in foreign countries, so that the cost of sending circulars, bulletins, and volumes is increased by the higher rates of postage. About 400 members live in New York and the adjacent portions of New Jersey and Connecticut; it is to them that the new building of the engineering societies is of particular interest and use. The letters follow:

DR. ROSSITER W. RAYMOND,

Sec'y American Institute of Mining Engineers, New York.

DEAR SIR: We, the undersigned members of the American Institute of Mining Engineers, being apprised of the inadequacy of the funds derived from membership fees for the support of the activities of the Institute, and regretting a resort to the use of the Bulletin as an advertising medium, respectfully offer ten dollars (\$10) each, in addition to their regular dues, toward a fund to be applied in such manner as the Council may approve.

We hope that this contribution on our part may constitute the beginning of a general voluntary offering by the members, being convinced that practically all would be willing to respond in such an effort to relieve the Institute from financial stress.

(Signed)

SEELEY W. MUDD,	COURTENAY DE KALB,
JOS. P. GAZZAM,	MARTIN J. HELLER,
WM. S. NOYES,	H. W. TURNER.

August 20, 1907.

PROF. COURTENAY DE KALB,

121 E. Ave. 49, Los Angeles, California.

MY DEAR SIR:—

Your favor of August 20, with enclosed letter from yourself and Messrs. Seeley W. Mudd, Joseph P. Gazzam, H. W. Turner, William S. Noyes, and Martin J. Heller, and checks from the signers to the aggregate amount of \$60 (namely, checks for \$10 each signed by Messrs. Turner, Noyes, and Heller, and your check for \$30) is at hand.

The present financial situation of the Institute involves two separate burdens, namely, (1) the extra current expense of our housekeeping in the new building; and (2) the annual installment of principal and interest on the ground occupied by the building. (Mr. Carnegie gave the building, but not the ground.) The second we must pay by subscriptions; our one-third amounted to about \$180,000. We have paid off about \$60,000, I believe. The first item—that of increased annual expense—represents, of course, increased space and facilities, and especially a practically new department—that of a library well fitted up and administered. We are very anxious to meet the extra annual expense without increasing the annual dues; and I hope this will be done by means of the advertisements in the Bulletin.

You will see that this part of the case is not to be met by subscriptions. I do not think it could be met even by doubling the membership at the present rate of dues, if that were possible. The fact is, that we are giving for \$10 a year a little more than we can afford; and we are determined neither to lower the amount and value of our publications nor to increase the annual dues. At all events, we shall try the experiment.

I do not understand the objections which a few members have expressed to the addition of an advertising supplement to the Bulletin. My own experience of 50 years leads me to value advertisements *for preservation*, often more highly than the text. After a couple of years, I look through old advertisements in periodicals for evidence as to "the state of the art," the names of manufacturers, etc. Whoever has not learned their importance has something yet to learn.

We will turn over these checks to the Land fund, unless you object. I have directed the bookkeeper to hold them in the safe for a few days, to give opportunity for a reply from you.

Yours truly,

R. W. RAYMOND,
Secretary.

Old Methods in Mexico.

From a report made by E. Tilmann, Royal Prussian Commissioner of Mines, in 1865, we get an interesting glimpse of conditions at Guanajuato as they appeared to an experienced mining engineer forty years ago. Herr Tilmann was on furlough from the Royal Mine office of Dortmund and made an elaborate report on the mining properties owned by the Sra. Doña Francisca de P. Pérez Galvez, the lone survivor of a family famous in the historic development of Guanajuato. This report was published at Münster in 1866. It is a long document and contains many valuable notes. In regard to the methods of mining, Herr Tilmann says:

"Each mine has its *bocamina* (or *boca de mina*), that is, an opening or inclined shaft for exit, which is furnished with steps; at a depth of 30 or 40 m. is a large room converted into a chapel. From here on the stairs follow the dip of the vein (45°), but sometimes they have a slope of 50 to 70%. It is a very uncomfortable ascent to climb on these stairs from a depth of 500 metres.

"The ore extraction is done by men, the *tenateros*, mostly Indians, who carry the ores in sacks (woven from aloes) upon their backs; from the two upper ends of the sack hangs a wide band which the man, who carries the ore, puts around his forehead and so prevents the sack from slipping, thus leaving his hands free. The ore-carriers bow under the weight and in steep places only do they support the load with their hands. One cannot help admiring the strength of these men, usually loaded with 225 to 350 lb. I have often seen a man carrying 18 to 22 *arrobas*, that is, 450 to 580 lb. through very uncomfortable, scarcely passable drifts in a mine temperature of 12 to 25° . Main working passages to any degree regular and comfortable are not in existence. The ore-carrier picks his way through one of the passages which he considers the best. These men work entirely upon contract and obtain 22 centavos per *carga* (3.5 cwt.) for a 100 m. distance, earning 75 cv. in 12 hours. The ore is thus brought to the *despacho* (ore-bins) and is then hoisted to the surface in untanned cow-hides (*mantas*) by *malacates* turned by four horses. Such a load weighs 10 to 12 cwt. Hoisting from the shaft costs 5 cv. per *carga* per 100 metres."

The temperature underground is stated in degrees Réaumur; 12 to 25° R. would correspond to 60 to 88° F. The Indians are the *peones* or Mexicans of unmixed native blood. By 'aloes' he means the *maquey*, the fibre of which is used for many purposes. Next he describes the system of wages and marketing of ores. Similar methods persist to this date in some of the mining districts not invaded by foreign ways. The *buscon* or tributer is still an important man in Mexican mining. Appraisal of ore by eye, without weighing or assay, survives at Pachuca to this day, the appraiser being known as the *rescatadero*. The method of testing ore by washing in the *jiacara* resembles the vanning shovel of the Cornishman, the *bateu* of Brazil, the pan of the Californian, and the horn spoon of the prospectors in Arizona. The horn spoon is the direct descendant of the *jiacara*.

Herr Tilmann says:

"Mine administration entirely corresponded with the business. The common 'wage system' was as follows: Permission to individual laborers was given to work in the mines; the same could employ on their own account other laborers, drive drifts, and open stopes, in fact carry on all the prospecting they pleased, so that they might find ore. (Hence the name of *buscones*, or searchers.) They were usually given powder and tools free, but had to pay for lights and for hoisting ore to the surface. A *buscon*, finding ore, had the right (not by mining law, but by custom,) to mine the same for his own account.

The ore produced, if rich or poor, was always divided into two parts; the *buscon* received one-half as wages for his work, and he had the choice to sell the ore himself or through the mine agency. The other half was amalgamated by the mine-operator in an *hacienda* under a tax determined by the law, known as the *maquila*. The *hacenderos* (proprietors of the amalgamation works) deducted the amount of the treatment charge for amalgamation out of the silver yielded and gave the remainder to the mine-operator. Only this latter amount of silver was registered in the books as the production of the mine. Besides the work of the *buscones*, some mining was done on contract and wages by day's work, but this was seldom. I have previously mentioned that the lack of desire to consolidate the mines was disadvantageous to mining in Guanajuato. On account of the *buscon* system it was not possible to handle the ore economically in any of the mines; each mine was opened by the *buscones* into small workings, entirely independent of the other. This explains the confusion in the old workings of the mines. When the production became so large that the mine could not amalgamate all its own ores, the same were sold, with those of the *buscones*, at public ore-sales (*rescates*) to the highest bidder. In these sales the weight of the ore-heaps was calculated by measurement with the eye and the value of the silver contained was determined by *tentadura* (or test). To obtain the *tentadura* they used the *jiacara*, a thin, light vessel, about 6 in. wide, varnished black on the inside and shaped like a hemisphere. The ore was first pounded and finely triturated between stones, washed, and the remaining small quantities of ore conveyed with clear water to the *jiacara*. The *jiacara* is held in the right hand and the ore loosened by slightly vibrating in the left hand, thus the silver ores arrange themselves (with the pure gold) in a bluish strip around the edge of the *jiacara*. The value of the silver and gold contained in an ore-pile is calculated by the color and size of this strip. As the result of much experience the miners can determine the value almost exactly with certain grades of ore. But there are many ores in the Veta Madre that are very rich, although they do not show any visible silver, that is, those peculiar double combinations of silver sulphide with iron sulphide do not show any silver in the *tentadura* although rich. Such ore was often not mined or thrown aside as waste.

"The money earned from the sales of ore, together with the silver returned from the *haciendas*, made up the whole production of the mines. The accounts of the mines were settled every Saturday, as at the present time; all salaries, wages, etc., were paid weekly. The weekly *memorias* was a list of all payments made by the mines; they included general expenses, wages, costs of handling the water, etc. (that is, the ores belonging to the *buscones* were not taken into account at all). The weekly profit or loss of the mine was found by subtracting the *memorias* from the stated silver production."

Next he describes the methods employed in taking water out of the mines. He tells of the hides sewn together so as to serve as buckets, and of the horse-whims or *malacates*, by the aid of which the Mexican was able to sink such deep shafts as the great pits of the Valenciana. He says:

"The system of controlling the water in the mines of Guanajuato, and in other parts of Mexico, will appear barbarous to a European, but it corresponds with the present standard of civilization in Mexico. The water is brought to the surface from depths of 600 m., in sacks (*botas*) of untanned skins, by means of *malacates*. Two cow-skins are laid together, hair outside, sewed tightly on the edges, so as to form an elliptical bag, which carries 18 to 32 cu. ft. of water. On the open end the

hides are stretched around an iron hoop, which gives an opening for bailing and discharging the water. The iron ring is fastened to the hoisting rope by leather straps. The shafts are not divided into compartments. To prevent excessive vibration the *botas* are made to glide on the sides of the shaft. A *bota* costs 11 pesos and lasts 3½ weeks. For hoisting ore to the surface and bailing water, only untanned calf-ropes of 1½ to 2½ in. diam. are used. These last for three months and cost 2½ reales or 30 centavos per running metre. The ropes run over rollers of mesquite-wood or of iron 60 cm. diam.; the rope drum is 5 m. diam. Three or four arms (each 8 to 9 m. long) are fixed on the vertical axis of the drum; three horses are harnessed to each of these arms. A speed of one metre of the rope corresponds to a speed of four metres of the horses. In hoisting the water from the Cata the speed of the rope was 80 cm. per second (December of last year), the speed of the horses being 3.6 m.; the horses ran in a continuous short gallop and were changed every four hours. A horse costs 20 pesos and lasts two years. Its maize and straw cost on an average daily 21 centavos."

In another part of the report he offers some general remarks concerning the development of mining in Mexico, and especially at Guanajuato. These are his words, translated from the German:

"Before New Spain was discovered, the natives knew the use of the several metals, such as gold, silver, copper, lead, and zinc (whether iron is doubtful). They understood how to win them not only from float and placers, but by vein mining. In the days of Montezuma the silver mines of Tasco, in the State of Coahuila, were worked; likewise the copper mines of Inguarán in the State of Michoacan. The Indians of New Granada and Peru were foremost in smelting ore; in the large cities of Anahuac, especially Azcapotzalco and Cholula, the art of manufacturing gold and silver vessels, etc., was highly developed. According to reports received by Humboldt, from Indians at Lican, silver ores were treated by melting them with a blast. Holes were dug and silver ore mixed with coal was thrown into them. Many Indians lay down around these holes, and blew in the necessary air through long bamboo pipes. The Spaniards brought their knowledge of mining to Mexico from the little attainable, in the 16th century, in Germany and other parts of Europe. A large industry developed. The statistic reports go back to 1690; from this time to the declaration of independence of Mexico, in 1822, the following amounts were minted:

Names of Mints.	Pesos.
1. Mexico, 1690-1822.....	1,640,493,784
2. Zacatecas, Dec. 11, 1810-1822.....	19,388,099
3. Guanajuato, 1812-1813 (end).....	992,803
4. Guadalajara, 1812-1822.....	2,990,033
5. Durango, 1811-1822.....	5,000,000
6. Sombretete, Oct. 16, 1810-1812, when it stopped work...	1,561,249
7. Chihuahua, 1811-1814, when work was suspended.....	3,603,660
Total from 1690 to 1822.....	1,674,033,491

"In connection with this it is probable that a certain part of the silver and gold production was exported in bars and was not minted in Mexico; but there are no reports of this.

"After the death of the Emperor Charles V., Spain exclusively influenced Mexico and tried to prevent all communication between New Spain and the rest of Europe. The improvements made in Germany, England, etc., in mining and amalgamation work, were not brought to Mexico. From the time of Charles V. to 1822 the Mexican miners did not learn anything from the European miners. Mining in Mexico at the close of the Spanish reign was on a lower rank than the German mining of the medieval times. The Mexicans must be

credited, however, with developing the amalgamation of ores; but even this branch is not fully developed to-day. It must be admitted that the Spanish Government tried eagerly to increase mining operations. By the decree of May 4, 1774, a society of competent miners was formed ("*el importante Cuerpo de la Minería de Nueva España*"), who were to study the same. At the same time a mining school was created in Mexico (*El Colegio de la Minería*) with large funds. This institute affected Mexican mining very much and would have regenerated it. During the Spanish domination mining was not at all influenced by the Government. The proprietors of the mines could operate their properties as they liked, and they did it in a barbarous manner; they worked their mines selfishly without any regard to the public welfare.

"In the war of independence the fanatical Mexicans destroyed all the Spanish acts, the good ones as well as the bad ones. The *Cuerpo de la Minería* existed in name only, and the mining school was deprived of all its funds. The first presidents of the Republic tried to repair the damages done during the war of independence and made wise provisions, such as lower taxes, no tax on quick-silver, free import of machines, patronage of foreign societies, etc. However, under the rapid change of governments not much was accomplished.

"Without the help of the Government, mining activities recovered by reason of the immense amount of capital brought to Mexico in 1820 to 1830 by foreign mining companies. I cannot understand, however, why these English and German companies lost their millions in but a few years. The mines could not have been the cause of it, for most of them yielded splendid results later, under more unfavorable political circumstances. Unfortunately at that time peculiar ideas were prevalent in Europe as to Mexico, where the Spaniards had won millions; the German and English miners thought they would find heaps of gold and silver. Everywhere expensive plants were erected; by the time the technical directors were persuaded that solid gold and silver is very seldom found and that it is not so easy to mine in the Mexican Cordilleras, far from civilization and without aid of proper tools and machines, and that all energy and endurance must be limited to a few single points, the capital of the companies became exhausted and the work deemed necessary could not be done. Several mines were left in the hands of a few officials who had become efficient in the service of the company; these mines were well managed and paid well. In such districts (especially where the Germans continued operations, namely, in Agangoo), mining was properly executed.

"The Anglo-Mexican Company in Guanajuato also worked in many other districts and brought undeserved discredit to mining in that locality, especially the large mine of Valencia. This company lost over a million pesos in Valenciana, Taca, Secho, and Mellado. All these mines have since paid well and in the future they will produce most of the silver minted yearly in Guanajuato; this company inaugurated the first steam engine in Guanajuato, but this machine, on account of its inefficiency, caused an aversion for steam-engines in that camp."

AMBER IN BURMA.—Burmese amber has a rich color, is hard, and takes a beautiful polish. It is mined in the most primitive way, as indeed is almost all kinds of mining done in that quaint country of rich resources. Usually amber mining is done by Burmese who have finished their harvest work and have nothing else to do. Small parties form and dig down near to where amber has been found. One man digs and another hauls up the dirt with ropes, each taking his turn at the bottom.

Mechanical Treatment of Gold Ore.

Written for the MINING AND SCIENTIFIC PRESS
By W. J. ADAMS.

Since 1898, when I published 'Hints on Amalgamation,' there have been many changes and improvements in the methods of working gold ore. The actual handling of the quicksilver, the cleansing of it, and the use of it in amalgamation, however, have not been improved, in the methods then and now in vogue; but the changes consist of mechanical improvements of all the machinery then in use, and most radical departures from old methods in the subsequent treatment of the tailing from the gold-saving plates. No new dressings or washes for plates are known, nor has any change in the types of concentrators been invented, except that of magnetic separation, and that of flotation.

Of the mechanical changes, there have been several in the standard type of battery construction. The Utica mortar increased the capacity of stamps from 3 to 5½ tons per 24 hours per head, by the addition of steel liners to the back and sides of the interior of the mortar, so that the shoes just have clearance.

Concrete mortar-blocks almost entirely replace wooden ones at the present time. The Standard mill will now also have mortars of low height, through the cover of which the 'boss' or stamp-head passes; the guides are iron or steel rings, the lower one just clearing the stamp-head; the stamps are hung up from the battery floor, either singly or as a whole by the turn of a lever; the cams do not require key-seats and can be released by the tap of a hammer; the pulleys can be unscrewed, or their hubs released in the same way as the cams; and the tappets are constructed on scientific principles, so that the bearing is all over the circumference of the stem.

Magnetic separation need only be mentioned, as it requires dry pulp, and probably a flaming roast; and is hardly applicable on the tailing of a wet-crushing mill. So far, in gold practice it has been employed only on deposits of black sand.

A process for separating the metallic sulphides was patented, using crude oil on the wet pulp, but was only feasible for a few ores, carrying slimed minerals. Then a process, employing an acid with the pulp, was also found adaptable to the flotation of minerals from their gangue. These two methods were combined, and in addition, the flotation was aided by a partial vacuum; and now it has been found of high efficiency on all ores requiring concentration, with a low working cost.

One very radical change has been made in the comminution of the sand. Previously the idea was to make the least possible amount of slime; now it is to grind all the pulp to slime, on account of the more complete extraction by cyanidation. Therefore, all the pulp, after the free gold is saved, is now reground. At first, tubemills were the only machines used, but their high first cost, expensive flint-pebbles, and the power required to run them, are now turning the attention of operators to other forms. Grinding-pans of the amalgamating type are more expensive in power and require outside screening, and their use has been abandoned. The Chilean mill has proved itself equal in capacity, cheaper to run, and with a more uniform product, as demonstrated in a competitive test at the Lluvia de Oro mine in Mexico. In fact, in many cases the subsequent cyaniding of the tailing has not been required, owing to the more complete amalgamation of all the free gold, and the sizing of the pulp, which insures complete separation of the metallic contents by the concentrators. A 10-ft. Chilean mill replaces 20 stamps, amalgamates even the rusty gold, as well as the flour gold; crushing all the ore, so

that 90% will pass through a screen with 100 holes per linear inch. It is cheaper to install than stamps, uses less than 5 hp. to run, requires little care, and has an exceedingly small loss in wear and tear.

Looking over the above, it is seen that there are now several processes of merit in place of the single one of the last decade. There is then no reason why any ore should be determined as too refractory and base for profitable treatment in these times. If you have a large deposit with low value in free gold, a matrix that is heavy, such as barite, for instance, use the vacuum flotation method. If you have a small mine, not capable of producing more than 100 tons per day, where the gold is fine or rusty, water is scarce, and power and freight expensive, use a Dodge breaker, crushing to ½ in., a Lane or Chilean mill, and belt-concentrators.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

The rock from Jerome, Ariz., marked J. C. S., is Serpentine.

The specimen marked M. M. Co., from Salt Lake City, is Granodiorite.

The specimen received from M. J. S. of Palomas, Ariz., No. 6 is Cuprite and Malachite in Quartz.

The three rocks from W. M. W., of Pine, Idaho, are from a pegmatite vein and contain oxidized Pyrite.

A specimen of slate, containing Galena, Calcite, and Sphalerite was sent by P. N. M., of Wallace, Idaho.

The mineral sample from Seatington, Cal., marked L. I. R., contains the black oxide of manganese with red rhodonite.

Rocks from Placer county, marked W. H., are: No. 1, Quartzite; No. 2, Hornblende Schist; No. 3, Quartzite; No. 4, Chlorite Schist.

The samples from Lucin, Utah, marked A. E. P., are: No. 1, silicious Magnetite; No. 2, Magnetite and Feldspar; No. 3, Hornblende Schist.

The specimen marked C. L. P. of Tombstone, Ariz., is a coarsely crystalline Limestone, stained with a black oxide of manganese. It probably owes its structure to metamorphism from some near-by volcanic intrusive.

Specimens sent by G. A. D., of Nelson, Nev., are: No. 1, impure Serpentine; No. 2, Serpentine Gouge; No. 3, Galena and Chalcopryrite; No. 4, Pyrite crystals in an altered porphyry. It shows no nickel mineral. No. 5, Feldspar Porphyry with Epidote.

The small pieces from Beatty, Nev., marked W. C. P., are: No. 1, Quartzite; No. 2, Albite; No. 3 and 4, Rhyolite; No. 5, Pitchstone; No. 6, red Hematite; No. 7, compact Chlorite; No. 8 and 9, Quartz Porphyry stained by Hematite; No. 10, Pitchstone.

E. W. S., of Landore, Idaho: Bromyrite and Embolite are two bromides of silver, occurring often in silver districts where the chlorite, cerargyrite is found. The silver mines of Mexico and Chile are well known occurrences. The brom-iodo-chloride, iodobromite is a rarer mineral.

Copper Converters, Hydraulically Operated.

By G. B. SHIPLEY.

*An interesting installation of copper converters is now being made by the Mammoth Copper Co. at Kennett, California, under the supervision of C. F. Moore, chief engineer. All of the machinery has been designed to meet the most exacting conditions.

The equipment consists of two hydraulically operated stands and eight shells, 96 in. diam. by 150 in. long.

Referring to the illustration, it will be noted that the shell at the top half has a peculiar shape, which is not

intense heat. In a great many converters, designed without the ribs, much trouble has been caused and a great deal of expense incurred in fitting re-lined shells into stands which have the air connections bolted to the heads.

For lifting the shells, there is riveted at the joint on the lower half a solid cast-steel reinforcing plate, which has cast integral with it one heavy lug on each plate, making four lifting lugs in all. These reinforcing plates or angles are also arranged for bolting on the top half by three extra heavy bolts on each side.

The pouring top is made of cast-steel and is parted on

found in other converters. The bottom half is 96 in. diam., and from the centre up to the joint both sides of the shell are formed in a tangent to a width at the top of about 7 ft. The object of this is to do away with the unnecessary curvature above the centre line to permit of a more secure lining being formed.

The parting joint between the bottom half and the top half of the shell is considerably higher than in other designs, the idea being to keep this just as high as possible and away from the extreme action of the molten copper; for it is a fact that in practically all of the barrel converters, with the exception of those at the plants of the Anaconda Copper Mining Co. and the Orford Copper Co., this joint is only carried a short distance above the centre line; and, since there is here no chance to ram the lining, it is only possible to form the joint with an adobe mixture. The result is that the joint is eaten away rapidly by the molten matte. In the new type of hydraulically turned converter, built by Allis-Chalmers Co., this vital defect has been overcome by raising the joint between the bottom and top shell.

The bottom section of the shell is made of flange-steel plate, which is reinforced longitudinally by four heavy T rails and rigidly secured at both ends to a solid cast-steel head provided with a riding ring cast integral with, and completely encircling, the head. Each head is spherical in shape and reinforced with eight heavy ribs to reduce expansion and contraction resulting from the

the longitudinal centre line, thus making this part in two interchangeable sections, which is an important feature when repairs are considered. In some cases operators are in favor of fitting the top with a short cast-iron pouring-nose, which can be removed and thrown away, when eaten up by the molten metal, and another substituted; whereas there are others who insist that the separate pouring-nose is objectionable, inasmuch as the additional flanges furnish places for accretions to form. With the top as shown in the illustration, it is only necessary to rivet a steel plate at the burnt-out portion. The shape of the top of this converter, as well as the bottom, is practically the same as that of the converters in use at

*Contributed by the Allis-Chalmers Company.

Anaconda. It is a peculiar shape which gives longer life to the lining.

The wind-box is rectangular in shape, and consists of a plain casting which lies close to the shell and underneath the riding-ring, thus permitting the shells to make a complete revolution and thereby do away with the stop that it has been customary to place on a great many riding rings in order to protect the wind-box and prevent the shell from turning too far. With the old stop-arrangements it was necessary to be very careful in turning; otherwise an operator might throw the shells off the stands, thus causing a serious accident.

Another feature of the self-contained wind-box is that it does away with the long flange and cover which has always been used where the air-valves or tuyeres were fitted on the inside of the wind-box. It is well known that there is always a great loss of air through the joint in the long cover ordinarily used, because the expansion and contraction and the hard service to which converters are subjected ruins the joint.

On each of the Mammoth Copper Co.'s converters there are fitted 16 Redpath individual tuyeres, having Dyblie ball-valves, and secured to the wind-box by swing-bolts. The discharge end of each valve, which is at right angles to the inlet, projects several inches inside the shell and through a cast-steel stuffing-box secured to the shell. This stuffing-box is bored out to suit the projection on the tuyere, and is arranged for holding asbestos packing, to prevent air-leaks, while the projection inside the shell is sufficient so that a lining of brick can be fitted around it.

Each tuyere is arranged so that the ball-valve and its seat are self-contained, and the valve can be quickly taken out and replaced by another. The pipe distance-piece is also independent and easily accessible. Therefore, it will be seen that with this individual arrangement of tuyeres, it is only necessary to disconnect two swing-bolts and pull out the tuyere; it is not necessary, when replacing a single defective pipe distance-piece, to disconnect a long and heavy cover and have the great difficulty of trying to make a joint on a long and warped casting. The opinion of many will probably be that accretions will form between the wind-box, tuyeres, and shell, to such an extent that it will not be possible to get at the swing-bolts which fasten the tuyeres to the wind-box; but this is not the case, because to obviate this there is an angle on top of the wind-box, which runs for the full length and is riveted to the shell.

It has been demonstrated that the ball-valve is more satisfactory than the roller or flap-valve, because the spherical shape of the ball adjusts itself to the valve-seat, leaving no chance for grooves to form, as a result of the hard usage and constant pounding of the tuyere punching-bar. On the air end of each shell, the cast-steel head is arranged to receive the end of the wind-box, which is fitted with a ball-joint concave flange, and receives the stationary air-nipple of the patented blast-connection.

This joint is especially adapted to converters and air-joints where it is not possible to bring flanges in line, by reason of the difference in centres of shells, which are bound to become distorted and lose part of their shape after hard usage. This connection consists of a cast-iron T, having the horizontal cylinder fitted with a ball-joint and piston. When the shell is moved into position the lever is pushed forward, and this moves the nipple into the concave flange on the head. The air is then turned on, and the pressure upon the piston holds the joint rigidly in place. This joint is superior to the old method of matching flanges, and has proved to be a great labor-saving device around converter-plants.

For turning the shell each stand is provided with a pressure-cylinder 18 in. diam., having a stroke of 7 ft.,

which is equivalent to turning shells 180°. The piston is fitted with four special metallic packing-rings, which are designed to obviate leakage, wear, and the expensive delays due to repairing soft packing.

The upper end of the cylinder is secured to a flange on the bottom of an A frame and at each end are bolted independent heads. The upper head is fitted with a brass neck bushing and a well proportioned stuffing-box. It will therefore be apparent that with this arrangement it is possible to take the piston and rod out through the top, which is a desirable feature.

The driving-stand is a solid cast-iron box section A frame with liberal bearing surface at base, which is arranged for securing to foundation with four 1½-in. bolts. The upper portion of this driving-frame is designed to receive the turning mechanism, which consists of a cast-steel rack and cast-steel shrouded spur-gear. The rack is connected at the lower end to the piston, and opposite to centre line of shaft at the upper end a guide is arranged, with a well proportioned sliding surface. Thus it will be seen that the turning motion is transferred from the piston and rack to the gear.

The gear is keyed to a hollow-steel shaft which has fitted to its driving end a universal coupling, arranged so that the shells will rest true on the rollers and that at the same time the drive will adjust itself to suit the alignment, thus avoiding any undue strains on the driving-shaft. On the head of the shell is a groove, which matches a tongue on the universal drive; the main gear is turned around until the tongue is vertical, when the shell is placed, and there is clearance enough on each side of the tongue for keys, which are tapped into place by a light hammer, thus holding the shell rigid to the universal connection.

In some converters this groove on the shell has only sufficient clearance to allow the shell to drop over the tongue, and no provision is made for using the keys, in which case there is danger of a back lash, due to the clearance and the fact that the piston will have a chance to accelerate before it picks up the shell, the result being a severe shock, detrimental to the gears.

There is a sheet steel housing for each frame, which covers the driving gear to prevent dirt from getting into the operating parts.

An important detail in connection with the pouring of a converter is to obviate spatter or spilling of the copper upon the floor, and to prevent this there is furnished, when requested, a Bennetts' pouring spoon, hung on a steel arm on one side of the roller-stand as may be seen from the cut, with the arm so arranged that the spoon can be adjusted to suit the pour of copper from the shell and the position of the molds which rest on the truck directly underneath.

The following data in relation to these converters will be of interest:

Weight of shell.....	19 tons
Weight of lining	44 "
Total.....	63 tons
Concrete in foundation.....	1,200 cu. ft.
Capacity of charge.....	40½ matle
First charge (new lining).....	8.25 tons
Average charge.....	10.00 "
Maximum charge.....	14 to 16 "
Air-blast pressure.....	12 to 15 lb.

Assuming six charges per stand per 24 hours, and 26 working days per month, the capacity of each 96 by 150-in. converter will be about 1,250,000 lb. copper per month. Of course, this will all depend upon the matte and the conditions under which the converter is operating.

C. H. Repath, engineer of the Anaconda Copper Mining Co., F. E. Marcy, of Salt Lake, J. A. Dyblie, and B. H. Bennetts, all deserve special mention for the many features incorporated in this specially designed converter.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

DUMPING-CAGE FOR MINE-CARS.—No. 864,813; George Trotter, Riverton, Illinois.

The combination of stationary channel plates having upwardly inclined ways adapted to accommodate wheels traveling in said ways, and horizontal ways communicating with said inclined ways and adapted to support wheels running within said inclined ways, a vertically movable cage, a track on said cage, a platform traveling on said track and adapted to tilt at the limit of its forward movement, wheels connected with said platform and adapted to travel in the inclined ways of said channel plates and adapted to support the front end of the tilted platform when said wheels are in the horizontal ways of said channel plates, means for connecting the ear with said platform, platform-locking devices adapted to lock said platform in horizontal position, and means for releasing the platform-locking devices immediately before the wheels on the front end of the platform enter the inclined ways of said channel plates, and again automatically locking the platform immediately after the withdrawal of said last named wheels from the inclined ways in said channel plates.

MEANS FOR PREVENTING ESCAPE OF UNFUSED ORE FROM SMELTING CONVERTERS.—No. 864,719; Ralph Baggaley, Pittsburg, Pa., Charles M. Allen, Lo Lo, Mont., and Edward W. Lindquist, Chicago, Ill.; said Allen and said Lindquist assignors to said Baggaley.

A smelting converter in which the smelting is effected by the heat of oxidation of the ore charge having tuyeres, a constantly open over-flow at one end, and a bridge or barrier placed near said opening and arranged to check floating particles of ore and submerge them in the molten bath in their movement toward said opening.

ORE-CONCENTRATING JIG.—No. 864,776; Henry Foust, Baxter Springs, Kansas.

In combination, ore cells, a mesh in each of the cells, a converging bottom positioned beneath the cells, a valve casing supported by each of the meshes and held a distance thereabove, discharge pipes leading from within the valve casings to the exterior of the cells, a valve within each casing resting on the discharge pipe thereof, and means on both sides of the cell acting in conjunction with the converging bottom for forcing a liquid through the meshes.

PROCESS OF SMELTING ORE AND CONVERTING MATTE.—No. 865,333; Arthur M. Day, Bingham Canyon, Utah.

The process of smelting ore and converting matte, consisting in forcing air into the charge and injecting powdered silica or silicious material in a fluent form through one or more tuyeres with an air-blast separate and distinct from the air supply to either tuyeres.

APPARATUS FOR CONCENTRATING ORES.—No. 865,334; Alexander S. Elmore, London, England, assignor to The Ore Concentration Co. (1905), Ltd., London, England.

Apparatus for the treatment of ores with oil, comprising a mixing tank, a mixing device for intimately mixing a pulp of the ore with oil in the mixing tank, and a floating seal of oil inclosed by a ring for excluding air from the said tank during the mixing process.

Books Received.

'The Metallurgy of the Common Metals: Gold, Silver, Copper, Lead, and Zinc,' by Leonard S. Austin, Professor of Metallurgy and Ore-Dressing, Michigan College of Mines. First Edition, 1907: MINING AND SCIENTIFIC PRESS, San Francisco. 407 pp. Price \$4.

Since Tubal-Cain instructed "every artificer in brass and iron," there have been two kinds of books on metallurgy: Those attempted by half-informed tyros, and books written by men who know. This book is written by a man who knows. If he had never heard of the great school of mines at Houghton, or if the able author, who has himself contributed not a little to the progress of the art, the reader would know at first glance that this book is far and beyond the common run of metallurgical manuals.

In the first place, a good teacher of metallurgy is a rare product. He should know the theory but he must know the practice; and that means more than the few weeks of a summer vacation spent in watching others in the overalls. The metallurgist is the man who has won metals himself; the man who has met and conquered the constant challenge and corrective of business responsibility in the long and bitter task of making the ore pay for its own dressing and smelting. Professor Austin knows this, for he has done it; and his book, in every line, modestly but surely, certifies its own genuineness. The frank but terse preface tells that Professor Austin knows silver, lead, and copper from his own "practical work." That is the standpoint. It is not given to any one man to know it all; but this book is one that knows one side thoroughly. The reference to the revision of the parts of cyaniding by Mr. Bosqui enhances its value, and is only an incidental evidence of the straightforwardness of the whole treatise.

The book is primarily a textbook; but it is no borrowed abstracting of alien or unfamiliar material. This 'Metallurgy of the Common Metals' carries a clean compact outline of the general principles of the art; but all this is broadened and strengthened by constant and timely reference to the latest practice. We note the data for the calculation of furnace charges for lead, copper, and iron, the well valued cost-charges for construction and operation; and we note also some omissions which the cautious critic may well ascribe not to the oversight of the author, but to his desire to present a conservative balance of safe practice. To be sure, some subjects, as zinc, might have had a more generous space; there are the few and exasperating "errors of the first edition"—probably more annoying to the author than to anyone else; there is but scant space given to that young giant, the gas-producer (may we note that the thermal value of carbon monoxide is about as valuable as that of hydrogen itself)—the list might be indefinitely extended—but on the whole, Professor Austin has given us an invaluable digest of metallurgy in good perspective and up to date in wise business practice.

Of course, this book will at once be compared with the older textbooks and manuals; with the ambitious and often helpful Schnabel; with Hofmann on copper and lead; with Peters on copper; with Campbell on iron and steel, and with Roberts-Austen's series. With each and all of these, this book of Professor Austin holds its own, in its way and for its purpose; for it is written by a man who knows lead and copper from the practical business standpoint. There may be plenty of men who know as much as Professor Austin, even in his own line; and the modest and genuine author would be the first to acknowledge it; but the practical man rarely has the time to write such rare treatises as this is; he has not done it, he will not do it; therefore, our greater debt to Professor Austin; and the greater value of his book as compared with more pretentious manuals.

But there is one omission to which we revert with deep regret; every good book of this sort should have a good index. This book is primarily a textbook; but it will prove of great value to the old metallurgist to whom it comes in the distraction of dust and sweat and worry. This metallurgist is always a busy man, often a tired man; remember him and be patient with him. He may not always have

time or strength to search through the clear but fragmentary table of contents for the tables of costs or charges, the diagrams, the geographical helps, the hundreds of helpful facts that are sprinkled so generously through this volume. The suggestion is made with great caution, but we believe it is wise. The lack of an index would not be felt so keenly in a poor book. But Professor Austin has put the whole profession under great obligation; and, as we thank and congratulate him, we also thank and congratulate the MINING AND SCIENTIFIC PRESS for this worthy sample of bookmaking.

C. S. P.

Commercial Paragraphs.

THE MOORE & SCOTT IRON WORKS has been awarded the contract for overhauling the Mexican steamer St. Denis, bids for which were recently opened. The contract includes oil-fuel installation and complete new floors and frames under boilers and engines.

GEO. W. MYERS, for many years the Pacific Coast representative of the Chrome Steel Works, of Chrome, New Jersey, announces his return to San Francisco from temporary quarters in Berkeley. He will occupy the same offices as before the fire, 724 Kohl Building.

THE INDEPENDENT SUPPLY CO., of Napa, California, reports orders for their Maryland Georges Creek blacksmith coal from the Union Iron Works Co., Risdon Iron Works, Joshua Hendy Machine Works, Western Iron Works, and the United Railroads. For the few weeks that they have been in this field with their Eastern products they have been unusually successful and desire to call the attention of the Western mine managers to their smithing coal and invite their inquiries.

ONE of the two Allis-Chalmers 32 by 72-in. direct acting Corliss hoisting engines, purchased some months ago by the Boston & Montana Mining Co., is being erected in a building designed for the purpose close to the Tramway shaft, near Butte, for the joint use of the Rarus Tramway, Minnie Healy properties, and the Red Metal Co. The machine is a duplicate of the hoist recently installed at the Pennsylvania mine. It is of the first-motion type, weighing approximately 230 tons, fitted with automatic cut-off gear and governor, and also with complete steam reversing gear. The hoists will have a lifting capacity of 34,000 lb. per trip, from a depth of 3,500 ft. They will operate at 149 lb. steam pressure. This load includes the weight of the rope, which is over 10 tons. When working regularly at full capacity, the engines will develop approximately 2,500 hp. These hoists will be required to make from six to seven trips per hour, both night and day. While the ore from the Rarus property will be hoisted, as heretofore, through the Rarus shaft, the ore from the Minnie Healy will be lifted through the Tramway shaft—an arrangement found for the present to be most economical. From the Tramway shaft the ore will be dumped into temporary bins of 50 tons capacity, and from these, in turn, the ore will be taken by motor-drawn cars to the railway bins, which will have a capacity of 3,000 tons. The ore will be brought to the surface in skips. The Tramway shaft is now down 1,000 ft., and another 1,000 ft. will be sunk as soon as the new plant is in operation. The Rarus shaft is 1,800 ft. deep, and at the latter depth a station is being cut.

Catalogues Received.

THE CYCLONE DRILL CO., of Orrville, Ohio, has issued an artistic little booklet entitled 'Cores,' describing and illustrating its line of core-drills and combination machines handling core, hollow rod, and cable tools, and containing some valuable information relative to their operation, construction, and design.

THE J. GEO. LEYNER ENGINEERING WORKS CO., is mailing Bulletin No. 512 on the 'Model 6 Water Leyner Drill.' This is their latest type of large rock-drill, in which the number of parts has been materially reduced, and at the same time strengthened, giving the machine a longer life and reducing the cost of repair.

Editorial.

OUR HONORED CONTEMPORARY *The Canadian Mining Journal* is doing a useful work in throwing the fierce light of truth on some shady mining promotions in Ontario. The activity of prospectors in that part of the Dominion has been made the cloak for much feline finance. We wish the *Journal* success in its public-spirited endeavors.

FINANCIAL CONDITIONS at London, especially as regards mining, are gloomy. Bankers are curtail- ing credits, in the expectation of a monetary crisis in October. Everyone is trying to liquidate, this being the logical result of the great absorption of capital in new enterprises all over the world during the last three or four years. But industrial conditions are not radically bad and the speculative public will recover a normal tone after a little physic.

WE HAVE RECEIVED a letter commending the list of recent papers and books on mining and metallurgy that appears in the monthly bulletin of the Institution of Mining and Metallurgy. The commendation is well deserved. Such indexes are convenient and useful. Several of our contemporaries print something of the kind, but the value of them is greatly lessened by the fact that they are incomplete, and not always judiciously selected. In the meanwhile, with the help of the earnest men of the profession, we hope to publish the articles for the other fellows to index.

DESCRIPTIONS of celebrated mines, stating their geological structure and the mining methods employed, are always of value, and when they are written by the managers themselves, articles of this kind possess an additional interest. Such is the contribution on the Combination mine, at Goldfield, Nevada, written by Mr. Edgar Collins, who was manager until recently, when he became superintendent of the Montana-Tonopah mine in the neighboring district of Tonopah. The Cornish say: "A good bal makes a good captain," the last word being abbreviated to "cap'n." Conversely, a good captain can make the best of the opportunity to develop a highly successful mine. At Goldfield the combination was a fact as well as a name.

THE DAILY PRESS makes a lovely fricassee of geological information whenever it tries to be technical. For instance, it is stated in a San Francisco paper that: "A trench averaging five feet in depth and 100 feet long has exposed a huge quartz ledge with a hyperite capping fully forty-five feet wide, flanked on the west by a black basalt dyke and on the east by a vast deposit of lode porphyry, thus embracing perfect geologi-

cal conditions for a wonderfully rich gold mine." Of course, 'hyperite' is highly indicative of rich ore and a black basalt dike is a sure thing in the way of favorable rock formation, but not nearly so useful as an argillo-arenaceous matrix of a tufaceous character, sprinkled with a metasomatic replacement and peppered all over with the highly indurated remnants of the Paleozoic age. That is what you want; and then to be sure that there is the making of a good mine, ascertain how much gold there is in an average ton of the 45 feet of quartz.

The Price of Copper.

COPPER is having a sinister influence on the stock market because a noteworthy portion of the recent speculative debauch took the form of gambling in copper mining shares. We are now having the reaction. Apart from this, a collapse in the price of the metal was bound to come in consequence of the wholly irrational attempts to peg copper at a price determined by one or two metal-selling agencies. This has been tried before, with like results. During the European trade reaction in 1891 the Amalgamated people tried to keep copper at 17 cents, only to find that the law of supply and demand was too much for them; they resembled Mrs. Partington, who tried to mop the incoming tide. Much in the same way and with the same spirit, in the early part of this year, copper was 'marked up' by a handful of metal speculators to 25 cents; when the production began to increase faster than the consumption, they refused to budge until the market ran away from them, so that in August the price was put at 18 cents. Just before this was done H. H. Rogers of the Amalgamated Company had made a public statement that the price was "fixed" at 22 cents. At that date, not two months ago, Phelps, Dodge & Co. were quoted as saying that 18 cents was a bedrock price and that the market would strengthen. The *Paris Temps* said oracularly that the price of the metal "is not likely to fall below £80 per ton," this being the equivalent of 18 cents per pound. The *Economiste Française* echoed this assertion. Meanwhile excessive speculation all over the world caused a temporary financial stringency, preventing the expansion of enterprise and causing a decrease in the demand for the metal. This economic fact made the metal authorities look foolish. Unable any longer to stem the tide, the Amalgamated sold a lot of metal at 15 cents when it was quoted at about 17, and, finally realizing the condition of the market, the directors ordered a curtailment of production at the mines. The daily press stated that the mines at Butte were to be closed down, but this, of course, was an exaggeration, for to close all the mines of the Amalgamated would ruin the State of Montana and create a disaster of the first magnitude. Nor would it restore the balance, for the trouble is not so much with an excessive production of the metal as the accumulation of stock due to a mulish insistence on a price not warranted by the condition of business. Even at 15 cents the Amalgamated will make a profit, although it may not pay all the dividends expected on an inflated capitalization. It costs

12½ cents per pound to produce copper at Butte. Similarly Calumet & Hecla has decreased its quarterly dividend from \$20 to \$15. As it produces 94,000,000 lb. per annum at 8½ cents per pound, there is still a lordly profit. This is also true of Wolverine, which produces 9,000,000 lb. per annum at a cost of 7½ cents per pound, and has been the excuse for a big speculation, unmindful of the limited, though large, reserves of ore and oblivious of any such considerations as are involved in the amortization of capital.

The cost of producing copper has risen 2½ cents, or even more in places, during the last three years, by reason of the increased cost of materials and the demands of labor. Insufficiency of labor, scarcity of coke, and bad railroad management have all tended to hinder economic operations at the mines and smelters. Allowing for the shorter shift, the lesser efficiency, and the growing desire to do as little as possible for their pay, the miners are paid almost double the wages of a few years ago. Thus while the price of the metal may fluctuate, the cost of production in many cases increases steadily, despite the application of technical skill, metallurgical invention, and business sagacity.

The world's production of copper in 1906 was 715,000 tons, as compared to 700,000 tons in 1905. The normal increase is 8 per cent per annum. Expanding industry made big demands on the supply and this led to a rapid rise in the price of the metal, so that in January 1902 it was 11¼ cents and in March 1907 it was 25¼. This violent rise was due in part to economic conditions but in its extreme phase it was directly traceable to manipulation, that is, an effort to create a scarcity by withholding supplies in the expectation of forcing consumers to pay a maximum price. During the first half of 1907 the buyers and sellers kept apart, they tried to bluff each other, and the buyer got the best of it, because industrial exuberance began to wane in consequence of exorbitant demands on the resources of capital, while concurrently the slowly increasing output of copper finally produced a surplus fatal to any attempt to 'fix' the price of the metal. At the beginning of September there were about 150,000,000 pounds of unsold copper, refined and ready for consumption, as against about 10,000,000 pounds at the end of 1906. This unmanufactured copper, instead of being in the warehouses of the consumers, was on the hands of the producers. Consumers had depleted their stocks in the effort to force the producers to climb down from unwarrantable prices and they had succeeded in forcing the producers to lessen the quotation. So the price tobogganed from 25¼ in March to 14¼ last week. A collapse in the market for railroad securities, due in part to over-speculation, and in part to the Government's effort to curb corruption, caused a drain on the banks and this in turn deterred consumers from buying copper or any other supplies until the monetary conditions eased. Then came the fall in the shares of copper mining companies, until finally the different factors forced several copper mines to close down and led the directors of others to give orders for a radical curtailment of production. This is having a good

effect already. As financial conditions improve the consumers will take the copper accumulated in the hands of producers and the price of the metal will become normal, that is, it will be governed neither by panicky conditions nor by an impudent effort to fix it on the dictum of a metal-selling agency, but by the fluctuations of supply and demand. It ought to rise slowly until it reaches, say, 18 cents. But there is one factor that may cause a further recession and that is the action of the Standard Oil coterie, now under examination by the Government. These men are as anti-social as Malay pirates and as unscrupulous as San Francisco supervisors. If the prosecution now under way should drive them to the wall, they may create a panic in order to render public opinion less eager to encourage a legal pursuit. The effective portion of the community holds shares or bonds to a varying degree. Most of them are willing to see the law enforced, if it does not touch their pocket nerve. When that happens, they wince. This may be worked to the advantage of Rockefeller, Rogers, and the rest of the buccaneers. In the confusion thus created, industry would suffer, the demand for copper diminish, the price recede even to 10 or 12 cents per pound. Modern civilization is complex.

The Geology of Leadville.

IT IS PLEASANT TO TURN from the financial bog to the mountain tops of science. Assuredly if anyone wishes to breathe the strong clear air of the upper ranges of human thought, he can do so by reading the five pages we devote in this issue to an abstract from the report of the Geological Survey on 'The Downtown District of Leadville, Colorado.' It is more than a geological report on a great mining district, it is the vindication—hardly needed—of a splendid reputation and the coping stone of a nobly useful career. We have no doubt whatever as to the spirit with which this contribution to geological knowledge will be received. That large part of the mining profession which is interested in geology as applied to the exploitation of ore deposits will read the well balanced essay of Mr. S. F. Emmons with keen pleasure, and with a glad appreciation of the service he has done to Leadville in particular, and to American mining in general. Twenty-five years ago, after accomplishing a wide range of exploration in association with Clarence King and other geological pioneers, Mr. Emmons, then in the prime of manhood, undertook to decipher the complicated structure of the Leadville region. In 1882 his first report was issued, and in 1886 the monograph on Leadville appeared. It is not too much to say that this monograph was then, is now, and is likely to be for many years to come, the model for the type of treatise devoted to the economic geology of a single district. The elaborate maps have been tested by a generation of energetic miners only to become the better trusted. The illuminating explanation of the rock structure of a complex bit of the earth's exterior has been a guide to the managers of mines and a light to students of geology for 25 years. It is certain that even

as measured in the commoner unit, the monetary worth of that monograph reaches several millions of dollars, for to such an extent did it aid the search for valuable ore.

At the time of the preliminary report, the conservative statements of Mr. Emmons elicited protest from the more optimistic exploiters of Leadville's bonanzas, and objection was made to some of his views because they did not accord with the flamboyant expectations of the promoter. It was left to Alden Smith to create a cairn for his own scientific sepulture, but in 1882 the cairn was mistaken for a beacon. Between 1886 and 1890, excellent papers on Leadville were published in the Transactions of the American Institute by F. T. Freeland, C. M. Rolker, and A. A. Blow. These gave supplementary data and offered criticisms upon the work of Emmons. Finally, Posepny, in 1893, made some objections founded mainly on the misunderstandings of previous critics, the general trend of which was to impute to Emmons a narrow theory, namely, that the overlying porphyry was the source of the metals, and that Leadville was an example of ore deposition by descending solutions. As a supplementary investigation was in progress and a second report was in course of preparation, Mr. Emmons deferred his final reply to these and other criticisms. It was a fine example of a quality rare in these days of hurry—a patience that awaits the accumulation of the necessary facts. Not everyone will wait twenty years to refute his critics, nor is it given to many to be able at the end of such a period to hold the attention of his audience. Fortunately Leadville is still an important mining area, and apart from this economic condition the general interest in the theory of ore deposits has increased enormously since Monograph XIV appeared, so that for every one interested in the subject at that time there are at least a score today. And this is due in no small degree to the writer of that monograph, for his geological papers, such as 'Structural Relations of Ore Deposits,' 'On the Origin of Fissure Veins,' 'The Secondary Enrichment of Ore Deposits,' have taught a generation of mining engineers how to apply geology to the search for ore. Happily the knowledge, continental in its scope, of a thorough student of nature has been joined to a rare faculty for writing clearly, and to an instinct for the truth that has illumined the dark places of philosophic inquiry. Nor have exceptional opportunities for acquiring information led to arbitrary dicta such as kill discussion. In this respect Mr. Emmons has furthered the ventilation of new ideas and encouraged the work of younger men. The reply to his critics appearing in the Downtown Report is scholarly, for it succeeds in being both penetrating and polite. We recommend it to the imitation of the young men in the profession as a model of scientific discussion, correcting errors while affording new information, giving credit to the good points of another man's comment, while defending the accuracy of his own deductions. Leadville has given us more than its many million dollars worth of gold, silver, lead, copper, and zinc; it gave us a great geologist.

Personal.

J. R. FINLAY is in Montana.
 J. H. CURLE is at Broken Hill.
 CHARLES BUTTERS is at New York.
 E. G. SPILSBURY is on his way to Mexico.
 CURTIS H. LINDLEY has returned from Nevada.
 F. W. BRADLEY has returned from Idaho and Alaska.
 L. M. B. BULLOCK is at Halifax, on a visit to his home.
 J. POWER HUTCHINS is here, on his return from Alaska.
 BEN. S. REVETT is at Callahan, in Siskiyou county, California.

L. PARRY has gone to Russia, to take charge of a copper smelter.

LOUIS J. ABRAHAM has returned to London from Toronto.

W. FISCHER WILKINSON is at the Camp Bird mine, in Colorado.

F. L. COWARD has returned to Bronson, Mich., from Colorado.

W. R. FELDTMANN has returned to London from Western Australia.

E. N. ENGELHARDT has been appointed superintendent of the Selby smelter.

JOHN W. MERCER was in San Francisco on his way to the Colorado river.

ROBERT B. TODD is manager of several mines in the Goldfield district, Nevada.

FRANK W. OLDFIELD is investigating copper prospects in southern California.

C. O'BRIEN has gone from Oakland to Yreka, in Siskiyou county, California.

VICTOR G. HILLS, of Denver, is at Guanajuato, Mexico, making a mine examination.

ALFRED VON DER ROPP is expected in San Francisco on his return from Europe.

S. W. OSGOOD, of Chicago, has been examining the mines and mill of the Gould Mines Co. in Montana.

C. L. BUCKINGHAM is general manager for the Kimberley-Wilfley Mining Co. at Kokomo, Colorado.

JOHN A. BURGESS, who is with the Tonopah Mining Co., was married at Berkeley on September 25.

JOS. C. HOPPER is returning from England to San Francisco. He sailed from Liverpool on the *Majestic*.

W. A. CALDECOTT, consulting metallurgist to the Consolidated Goldfields of South Africa, is in San Francisco.

NORMAN W. PARLEE has resigned as superintendent for the Ivanpah Con. Mining Co.; he is now at Los Angeles.

EDWARD L. DUFOURCO, of New York, is general manager for the Minas Pedrazzina Co. in Sonora, Mexico; and he is there now.

FRANK PERRY, manager of the Creston Colorado and Grand Central mines, at Prietas, in Sonora, Mexico, is on a visit to New York.

C. M. FUELLER has returned to Denver from Birmingham, Alabama, and is now doing professional work at Telluride, Colorado.

THOS. A. VARDEN, of Sacramento, and JNO M. DAUGHTERTY, of Omaha, both of the American Mining & Development Co., are at Salt Lake City.

J. M. CALLOW, of the General Engineering Co., is engaged in professional work in Arizona and Mexico. He will return to Salt Lake at the end of October.

C. H. LIVINGSTONE has resigned as smelter superintendent for the Selby Smelting & Lead Co., and will visit his home at Denver before taking a position at Monterrey, Mexico.

J. H. BAKER, formerly with the United Verde Copper Co. of Jerome, Ariz., and the Old Dominion Copper Co. of Globe, Ariz., is at present superintendent of the California & Nevada Copper Co., at Daulton, California.

General Mining News.

ALASKA.

A shipment of 650 tons of ore has been made from the Standard copper mine, at Landlock bay. Work was begun on this property about 18 months ago by James A. Bourke and John L. Steele of Valdez. The company is a close corporation, financed by the employees of the American Bank Note Co. of New York. A wharf, ore-bunkers, buildings, and a 3,500-ft. aerial tramway have been built and the little mine is well equipped. The property is situated 10 miles east of Ellamar, and 40 miles from Valdez.—The annual meeting of the stockholders of the Alaska Copper Co. has been held in Seattle. Pittsburg shareholders submitted a plan for reorganization, and asked for a new board of trustees to manage the affairs of the company. The proposal was adopted. The new trustees are: A. P. Burehfield, H. W. Armstrong, H. Bryson, F. C. Lane, G. L. Bond, and W. J. Post, of Pittsburg; S. H. Moore, of New York; H. T. Granger, of Seattle; and S. L. Wood, of San Diego.—A large number of laborers are coming out from Dawson, and many of them have already reached Whitehorse. An attempt will be made to induce these men to remain in the Gastineau camps, where there is a shortage of men, and where good wages prevail.

It is reported that the Guggenheims have closed down all their work in the Klondike for the winter, and will attempt to send all their employees to the Copper River country to work on railroad construction. One or two dredges are still operating, but the Atlin work has just stopped and the 170 men are out of employment, making over 1,800 idle men in the Klondike camp, most of whom are coming out at once.

ARIZONA.

COCHISE COUNTY.

A station is being cut at the 1,300-ft. point in the shaft of the Denn-Arizona, at Bisbee, and sinking has been stopped. A drift will be started to the southeast. The compressor transferred from the Shattuck is working, and oil instead of coal will be used as fuel at the power-plant.—The Shattuck-Arizona continues to ship 400 tons of ore per day, coming principally from the 700, 800, and 900-ft. levels. The winze from the 800 level of the Leo claim continues in good ore. The new compressor is supplying 15 drills underground.—The Wolverine & Arizona tunnel from the Higgins has run out of the ore and into altered limestone again, and it is possible that driving will be discontinued and work confined to the ore.—The shaft of the North Bisbee Development Co. has been retimbered and work started again; sinking, and driving the tunnel.—Most of the Superior & Pittsburg ore is coming through the Cole shaft, and there has been a slight increase in production from this shaft as well as from the Lake Superior & Pittsburg and Junction shafts.—The Copper Queen company is making no attempt at increased production, and is pushing work on the drifts toward the Sacramento shaft.

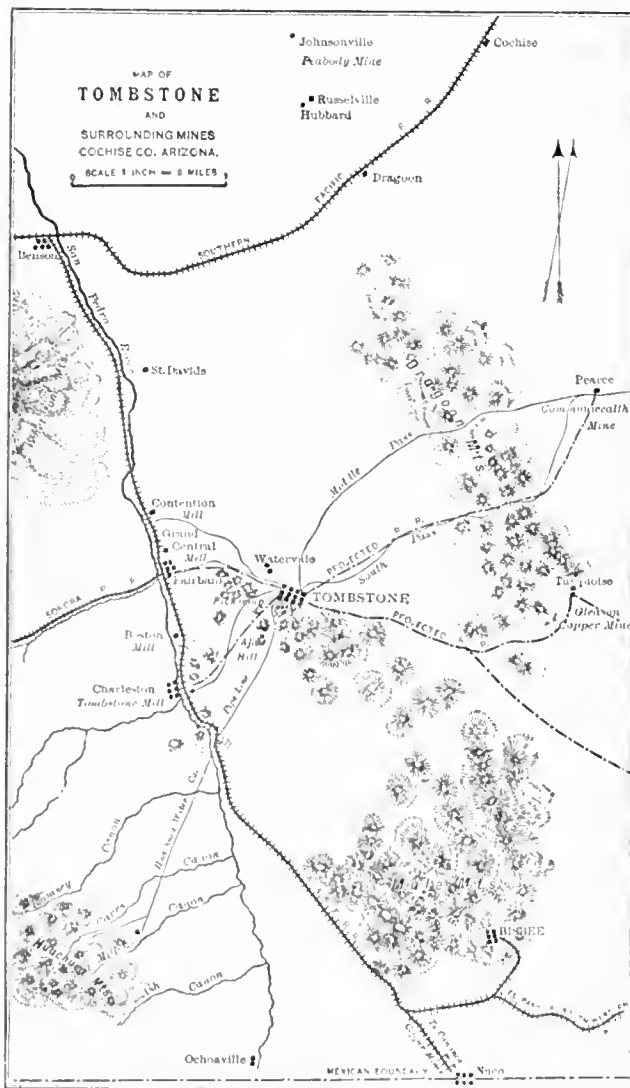

GILA COUNTY.

Five furnaces have been working at the Old Dominion smelter, making over 100,000 lb. copper per day. The cross-cut in block No. 6 on level 14 has encountered sulphide vein No. 2, while the winze from the level has reached a depth of 1,770 ft. A cross-cut will reach sulphide vein No. 1 by Oct. 30. The condition of the mine is good and 35,000 tons of coke are on hand at the smelter.—The Superior & Boston company has arranged with the Arizona Commercial Co. to start a drift on the 500-ft. level of the Blackhawk mine to develop the Great Eastern claim of the former company. The Great Eastern shaft will reach the 426-ft. point in a few days, corresponding to the 500 level of the Black Hawk, and they will be connected to aid ventilation. Sinking continues in the limestone shaft, which is down 290 ft. The drift on the 220-ft. level is still in ore. The southwest drift in the Black Oxide is in carbonate ore, 500 tons of which are on the dump.—The Arizona Commercial Co. is working 150 men. From the Copper Hill, 100 tons per day of siliceous ore is shipped, and some stoping is being done on the

500-ft. level.—While driving on No. 3 sulphide vein on the 13th level of the Old Dominion, a streak of ore was encountered that is believed to be the highest grade copper ore ever discovered in the district. While the streak is only about a foot wide, some samples taken from it assayed as high as 70% and the shoot will average in the vicinity of 40%. The ore is both glance and native copper. Another strike of native copper was reported from the mine of the Arizona National company on Lower Pinto creek.

MOHAVE COUNTY.

The Cerbat Mountain M. Co. is about to try the leasing system on the Vanderbilt mine, and hereafter all the company's mining operations will be confined to the Idaho and other properties. In the Vanderbilt the company has a large amount of ore blocked out. This piece of ground is to be let to tributors on a royalty system, while the other

Southeastern Arizona.

parts of the mine are to be let at a lower rate of tribute. The company is operating its mill at Cerbat.

PINAL COUNTY.

The Madeline shaft on the Big Lead property at Ray has reached a depth of 300 ft., and has penetrated the zone of secondary enrichment. W. B. Twitchell, the superintendent, is having a trestle constructed across Copper canyon for a ear-track from the Madeline shaft to the concentrating plant of the old Kelvin Reduction Co., so that the mill can be operated on ore from this shaft. This plant will handle as much ore as does the Big Lead mill, hence inside of a few weeks the company will be milling 100 tons of ore per day and may then soon reach the dividend-paying period.

YAVAPAI COUNTY.

(Special Correspondence).—Encouraging reports of progress at the Alaska mine at Congress are heard from reliable sources. The mine is situated 2,500 ft. south of the Congress

mine, from which much ore has been stoped. The Alaska is a gold mine. Two shafts are being sunk on a vein parallel with the Congress vein. The mine was examined two years ago by Chicago engineers, who pronounced the property a good one. A test of 200 tons of ore ran \$30 per ton in gold. There are no base metals in the ore, making it easy to cyanide. The company is enthusiastic over the future of the property. The formation is similar to that of the other mine and there is every indication that the vein will go to a great depth. The Congress mine is down 4,000 ft. A new orebody has been struck in the Alaska in the past few months and more extensive operations will begin this fall. New machinery has been ordered and by April the company hopes to have in a 10-stamp mill. There are 1,000 tons of ore on the dump. The two shafts are down 400 ft. and 1,200 ft. of driving has been done. All the work has been in ore, and the vein is two feet wide. The company is backed by Eastern capital.

Phoenix, Sept. 20.

A body of gold-bearing ore was recently opened in the 500-ft. level of the King Solomon. The new find is a continuation of an ore-shoot, the longest ever opened in the mine. The pay-streak is the entire width of the drift. The drift is being pushed ahead and a cross-cut will be run to the hanging wall later to determine the size of the deposit. —On the Burrage claim, adjoining the King Solomon group, F. X. O'Brien is having a hoist installed at a 500-ft. shaft, which will be unwatered. Drifts will be run on the vein at the 500-ft. level. —At the camp of the Lookout Copper Co., in the Slate Creek district, the work of installing the new boiler and hoist recently delivered is being pushed, and the company will develop its holdings on a larger scale than ever before. Contracts for 1,000 cords of wood have been let, to be delivered as soon as possible. New buildings are being erected to accommodate the large force of miners that will later be employed. —The Buffalo-Arizona Mining Co. has a force of mechanics installing a cyanide plant at the 5-stamp mill and will develop the Parker group of mines, recently taken under bond from S. A. Parker. The group of 18 claims is situated on the east side of Turkey creek, about two miles by wagon-road from Turkey station, on the Bradshaw Mtn. The locations cover a series of gold-bearing veins, which have been developed by Parker during the past three years. He installed a five-stamp mill on the ground, where the output was treated, giving good returns before the properties were taken over by the new concern. —Extensive development is being planned by the Alma-Empire Con. Mining Co., which recently took under bond the Empire and Alma groups of mines, on Groom creek. The deal followed an examination of the Empire mine after the shaft was unwatered. The shaft, now about 400-ft. deep, will be sunk to the 600-ft. level, and the stamp-mill overhauled and some new machinery added. A pump has been ordered for the Alma shaft, which will be unwatered as soon as the pump is installed, and sunk several hundred feet deeper. The Alma and Empire groups consist of 14 claims, covering a series of gold-bearing veins that can be traced for some distance.

CALIFORNIA.

The big vertical shaft of the Kennedy, near Jackson, will be sunk from the 3,000 to the 3,100-ft. level. The 100 stamps in the new mill are running steadily, crushing about 500 tons per day. Webb Smith is the superintendent.

MADERA COUNTY.

The California-Nevada Copper Co. of Daulton within the last 40 days has shipped to the Old Dominion Copper Co. of Globe 640 tons of copper ore, carrying a high percentage of both iron and sulphur. This ore makes a valuable flux for the Old Dominion and the high sulphur is useful in matting and converting. W. C. Braw and J. H. Baker are the manager and superintendent for the company.

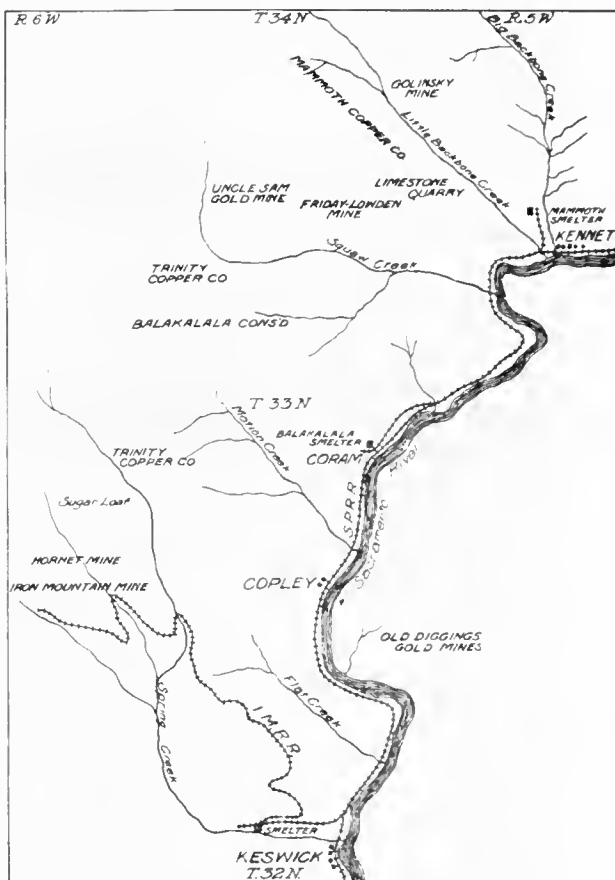

NEVADA COUNTY.

Five more stamps will be added to the 5-stamp equipment at the Republic mine. William McLean and Ed. Foss have been working the property for three years and have run three tunnels opening up a promising vein. McLean &

Co. have recently bonded the property to Eastern men, represented by F. E. Ware, who will work it on a larger scale. —The Bear River Con. Tunnel Co. has driven 200 ft. and the vein is improving. —George F. Taylor has been appointed manager of the Brandy City mines, to succeed Jason R. Leek. The company is preparing to work the old hydraulic mines on a large scale. A rich pocket has been struck in the Rainbow mine on Kanaka creek, a mile below Alleghany and not far from the Tightner. The Rainbow is owned by H. H. Noble, James Clinton, and others, and a 10-stamp mill is on the property. Murdock Morrison is in charge.

PLACER COUNTY.

Fourteen men are working in the Mameluke mine on Georgia hill. —Ernest Garrison is doing assessment work on his quartz claim below Yankee Jims. —It is reported that E. T. Roode has sold his mine at Todds Valley to New York people for \$75,000. —Tom Brown has cut the Paragon gravel in his tunnel. —A. G. Reed is running a tunnel

Map of the Copper Region in Shasta County, California.

toward gravel in the Dardenelles. —The 230-ft. tunnel in the Big Giant mine, near Clipper Gap, is being retimbered, and will be extended 250 ft. to cut the vein. Fred Dependener is in charge, and the property is owned by L. Tyler, D. Jones, and H. O. Yarrow. —W. E. Howell's tunnel, which is being run for the Louise vein near Yankee Jims, is in 250 ft., in a dolomitic country. —A tunnel is being run on the Annie Laurie, by Vere & Young.

PLUMAS COUNTY.

Cement gravel has been struck in the 450-ft. tunnel of the Piston Mining Co., operating on Spanish peak. P. C. Daniels is president of the company, and G. W. Cartwright secretary. —The lower tunnel of the Indian Valley mine is in 420 ft., but the ore-shoot will not be struck until the 300-ft. point is reached. Ore will be stoped from the upper tunnel, until the lower one is completed. Thirty men are employed, and machinery for a 20-stamp mill has been ordered, with a cyanide annex. —The Newton M. & D. Co. is operating its placer ground by using scrapers to bring the dirt to a central point, as the deposit is shallow. C. G. Norris is in charge. The North California M. Co. may work a large part of its ground in the same way.

SHASTA COUNTY.

L. D. Ball is equipping the Yellow Butte mine, east of Weed, with a gasoline hoist. The shaft is down 90 ft.—A large amount of machinery is being hauled from Redding to the Black Tom company's camp at the old Niagara mine at French Gulch. F. J. Seibel is superintendent.—The ore in the tunnel at the Vulcan mine is improving with development.—A new 30-ton locomotive has been purchased for the Mammoth Copper Co.'s Quartz Hill line.

SIERRA COUNTY.

Three groups of claims on Sierra Buttes Mtn. have been sold to Ed. S. Shanklin of Ely. The properties include the Buttes Saddle group of 12 claims, the Roman group of seven, and the two Sacred Mount claims, adjoining the Sierra Buttes quartz mine. Some development work has been done, chiefly by tunnels, and there is a 10-stamp mill on the Buttes Saddle mine that is connected with the workings by a 6,000-ft. aerial tramway. There is also crushing machinery at each of the other mines, the three giving a probable capacity of 150 tons per day.

SISKIYOU COUNTY.

(Special Correspondence).—An Eastern company is preparing to operate the Mountain Laurel mine on a large scale.—The California Con. G. M. Co. is preparing to work the Ball and King Solomon properties. The mines will be operated by electricity. The company recently purchased the four-mile Salmon River ditch.—On the Overton, five tunnels have opened up some promising orebodies. The quartz lies in slate and porphyry.—Ore is being taken from several points on the Advance. The south tunnel is being rapidly driven to tap the main orebody.—At the Homestake developments are progressing rapidly, and all the tunnels are in ore. A raise is being driven from No. 3 to connect with No. 2 and a vein was recently struck in No. 4 tunnel.

Sawyers Bar, Sept. 18.

TRINITY COUNTY.

William Montgomery and associates have bonded the Mountain Boomer mine at Denny, on New river, and commenced work in the lower tunnel, which was stopped two years ago. This mine has yielded ore for 35 years, being especially productive when owned by Ladd & Clemens.—It is reported that Humboldt people are developing a promising quartz property in the upper South Fork country.—The Brackett mine, in the Lower Springs district, owned by E. W. Brackett, has been sold to Eastern capitalists by H. O. Cummins, to whom it was under bond.—At the old Bell mine at Sunny Hill, operations are confined to cyaniding the tailing from a 5-stamp mill. As soon as enough water is available for power, work will start in the mine. This mine is owned by the Marina Mariscano Co., is well developed, has produced gold, and is superintended by L. F. Barlow.

M. P. Rose has built a new *arrastre* at his property on Coffee creek.—The Nash placer mine on Coffee creek is closed, after a successful season's run, but driving is being done in the upper workings one mile above the mouth of Union creek. This company has operated three giants all summer, and employed 15 men. Louis Maitland is in charge.—Several tons of ore have been shipped to the Kennett smelter from the Poeth mine. A compressor and Hugg water-wheel will be installed, the water being brought through a high ditch from Boulder creek.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Waldorf M. & M. Co. will operate the Tobin mine under the leasing system. Six leases have been granted and others are being considered.—It is announced that the Red Oak property is about to pass into the hands of a Chicago corporation for \$150,000. It is expected that active operations will commence before Oct. 1.—The Sidney tunnel sent 10 tons of ore to the smelter a few days ago, that went \$50 per ton. The ore contains silver, lead, and zinc; 15 tons are awaiting shipment.—It is reported that the new mill at the Linn Consolidated will be ready for service by the end of October.—

Development is under way at the Capital group. The east and west drifts are in 300 ft. on the Etna vein. A mill, with a daily capacity of 100 tons, is being constructed.—The Atlantic district is attracting attention.—At the Coffey a 3-ft. vein of \$50 ore has been encountered in the adit. A large body of mineralized quartz is also exposed.—A small vein of ore running high in gold and silver has been struck in the Scotia tunnel.—Two veins have been discovered on the Atlantic group, carrying gold and silver. A cross-cut will be driven to open the ground at depth. A. A. Ireland is manager.—A 16-in. vein of lead ore running \$80 per ton has been struck in the upper workings of the Paymaster. The ore carries some silver.—The Riley lease on the Sunburst is producing some silver ore of fair grade.—The Collins group has been bonded by the Premier M. & L. Co. The adit on Collins No. 1 is in 350 ft. and will be extended 300 or 400 ft. by the bonders. The bond is for \$7,000 and runs two years.—The Calla tunnel on the Ruby Argentine is in approximately 1,000 ft. and is being steadily driven forward. Where the Calla vein was cut a body of lead ore running \$25 per ton is being developed.

Georgetown, Sept. 12.

(Special Correspondence).—The Seven-Thirty Leasing Co. has taken a lease for two years on the Dives-Pelican and Seven-Thirty Mining Co.'s properties, and will put the mill in shape for handling the dump and stope-filling as soon as possible. The mill will be increased to a capacity of 250 tons per day, and a tramway will be built for transporting the material to the mill. C. M. Fueller, of Denver, will have charge of the work.—The Seven-Thirty vein has recently been cut by the Burleigh tunnel, and at the point of intersection it is about five feet wide, showing a pay-streak of from 2 to 4 in., carrying 260 oz. silver per ton, and assaying 30% lead. The Burleigh Leasing Co. is now driving both ways on the vein, in good milling ore.

Silver Plume, Sept. 17.

GUNNISON COUNTY.

There is a good deal of activity at Whitepine camp, on upper Tomichi creek. The Morning Star, which has been operated under a lease by Dodson & Dunlap, will now be worked by J. Reagan, who has bought the lease.—Tutt & Todd are shipping copper-iron sulphide ore from the Morning Glim tunnel, and advancing the Parole tunnel, now in 750 ft.—The Eureka, Nest Egg, and Erie mines are producing milling ore, concentrate from which is sold to the O. & C. smelter at Salida.

The Usona tunnel, in the Copper creek portion of the Gothic country, is developing several groups of claims in the Copper Queen basin. Air will be compressed with water-power. J. A. Goodwin is the manager.—The Coltex Mines Development Co. is operating on the Native Silver, and Gold King lodes.—A contract has been let for 200 ft. of tunneling on the Sylvanite mine, in charge of G. H. Judd.

SUMMIT COUNTY.

(Special Correspondence).—The new mill of the Kimberley Willey Mines Co. is being rushed to completion by the manager, C. L. Buckingham, as fast as material can be secured. It is estimated the mill will have a capacity of 250 tons per day. The plant is arranged as follows: The ore passes over grizzlies to 15 by 24-in. Blake crushers into bins, thence to a set of 12 by 36-in. rolls, the fine passing through other grizzlies direct to the elevator; there are five sets of rolls in all. From the rolls the ore goes to four Columbian screens. The first of the rolls reduce to half-inch, and this product goes to screens while the oversize is returned to other rolls, and this process continues until all the ore passes a 14-mesh screen. From the screens it is conveyed to the bins in the roaster building, to be delivered automatically into the furnace. The iron is roasted at a low heat and is turned into magnetite. After passing through the furnace it is elevated and passed through rotating water-cooler 30 ft. long by 4 ft. diam. This discharges onto another conveying belt, carrying the roasted ore to 10 separate bins in the main building. From here it passes through the 10 Ding magnetic separators. These take out the magnetite. The lead, zinc, and gangue pass onto

another conveying belt to a 16-in. elevator, and are discharged at the top of the mill where water is added and the gangue discharged into two Richards classifiers, making four sizes besides the overflow. Each one of these sizes is put onto two Wilfley tables, where the material is classified, making zinc, lead, and iron products. The iron product from four upper Wilfley tables is discharged onto one lower Wilfley, and the zinc, lead, and middling are handled in the same manner, thus working eight tables in a unit, four above and four below. From the lower tables the concentrate goes direct to the shipping-bins. The wash from the back ends of the Wilfley tables and the overflow from both Richards classifiers, and all of the flue-dust from the roaster is washed directly to the 30-ft. Buckingham filter and settling-tank, where it is dewatered; the thickened pulp is automatically drained off onto Wilfley tables and vanners. There will be 18 Wilfley tables and two vanners. The double roaster is the design of A. R. Wilfley, former owner of the mine and inventor of the table.

Kokomo, Sept. 18.

IDAHO.

IDAHO COUNTY.

(Special Correspondence).—The First Chance mine in Florence Camp, in central Idaho, is to be developed by a number of Grangeville men, who have organized the First Chance G. M. Co., Ltd., with a capital stock of \$1,000,000. The incorporators are J. J. Pulse, William Ingram, G. D. Smith, and W. N. Scales of Grangeville and Daniel Dunn of Florence. The First Chance consists of 10 quartz claims on the highest ground in Florence basin. The claims were located in 1895. The property has been developed by about 1,290 ft. of underground work, most of which is on three claims. The mine is equipped with a three-stamp mill with a capacity of 30 tons every 24 hours. —N. G. Turney and his Spokane associates have taken a \$30,000 bond on the Major group of four claims on American river, near the Buster mine in the Elk City district. The bond runs for one year, and first payment being due March 1, 1908. Development will be begun October 1 and is to continue during the life of the bond. The property is owned by M. Bagley and G. L. L. Baskett of Elk City and George V. Herrington of Spokane. The vein has been opened nearly the entire distance across the property by a series of open-cuts.—The Elk City, Orogrande, and Newsome districts, in central Idaho, are now entering an era of active development under the management of practical mining men. Since F. W. Bradley bonded the Buster mine at Elk City, several weeks ago, things have been moving fast.—I. C. Hallabaugh of Grangeville reports that there is every reason to believe the old Florence district will show activity in the next two years.—The French group of claims, between Newsome and the old Oregon mine, in the Newsome Creek-Elk City district in Idaho, has been sold by Peter Proux to John Leland and Eastern associates for \$35,000. In addition to the purchase price Proux is to receive 100,000 shares of stock in the company which will be formed to further develop the mine. The mine is situated in a district that has for scores of years been operated by Chinese miners, and later by Eastern capitalists. The Buster mine, recently purchased by F. W. Bradley, is within a few miles of the group.

Spokane, Sept. 12

NEVADA.

CHURCHILL COUNTY.

(Special Correspondence).—The Nevada Hills has declared the regular quarterly dividend of 10c. per share, a total of \$75,000. W. H. Webber, the manager, states that a great deal of ore is blocked out, and development is opening up new territory. The company appointed a committee to make arrangements for the construction of a railroad from Fairview to Fallon, a distance of 45 miles.—The Nevada Hills L. Co. is shipping 30 tons of high-grade ore daily to Fallon. Over 1,000 tons of milling ore is on the dumps. The lease expires Sept. 30.—On the 200-ft. level in the Fairview Eagle, the vein has widened to 15 ft. The company has ordered an air-compressor, engine, and other equipment. Water in the lower levels is causing some trouble.—A Goldfield company is arranging to operate a

lease on the Fairview Hailstone.—At the Eagle's Nest lease, some promising ore has been found. The shaft is being sunk with the expectation of reaching the sulphide zone.—Several leases are operating on the smaller properties.—Local business men are interested in a movement to build a trolley line from the town to the leading mines, also to install an electric lighting plant.

Fairview, Sept. 17.

(Special Correspondence).—The Wonder district is in excellent shape, but the future of the town depends mainly upon the Spider-Wasp and Jackpot properties. Several small properties that were regarded as bonanzas some time ago, have been closed, or are being worked on a small scale.—At the Jackpot, the shaft is down 300 ft., with a cross-cut being driven from this level to tap the main vein. A 12-in. vein of ore is being developed in the drift from the 200 level. Raises have been cut through from the 200 to the 100 level, while numerous drifts and cross-cuts are being driven on the three levels.—On the Spider-Wasp a vein of ore is being developed, and operations will soon be commenced on a larger scale. Several leases are in good ore.—At the National Wonder, the shaft is reported to be going down in ore.—At the Blue Jay, ore of fair grade is reported to be in the shaft.—The Ruby Wonder shaft is going down in ore.

Wonder, Sept. 16.

ESMERALDA COUNTY.

The Goldfield Consolidated company has declared a dividend of 10c. per share, payable October 25.—The production of the Goldfield mines for the week ending September 20 was 3,492 tons, valued at about \$400,000. This increase was expected, as the Mohawk and Combination mines are again producing. During the week there was shipped to the smelters 535 tons; to Nevada-Goldfield Reduction Works, 1,314; to Western Ore Purchasing Co., 1,139; treated at Combination mill, 504 tons of ore. The Nevada-Goldfield Reduction Works received consignments of ore as follows: Mohawk, 443 tons; Mohawk Combination, 362; Red Top, 259; Little Florence, 250; Great Western Mining Co., 22 tons. Total for the Goldfield district, 1,314 tons, of an estimated value of \$164,250. The Western Ore Purchasing Co. received ore as follows: Mohawk Jumbo, 855 tons; Jumbo Annex, 22; Hayes and Monnettedump, 60; Florence Leasing & Mining, 162; Little Florence, 40. Total, 1,130 tons, of an estimated value of \$142,375. The Mohawk mine shipped by rail 535 tons of ore that averaged \$100 per ton.—The shaft of the Rogers-Goldfield syndicate is down 370 ft. A cross-cut to the vein will be run from the 400-ft. point. The shaft on the Rosebud lease on the O. K. fraction will also be sunk to the 400-ft. point, and a cross-cut run for the vein. This property is also controlled by the Warner-Stewart people.—The Mohawk Jumbo continues to be one of the heaviest shippers among the leases of the camp. Most of the ore comes from the 400-ft. level.—The vein cut in the raise from the 385-ft. level of the Florence L. & M. Co. continues to improve.—A pump is being installed at the Gold Crown lease on the Silver Pick. Sinking will be resumed in the 200-ft. shaft.—The No. 3 shaft on the Frances Mohawk lease is down 470 ft. and bottomed in ore.—At the Goldfield Jupiter, they are cross-cutting on the 450-ft. level.—A drift is being run on the Little Florence vein at the 400-ft. level of the Combination Fraction. This vein has already been opened for 170 ft. on this level.—The shaft of the Nevadan L. & M. Co. is down 500 ft. and a raise has been started from the 395-ft. level to connect with the winze that is going down from the 196-ft. level.—After being shut down for several months, the Goldfield Bulldog mine will be worked again. The property lies in the Diamondfield area, and a shaft is down 165 ft., equipped with a 40-hp. electric hoist. Matt Graham is the manager.—The shaft at the Five Friends lease on the Laguna is down 350-ft. C. U. Hyland is the manager.

LINCOLN COUNTY.

Extensive repairs have been made at the Nevada-Utah property and No. 1 shaft is ready for active work.—Sinking has again been commenced in the Susan Duster shaft of the Ohio-Kentucky company. A drift has been run on the

vein from the shaft and a winze sunk. E. L. and A. H. Godbe, shareholders in the company, have been visiting the property.—Development work on the Fortuna property in the Bristol district is opening some good ore.

NEW MEXICO.

GRANT COUNTY.

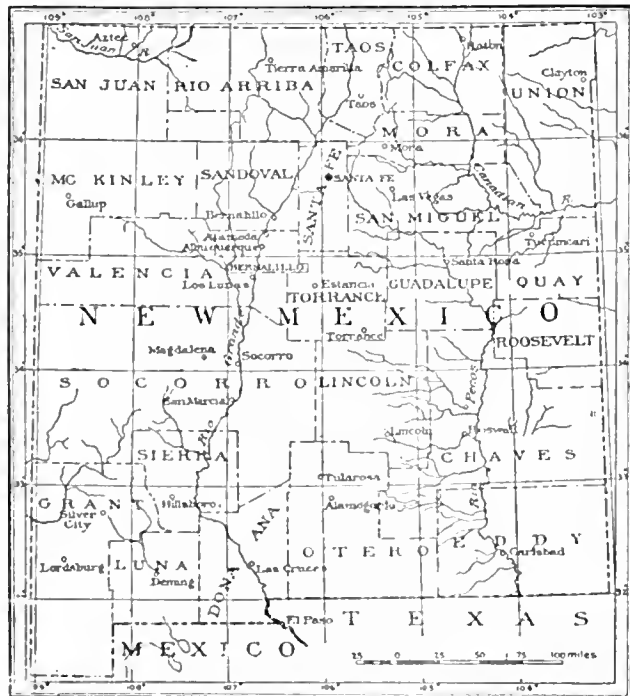

Some good bornite ore was found recently on the sixth level of the Nellie Bly mine, at Lordsburg.—The Bonney Mining Co. will start work again. Some high-grade ore is being shipped from the Misers' Chest mine.—The main shaft of the Granite Gap mine near Stein's Pass, is down 240 ft., and cross-cutting has started.—The King & Queen Copper Co. and the Kuykendall M. & M. Co. have been acquiring many of the copper claims in the vicinity of the Johnny Bull mine. F. A. Jones is the consulting engineer.

LINCOLN COUNTY.

The new cyanide plant of the Eagle Mining Co. will soon be completed. The Vera Cruz mine, managed by Ben Horner, will soon be milling ore. The mill is ready to start, with the exception of the amalgamating plates, which have not arrived.—Work on the Buster Brown copper property is being pushed by W. A. McIvers.

RIO ARriba COUNTY.

Work in the 345-ft. cross-cut tunnel of the Santa Fe has been resumed.—The Red Jacket mill will soon be run-

Map of New Mexico

ning. There has been some delay in the arrival of machinery.—The Emerald mine has been unwatered and sampled by representatives of Eastern capitalists. Levi Reynolds and Murph McKinney are the owners.

SOCORRO COUNTY.

Work on a large scale is to be started by the Rosedale M. & M. Co., owning the Great London and Rothschild properties at Rosedale, 30 miles south of Magdalena. These are old properties, with a shaft 730 ft. deep, and 14 levels.

FERRY COUNTY.

(Special Correspondence.)—The Winnipeg Mining Co. has begun shipping ore to the Granby smelter, at Grand Forks, and will continue to ship 90 tons daily.—The Colville M. & S. Co., on the South Half group, has driven a cross-cut 165 ft., starting from a point in the No. 3 adit 150 ft. from the portal, and tapped the Mountain Boy vein below the bottom of the winze, which goes down from the No. 1 adit. A raise will be made to connect with and drain the winze, when the extraction of ore from the upper workings on the vein will be resumed. The north side tunnel is in 466 ft. in heavily mineralized quartz. A test adit has

been started. The company now owns 59 contiguous claims in the South Half group, covering approximately 1,200 acres of mineral land. A surveyor is on the ground, surveying seven claims of the Mountain Boy group, and the Summit, Eureka, Blue Bird, Orphan, and Alexander claims for U. S. patents. The company will drive an adit from Gold creek, to be 7 by 10 ft. in the clear, to run 2,700 ft., cross 23 claims, and gain a vertical depth of 930 ft. From the North Half group a carload of galena ore has been shipped. A shaft is being sunk on a vein which carries an excess of five per cent iron.—An adit on the Hercules mine, at Park City Camp, is in 330 ft. At 191 ft. in from the portal a cross-cut was started on a stringer, and water is coming in. By driving the main adit 1,200 ft. farther, it would strike into the ground of the Ramore group and gain a vertical depth of 700 ft. Some of the trustees of the Ramore Mining Co. are expected from Montana, and work will be resumed on that property the coming fall. Machinery was talked of, but the Hercules tunnel may be advanced into the Ramore ground instead.—On the Independence group, near the Ramore, there is 1,200 ft. of mineralized ground between granite and porphyry. An adit has been started for its development, and an average sample from along the last 20 ft. assayed \$1 gold and 7 oz. silver per ton. About 100 ft. up the hill from the end of the adit, ore was found at the surface which carried copper and silver. One vein on the group yields rich antimonial silver ore.—The Gilroy group is being surveyed for U. S. patents.—The Amalgamated Republic Mines Co. has paid the second quarter's interest on the mortgage against the Pearl Consolidated Mining Co., which is regarded as evidence that the former will soon get its incorporation straightened out and begin operating the mines.—At Keller camp, copper in blue quartz has been struck in a 200-ft. cross-cut on the Konda mine, on Last Chance hill, at a depth of about 100 ft. The adit will be driven across the vein, when drifts will be started. At the Iconoclast the adit is still in ore.

Republic, Sept. 20.

BRITISH COLUMBIA.

The British Columbia Copper Co. will soon start development work on the Minnie Moore claim, and extension of the Emma and Jumbo claims, at Summit.—The Granby company has taken a bond on the Bullion, Keystone, and Monte groups, on the north side of Phoenix.—The Consolidated company has bonded 10 claims, some of which adjoin the Snowshoe group.—The Lightning Peak G. M. Co., of St. Paul, is doing development work on silver properties in Thunder Hill camp, 20 miles north of Franklin. About 1,000 ft. of work now stands open. The ore is shipped by pack-train to the Arrow lakes and then loaded on boats for the Trail smelter.—The payroll of the St. Eugene mine at Moyie amounts to about \$44,000 per month.—The Victoria mine near Nelson is practically closed down, only six men being employed.—The annual meeting of the Granby company has been called for October 1, at the New York office. During the year ending June 30 the mines produced about 20,000,000 lb. copper, receiving probably better than 22c. per lb. for it. The company has been paying dividends since December, 1903, 22% having been distributed in eight payments since that time.—A good stringer of ore has been found in the Rob Roy claim of the Sally group, on Wallace Mtn., West Fork.—Much of the Snowshoe ore is being shipped to the Trail smelter.—Only two furnaces are running at the British Columbia Copper Co.'s plant, and there is barely coke enough to keep them going.—An incline shaft is being sunk on the Sudbury mine at Deadwood. It is equipped with a 30-hp. electric hoist and is down 100 ft., two shifts being engaged in sinking.—Eight furnaces have been running at the Granby smelter, and about a carload of blister copper is shipped daily. There are 550 men on the company's payroll.—Fifty men are working at the Sullivan mine, near Kimberly, and 100 tons of ore per day are shipped to the Marysville smelter.—A small force of men will be employed during the winter, developing J. O. Coulthard's property on Friday creek. Diamond drilling, which has been carried on at the Nickel Plate since April, has been stopped.

Special Correspondence.

Butte, Montana.

Closing Down of Mines.—Diminution in Copper Production.—Reserves in the East Butte.—The Butte & Bacorn Co.—Butte & London.—Minnie Healey Fire.—The Bullwhacker.

It is doubtful whether the September output of the Butte district will reach 15,000,000 lb. of copper; it may be as low as 10,000,000 or 12,000,000 lb. The ordinary monthly output for several years has been around 30,000,000 lb. The official action of the directors of the subsidiary companies of the Amalgamated in ordering a reduction of 50%, or more, of the normal output, was anticipated by unofficial action, and when word was given out in New York the production had already been curtailed about 60% and the working force of miners had been reduced fully 55%. There was no cessation at that, but the reduction at all mines of the Anaconda, Boston & Montana, Parrot, Butte & Boston, Washoe, North Butte, and Coalition companies continued. A number of mines have been closed completely, including the Minnie Healey and Corra of the Coalition Co., the West Colusa and Leonard of the Boston & Montana, the Berkeley of the Butte & Boston, the Little Mina of the Parrot, and the Neversweat, Belmont, Diamond, Buffalo, Gallatin, and J. I. C. of the Anaconda. Ordinarily there are employed about 10,500 men in and around the mines of Butte. Probably 4,500 have been laid off, and more will follow. The impression here is that the curtailment will continue until there is a practical suspension of mining operations, unless in the meantime there is an improvement in the copper market. Mine managers say that under the present high prices of supplies and labor the companies can make more money by leaving the copper in the ground than they can by mining and selling it under 18c. per pound.

The East Butte Copper Mining Co. has 597,404 tons of ore actually blocked out above the 400-ft. level, according to a report made by William Clancy. On September 17 he placed a net value of \$2,987,020 on the ore in reserve. Mr. Clancy says that cross-cutting has been done to a limited degree below the 400, and a number of veins have been cut, showing relatively the same value as above, but no driving has been done below the 400, so that it cannot be said that ore is actually blocked out there, although cross-cuts have been run. For this reason no ore is estimated below the 400 in his report. None of the drifts on the 400 have been driven to the end lines. When this is done, or when the veins mentioned have been fully developed, there will be 8,352,650 cu. ft., or 835,265 tons additional blocked out. The ore above the 400 carries an average value of 3.11% copper, 2.2 oz. silver, and 30c. gold per ton. Making allowance for the veins not yet fully opened by drifts on the 400, Mr. Clancy estimates the value of the orebodies known above the 400 level at \$7,163,345. The mine is opened to a depth of 900 ft., and cross-cuts are being run on the 800 and 900-ft. levels. In line with the policy of all local mining companies, the East Butte has curtailed its operations, and shaft-sinking has been stopped for the present; the lessees are still working, though their output has been restricted, as the smelters will accept only a limited amount of ore from them. The company itself is still cross-cutting on the 800 and 900-ft. levels, the object being to open as much ore as possible in anticipation of building a large concentrator.

H. L. W. Hyde, of Pittsburg, one of the stockholders of the Butte & Bacorn Co., was in Butte last week and spent some time in examining the property. He

expressed himself as confident that the Butte & Bacorn would become a producer in a few months. He believes that commercial ore will be found at the present depth of 1,000 ft. All development and exploration work at present is confined to the Calumet claim. The drift from the north cross-cut now extends for a distance of 300 ft. eastward and is in sulphides, though commercial ore has not yet been reached. However, the streak is widening gradually and it is confidently believed that an orebody is not far distant. The water is increasing, a fact that is also encouraging. The drift from the south cross-cut is also progressing rapidly, and is in about 100 ft., disclosing good mineralization.

The local representative of Patrick Clark, principal stockholder of the Bullwhacker Mining Co., makes a denial of the report that the Pittsburg & Montana Co. has purchased a controlling interest in the Bullwhacker. Clark owns 800,000 out of 1,000,000 shares of Bullwhacker. The Bullwhacker adjoins the Pittsburg & Montana ground on the east and some of the veins in the latter extend through, or at least into, the Bullwhacker.

The Berlin cross-cut, which is being driven north from the 1,600-ft. level of the Jessie, has penetrated the ground of the Berlin claim but has not yet reached the main vein. The ground has been bad and progress has been slow. In line with the policy of all the big copper producers, the output of the North Butte has been considerably reduced, but the statements published that the mine was running low on first-class ore are erroneous. "The physical condition of the North Butte has never been so good in the history of the company," says Manager Carson. "The mines show up excellently and are constantly getting better." Others familiar with the North Butte mines say the property is 50% better now than it was when the stock was selling at \$115.

The Minnie Healey mine of the Butte Coalition Co. is again producing within about 100 tons per day of its normal output. The work at present is confined to the 1,100-ft. level and to opening the 1,300 and 1,400 levels. No mining is being done above the 1,100. When trouble was caused by the fire and gas the company had been doing some mining on the 1,000-ft. level, and that is the only work that has been hindered. No work was being done above the 1,000. Conditions in the Minnie Healey, West Colusa, and Leonard are gradually improving. By the opening of the orebodies on the 1,300 and 1,400 levels under the stopes of the 1,100, the reserves of the Minnie Healey will be tremendously increased, and the capacity to produce will be limited only by the hoisting facilities. All of the other mines of the Coalition are producing the usual quantity of ore. Owing to the reduction of output caused by the trouble in the Minnie Healey, the Coalition has not yet followed the example of other companies for a general reduction in output. The Corra mine is producing about 250 tons of ore per day. The 1,700-ft. level of that mine is being opened. The shaft has been sunk to a depth of 2,270 ft., and the shaft-work is just being completed. A station will be cut at the 2,200. A connection will be made from that point with the workings of the Diamond mine and the veins will be developed at that depth.

The damage done to the plant of the Butte & London Co. by one of the recent heavy wind-storms has been repaired. All of the big stacks had been blown down and sinking was for a while interfered with. The shaft was deepened to the extent of 74 ft. in August, and is now about 1,100 ft. deep. The company offered the shaft-men a bonus for every foot attained in excess of 70 ft. It is expected that by the first of October the shaft will be 1,200 ft. deep. It is the intention of the company

to sink 300 ft. more in addition to that before any cross-cutting and exploration is done.

Denver, Colorado.

Glenwood Springs Power-Plant.—Non-Union Men at Smuggler-Union.—Corrupt Mining Periodicals.—Lost Bullion-Spanish Mines.

The mining people of Leadville are congratulating each other on the rate of progress made by the Central Colorado Power Co. in constructing its power-plant near Glenwood Springs. A temporary plant is in operation near Shoshone falls, which furnishes the power needed for the main work. The construction of the dam at the falls and the driving of the tunnel that is to serve as the flume are both progressing rapidly. At certain times of the year the plant will use nearly all the water in the river. Some trouble was anticipated from the farmers who have taken up water-rights beyond Glenwood Springs, but this has subsided on pointing out that the power-plant does not decrease the flow, as all the water goes back into its original channel after having yielded up its energy. In fact the plant will be an actual benefit to the irrigators, for it will tend to steady the flow of the stream to some extent. Curtis & Hine is the firm that is conducting the work, while it is understood that Thomas A. Walsh, ex-Governor Herrick of Ohio, and other men are behind the project. Unlike many other plants on mountain streams, this will furnish a constant quantity of power throughout the year. The advantage of this in stimulating prospecting and development work in the outlying districts of Leadville will be great. It will be some time before the entire plant is in operation, however. In Summit county the same corporation is planning to invade the field now monopolized by another power company. The Central Colorado company is supposed to have the backing of the General Electric Co., while the rival company is in touch with the Westinghouse interests. In the lively competition that is likely to result, the consumer ought to be able to reap his full share of advantage.

Robeson & Carter have surrendered the two-year lease on part of the Smuggler-Union property, on its expiration, and the company will immediately begin to work it on company account. It was recently announced by the management that no union men would be employed. When, a short time ago, the Liberty Bell announced that the open-shop system would thereafter be employed, a large number of non-union men joined the union. It remains to be seen whether the Smuggler-Union will be able to carry out its intentions.

Colorado is especially unfortunate in the class of mining periodicals which are published within her borders. Most of these publish in their editorial columns a lot of benevolent rot concerning their solicitude in protecting the unwary investor from being imposed on by fraudulent schemes, and then devote the rest of their columns and advertising matter to boosting lost hopes and puffing barefaced frauds. A favorite and frequent dodge of these gentry is to pervert an utterance of some reputable person or body, so as to make it appear as an approval and official sanction of their schemes. In a recent issue of one of these a company whose chief asset seems to be its press agent, publishes a map from a recent bulletin of the U. S. Geological Survey, on which their locality is shown (because it happens to be a railroad station), quotes beneath it the few lines in the bulletin in

which the geological structure about their prospect hole is described, and then brazenly heads the advertisement in large letters, "Mines receive the stamp of Government approval." Such unadulterated faking can only amuse men with a knowledge of mining; but just where the editorial solicitude for the unwary investor comes in, is not clear. A little further along in the same paper is published as an advertisement a letter from a stockholder, who, on the evidence of his own statements, knows less about mining than he does about making shirtwaists, in which he gives unqualified endorsement of the claims of the promoters concerning the value of the property. Such journalism almost reconciles one to the idea of Government ownership. The Lost Bullion Mines Co., by the way, still continues to sell stock at its Denver offices to those foolish enough to want it, entirely unabashed by the sending of its promoters to jail. With the cutting off of its mail facilities, its power to defraud was also largely curtailed.

Mexico City.

The Ebano Oilfields.—Operations in the San Pedro District.—Old Dumps at Pinos.—Fall in Copper.—Wide Anxiety.—Uncertainty of the Outlook.

Edward L. Doheney, after years of intelligent work in

Mexico.

the Ebano oilfields in the State of San Luis Potosi, has shown the extent of the deposits, and the successful use of this oil in the engines of the Mexican Central Railroad has proved, notwithstanding its asphaltum base, that it has a commercial value. He has therefore reorganized the Mexican Petroleum Co., of which he is president, increased the capital to \$50,000,000, and in addition to the enormous fields around Ebano, has acquired immense tracts in the neighboring States of Tamaulipas and Vera Cruz, making a total area of several million acres. Additional wells will be driven, and after thoroughly canvassing the Mexican markets it is the intention of the company to enter the Central and South American markets in open competition with other dealers. Of the other mining interests in the State of San Luis Potosi, the Barreno Mining Co., in the San Pedro district, after a thorough test of the ore, has completed the erection of its cyanide mill and is now treating from 70 to 80 tons per day of material running about 2 oz. silver and 8 dwt. gold, the resultant precipitate being from 400 to 500 fine silver and 80 to 90 gold, the higher grade and leady iron ores being shipped to the smelter. At the Santa Rita y Anexas mine, at Pinos, a 50-ton cyanide plant is being erected by Gayan and Vacher of Mexico City. The first cyaniding in San Luis Potosi was started about five years ago in a small way on the old dumps left from the patio

work on the ores of the San Pedro district. The treatment of these old *jales* gradually grew until now there are several plants working on them alone, besides the Barreno Co.'s new mill. At Matehuala, in San Luis Potosi, the National Metallurgical Co., under Samuel Janies, continues with the same success that has marked it from the first and is smelting about 500 tons daily.

The continued rapid fall in copper, which has already caused mining men throughout Mexico to concede that it may go well below 14c. per lb. before recovering, has even now led to the closing down of several small properties, put a stop to a number of important denouncements that were contemplated, and given rise to anxiety concerning the effect upon Cananea and Sonora generally. Will the Greene-Cananea Co. continue its splendid, but rather gigantic alterations? The fourth of the eight furnaces has been replaced by the larger size and is in blast, but will the others be replaced as contemplated, that the tonnage may be raised to the 100,000 tons per month, or double the present capacity? Will the price of copper cause a curtailment of the work, or will it force the company to a more rapid completion of the alterations and improvements in order to produce copper at a profit under the present market conditions? These are the questions that are being asked and the answers will be awaited with more than common interest. But it is not only the action of the Greene-Cananea, though with its 60 square miles of ground it stands well in the lead, that will be closely watched, for there are some dozen or more mines that are important factors, possibly more by reason of their ownership than of their production. First of these stand the Phelps-Dodge Indiana-Sonora and Sierra de Cobre mines, which are sending several hundred tons daily to the Douglas smelter; then the Democrata, with its own smelter at Cananea; the Arizpe Mining Co., which has just completed its 18-mile wagon-road from Cananea to Arizpe, and was contemplating a railroad and smelter for the proper development of its 10 square miles of territory, and whose Alacran and Paloseco mines are already splendid producers; the 2,500 acres known as the Cananea Nueva, north of the Greene-Cananea, just acquired by the Lewisohns from Lindsay & Talbot; the Cananea Western of C. M. Schwab; the Cananea & Bisbee of Thompson and Guggenheim; the South Cananea of the Mitchells; the Calumet & Sonora of strong Michigan capital; and the Bonanza de Cobre of Cole, Lindsay, & Talbot. How many sails will they reef in order to weather the storm? And may not some go under, or change captains before it is passed? The position is certainly claiming the attention of all, even of the small operator who is also being hurt. The end—*Quien Sabe?*

There is a good deal of activity at Guanajuato. The Mineral Development Co. has sunk the Nueva Luz shaft to 850 ft. It is intended to sink to 2,300 ft. and cross-cut at that depth, so as to cut the Valenciana vein. This is an enterprise of the greatest importance to the future of the surrounding region. The old workings of the San Cayetano are being sampled with a view to ascertaining how much milling ore is available. The shaft of the Humboldt mine is being sunk at the rate of 5 metres per week. The new addition of 80 stamps at the Bustos mill has been completed and 160 stamps are now in continuous operation, under the management of the Guanajuato Reduction & Mines Co. The San Tomas mine on the northwestern slope of Gigante is being re-opened for quicksilver ore. The Santa Elena Co. in the La Luz district has resumed operations.

The 800-ft. tunnel that has been driven on the Matulera claim of the Green Gold-Silver Co. at Ocampo, will be lengthened to 1,200 ft., which will give nearly 400 ft. additional depth on the ore.

Cripple Creek, Colorado.

Discoveries in the Isabella.—Leases on the El Paso.—Sinking the Delmonico Shaft.—Strike in the Mattie L.—Successful Leasing.—More Cyanide Plants.—Jerry Johnson Report.

The new orebodies found in the Isabella mine on Bull hill several weeks ago and the recent report of their increased size with development have caused a brisk trading in the shares. On the 10th inst. 6,500 shares were sold at 21½ cents and the next day 3,500 shares.—The larger of the mills on Ironclad hill operated by the Phoenix Co. has produced a retort of 256 oz. as the result of a 10 days run. The retort was consigned to the U. S. Mint at Denver. Low-grade oxidized ore averaging \$3 per ton was treated.—The workings of the El Paso mine on Beacon hill above 600 ft., the present water level, are to be leased. Work on company account is to cease until the drainage adit reaches the point where it will unwater the lower levels of the El Paso, which it is reported will then be operated by the company itself. The leases to be granted call for all shipments to be made to the Golden Cycle mill at Colorado City when that plant resumes operation.

Sinking the main shaft of the Delmonico mine on Bull hill is progressing rapidly on company account. The shaft is now down 850 ft. and work will be continued until a depth of 1,000 ft. is attained. The company is also making intermittent shipments of ore from the 700-ft. level. Treweek & Co., leasing between the second and third levels of the main workings, recently shipped a carload of ore valued at \$30 per ton. Their shipments average four carloads per month.—Peterson & Jones, who made the rich strike on the Mattie L. claim at the surface, are sinking on the orebody and have a shaft down 20 ft. This claim adjoins the Anchoria-Leland to the east on Gold hill. The vein has diminished in size from 4 to 2 ft. since first being struck but is still of fair grade; a carload is nearly ready for shipment.—A car of ore has been sent out by the Gold Dollar Co. from the Husted shaft of the Mabel M. on Beacon hill which settled for \$77 per ton at the Standard plant of the U. S. R. & R. Company.

The Beacon Hill Con. Mines Co. have deeded a right of way through the North Slope claim on Beacon hill to the Cripple Creek Drainage & Tunnel Co. The adit being driven from Gatch Park will pass through this territory. The grantee reserves all mineral rights.—Regular shipments are being made from the Black Diamond claim on Galena hill to the cyanide mill of the Wishbone Co. on Spring creek. This company recently obtained a lease on the Black Diamond and is breaking ore 4 ft. wide at a depth of 200 ft., which is shipped without sorting to the mill and averages \$8 per ton.—It is stated that the W. P. H. mill on Ironclad hill is to be in operation by the end of this month. This mill is being built by Groch & Woodward for the W. P. H. Leasing Co., which has a large tonnage of low-grade oxidized ore broken in the stopes of the W. P. H. property. Ore from the Jerry Johnson mine on the same hill under lease to Henry Dahl will also be treated in this mill.—The Trilby Mines Co. has practically decided upon the erection of a 100-ton cyanide plant for its property on Bull hill.

The Humphreys-Thompson Leasing Co. has shipped four cars of ore from its lease on the Little Clara of the Work Co.'s property on Gold hill; this should run about \$80 per ton. Two cars have also been sent out from the Callie claim on Gold hill, operated by the above leasing company; returns of 2 to 3 oz. per ton are expected.—On the 11th inst. the surface plant of the C. O. D. mine on Gold hill at the head of Poverty gulch was destroyed by fire, the origin of which is unknown. An estimate

of the loss is put at \$20,000, with but little insurance. The property is under lease to Cripple Creek parties, but was not being operated at the time, although the 6-drill compressor was running to supply neighboring mines with air.

The annual report of the Jerry Johnson Gold Mining Co. has been received by the shareholders. During the 12 months, 2,221 tons of ore were sold. The gross value was \$91,898, giving an average value of \$41.33 per ton. Freight, treatment, and sampling amounted to \$26,922. The main workings are under lease to Henry Dahl, who did over 5,000 ft. of development on the various levels. The main orebody is between the 300 and 400-ft. levels and varies from 4 to 14 ft. in width. It is an entirely new vein. The W. P. H. Leasing Co. is operating on the west end of the W. P. H. claim of the Jerry Johnson property through a shaft 350 ft. deep. On the 300-ft. level ore assaying from \$5 to \$24 per ton is being broken; this is to be treated by the cyanide mill (to cost \$30,000) in course of construction.—Operations through the main shaft of the Ajax mine on Battle mountain have ceased for a time. The high rates of freight and treatment on the lower grades of ore is given as the cause of the shut-down. A large amount of low-grade ore has been opened up on the various levels of the Ajax. It is stated that operations will be resumed on the completion of the Golden Cycle mill at Colorado City. This shut-down does not affect the lessees, who are working through surface shafts on the property.

Leadville, Colorado.

Increased Production.—Important Mining Deal.—Coal Prices.—Tendency to Use Electricity.—The Grand View.—A Trespass Suit.—New Orebody in the Robinson.

It is estimated that the production of the Leadville district for the month of September will exceed that of August, which was approximately 78,000 tons.

The president, W. W. Degge, and E. R. Johnston, of the Wellington Development Co., have made a deal which secures one of the largest acreages of mineral land controlled by any one company in Lake county. One of the latest acquisitions is a large group of claims in the Horse-shoe district, near the Mosquito range. Among the group of claims are the Last Chance, Dauntless, and Eureka. Development work will be pushed as rapidly as the present installations will permit. It is intended to erect a new plant of machinery before the close of the present year. These claims have been developed by inclines and the dumps are valuable principally for lead and silver. A train has been constructed to transport the ore to the Colorado Southern railroad. But of more importance than the above group, is the acquisition of the large mineral territory owned by T. S. Wood, this exceeds 2,500 acres. Some of the Wood properties have been substantially developed, while much of it has been prospected thoroughly enough to indicate its probable value. These two new additions to their property makes this company one of the most prominent of the district.

The announcement by the coal trust (Victor Fuel Co., Rocky Mountain Fuel Co., and the Colorado Fuel & Iron Co.) of an advance in price on all coals shipped to Leadville, has created considerable comment. The new rate, which has just gone into effect, is the second advance made within twelve months, and raises the price of coal exactly \$1 above the price paid by the consumer a year ago. There is but one solution of the problem as far as the power consumers are concerned, and that will be a complete change from the use of coal to electricity. As a matter of fact, the introduction of electric power by the Leadville Light & Power Co. at 12 cents per kw. has

already created a favorable impression, and the advantages of electrical installations over the steam-plant, with an uncertain coal supply, is being thoroughly appreciated. In fact, a number of important installations are using electric power entirely. The whole district is looking forward to the completion of the hydro-electric plant that is to furnish power throughout the State, after which coal will only be used at mines of less importance.

The development work at the East Lake Co.'s property, under the direction of J. E. Miller, is making rapid headway. The adit is now in more than 1,000 ft. Indiana capitalists have financed a company to develop the Grand View and adjacent claims in Empire gulch. The main shaft will be deepened and a level will be driven on the contact. The ore now available is suitable for a concentrating plant, and the new company expects to erect such a mill.

Salt Lake, Utah.

Dividends.—Ore Shipments From Park City.—Annual Report of the Consol. Mercur Co.—Majestic Shuts Down.—Scarcity of Fuel.—Shipments From Tintic.—New Mills Nearly Ready.—The Western Pacific.

The Silver King Coalition has posted its usual quarterly dividend of \$187,500, which will be paid in Octo-

A Part of Colorado.

ber. The directors of the Columbus Consolidated are to meet within a few days to post the quarterly dividend of that company for payment in October also. The amount will be 20 cents per share on the issued stock—about 260,000 shares. Six mining companies posted dividends and paid them during September, as follows: Uncle Sam, \$15,000; Grand Central, \$12,500; Colorado, \$120,000; May Day, \$12,000; Lower Mammoth, \$11,250; Daly West, \$108,000.—The ore shipments from Park City last week amounted to 1,803 tons, the contributing mines and amounts being: Silver King, 624; Daly Judge, 447; Daly West, 602; Little Bell, 106; other mines, 79 tons. Preparations are well advanced looking toward the construction of a mill at Park City for the treatment of the zinc ores of that camp.

The annual report of the Consolidated Mercur Co. has been issued and shows cash on hand amounting to

\$67,154. The net profits amounted to \$14,553. Two dividends were paid, of \$25,000 each; but the year began with a balance in the treasury of \$127,195. A total of 245,169 tons of ore was mined and milled; the extraction averaged \$2.62 per ton and the loss in the tailing averaged 98 cents. Including the dividends of the DeLamar Golden Gate mine, which is now a portion of the Consolidated Mercur, the latter has paid \$3,385,312 in dividends.

Articles of incorporation of the Lion Hill Consolidated Mining Co. will be filed within a week. This has taken form as the result of the consolidation of the Chloride Point, Northern Light, and Columbia mines in the Camp Floyd, or Mercur, district.

A criminal suit has been recently filed by District Attorney Hogan, against John Ring and Helmar Ostrum, lessees on the St. Louis property, charging them with the theft of \$25,000 worth of rich ore from the Fanny Rawlings. The defendants had extended their operations from the end-lines of the St. Louis adit into the Fanny Rawlings ground. T. D. Kyle notified the offenders to cease work, which they did, but they resumed about a week later, and were arrested on the charge of ore-stealing.

The Majestic Copper Co. has ceased operations at its Old Hickory mine in Beaver county. For several months the company has been shipping a very low-grade copper ore from which a satisfactory profit was earned when the metal sold above 20c. per pound. The recent drop in copper, however, makes it impossible to operate the mine without a loss.—Electric power is rapidly taking the place of steam in several Utah mining camps and this change is being wrought much sooner than it otherwise would have done had it not been for the scarcity of fuel last winter. The Utah Consolidated at Bingham has practically all of its equipment electrically driven now and within the next few weeks the new electric haulage system will be ready. The Lower Mammoth, at Tintie, has been the latest company in that camp to make the change. When the Boston Consolidated first planned the Garfield mill it was intended to operate its own steam plant and generate its own electricity; but the management decided that it would be advantageous to buy power from the Telluride Electric Power Co., and an agreement to run for a term of years was entered into. The Telluride company operates several water-driven plants in Utah, Idaho, and Colorado.

The ore shipments from the Tintic district last week amounted to 158 carloads, the contributing mines and respective amounts being: Ajax, 3; Beek Tunnel, 11; Bullion Beek, 2; Colorado, 12; Curisa, 3; Centennial Eureka, 55; Clift, 1; Depue, 4; Eagle & Blue Bell, 12; Eureka Hill, 3; Grand Central, 8; Gemini, 5; May Day, 9; Mammoth, 9; Scranton, 7; Swansea, 1; Silver Peak, 1; Uncle Sam Con., 8; Yankee Con., 2 carloads.—A petition has been filed in the district court to disincorporate the Star Consolidated Mining Co., the property of the organization having been transferred recently to the Black Jack Co.—The management of the Utah Copper Co. has reported that the new Garfield mill has been treating ore during the current month on the basis of 100,000 tons monthly. Less complaint has been heard as to the service rendered by the Rio Grande Western in transporting ore from the mine in Bingham to the mill.—The construction of the Ohio Copper Co.'s mill, at Bingham, is progressing satisfactorily, and the contractors think they will have at least a portion of the plant ready in December. It is being constructed in four units, each to handle 500 tons.—The Boston Consolidated mill at Garfield will soon be completed.

London.

Cornish Tin Mining.—East Pool & Agar United.—Peter Watson is Optimistic.—Grenville United.—Condurrow United.—Carn Brea and Tincroft.—Dolcoath.—Elmore Process Applied.—Mr. Meyerstein's Remarks.—The Mining Market.

During August the stockholders in some of the leading Cornish mines held their general meetings in the County. In each case expressions of satisfaction with the present and hopefulness for the future were the order of the day. At the quarterly meeting of East Pool & Agar United the accounts showed in regard to East Pool a profit on £6,503. The working expenses included dues ($\frac{1}{4}$ s on all minerals) to Mr. A. F. Basset, £1,159. Wheal Agar section showed a loss of £352, consequent upon the charging of the erection of crushing plant to revenue account. The tinstuff sent to the stamps for the quarter amounted to 13,668 tons. The average produce was 23.7 lb. The sales were 144 tons 12 cwt. of black tin, averaging £118 2s. 10d.; arsenic realized £1,733, and wolfram £2,055. A dividend of 17s. 6d. on 6,400 shares was agreed to, leaving the total reserve at £7,504. The dividend is the largest since 1888, and brings up the total from July 1906 to £3 1s. 6d. per share. Incidentally, it was stated that wages were 25% higher than 18 months ago. The manager, Capt. J. Tamblyn, reported that during the last month they had increased the output from the south lode at the 70 and 90-fm. levels, and that 600 tons of stuff had been sent to the stamps, giving an assay of 28 lb. per ton. The future prospects of the mine would depend greatly upon the value of the new north lode. East, west, and at the 280 east of cross-cut they had driven 35 fm. through a lode 10 ft. wide, and the average would be 45 lb. per ton of stuff. At the 290 they had driven 27 fm. through a lode averaging 12 ft. wide and of an assay-value of 50 lb. of tin per ton. In the 290-fm. winze in the last 3 ft. of sinking the value had improved to 70 lb. and they were expecting to reach that shoot of tin on the 300-fm. level any day. The reconstructed dressing-plant at Tolvodden was a success and could not be beaten in the County for the treatment of such low-grade ores.

Peter Watson, the 'grand old man' of Cornish mining, presided at the Grenville United Mines held at the 'account house.' From a report issued to the stockholders, it is apparent that the mine has passed through a somewhat difficult period. Its former manager, Mr. Negus, left for an appointment abroad, and the new manager, Frank Williams, found various difficulties before him, which he has faced with energy and success. He is now able to show that there is a generally improved outlook for the mine, which, at the time he took charge, had not a very favorable appearance. During the half-year ending June 30, the development in the bottom of the mine proved the continuation of the principle shoot of tin to the 320 fm. west of Fortescue's shaft where its length and value have been maintained, but east of Fortescue's shaft there was no improvement, though this is expected when certain work now in progress is done. At the 305 east, after two months' stoping, the main portion of the lode was discovered above, and to the south of the level, having an assay-value of over 100 lb. tin per ton. The development of Goold's section has been fairly satisfactory, but the driving of the 130 west has been disappointing. The equipment of Goold's shaft is complete almost to 276 fm., and every effort is being made to sink and equip both this and Fortescue's shafts. The total tonnage for the half-year was 19,543 tons of black tin, producing an average of 31.78 lb. per ton; 498 persons are employed. The profit was £4,843,

out of which the directors have declared a dividend of 1s. 4d. per £1 fully paid share, and 4d. per share 5s. paid, absorbing £4,500. In his speech Mr. Watson reminded the stockholders that since he became chairman, in 1902, Grenville has divided £39,450. The manager (who is the youngest mine manager in Cornwall) foreshadowed several economies in the working of the mine. He has already centralized the dressing appliances, and he hopes to effect further reductions in working costs by rearranging the existing machinery.

The third ordinary general meeting of the shareholders of Condurrow United Mines was held under the same chairmanship. Mr. Watson said the mine was one that he remembered 50 years ago. It was then producing a large quantity of tin and continued successfully for many years. The £20 shares were selling at £120 or £130, and he believed they paid on each £20 share something like £80 or £90 in dividends. The mine was afterward worked under the name of Pendarves United. In 1868 it was producing from 40 to 50 tons of tin per month when tin was at the price of £57 or £58 per ton, half the present price. In the bottom levels they had lodes worth £30 and £40 per fathom; at the 250 they had a lode worth £90 per fm., which would be worth £175 to £180 per fm. at the present price. Regarding these facts as an illustration of the value of the property in the past he considered the present company's future as likely to be most prosperous. Great satisfaction was expressed by the meeting with the progress made in the erection of the machinery. The rate of sinking the main shaft (which is now cleared to 100 fm. from surface) did not prove a matter for so much congratulation. The chairman explained that their case was similar to that of many old shafts in Cornwall. They are carried down to a certain depth, until a bunch of tin is found, and then their course is diverted from the perpendicular, and they go down zig-zag. That was one of the Cornish methods of mining in the past century, but things are very different now. This crooked shaft it was necessary to make straight, so as to save the undue consumption of coal.

Frank Harvey presided at the fourteenth ordinary general meeting of Carn Brea and Tincroft mines, at the offices of the company. The chairman said that the expenditure during the six months had increased considerably, and also the receipts, but not quite in the same proportion. The wages bill was much higher, not owing to more men being employed, but to a higher rate of pay. Coal and materials had also increased, and royalties had advanced from £1,021 to £2,390. On the credit side, the sales of tin were somewhat less, but there was an increase in the total receipts for metals. Copper had realized less, but arsenic and wolfram more. The result was a credit on the six months of £4,518. Adding to this the balance of £5,068 brought forward from the last balance sheet, the total to credit is £9,587. From this the directors recommended a dividend of 2s. per share on the 38,607 priority shares, absorbing £3,860, leaving £5,726 to be carried forward. Since the limited company was formed in 1900, the net profits have been £34,514, and the losses £21,753. The cost for labor has averaged 17s. 6d. per ton, and for materials 28s. 11d. per ton; 953 persons are employed at these mines. The manager, Capt. Penhalls, described the prospects of the mine as excellent. He particularly mentioned the developments down the Right shaft, which revealed one of the largest and richest lodes seen for years past. He had been in charge three and a half years, but the mine never looked so well as now. The chairman announced that when the ore reserves justified the action, the directors might expend some thousands of pounds on the installation of a modern plant. There is an urgent need

for a rearrangement of the dressing appliances at Carn Brea. It appears that at present the company is making a loss on every pound of tin sold, the profits being derived from by-products.

The series of stockholders' meetings was wound up, on the last day of the month, by Dolcoath, Frank Harvey again presiding. The report showed that the falling off in the quality of the ore treated in the past half-year (37.52 lb. against 39.84 lb.) was more than counterbalanced by the rise in the price of black tin, the total amount realized on sales showing an increase of £2,720 as compared with the preceding half-year, and of \$6,286 over the corresponding period. The profit for the half-year was £41,421 which, with the balance brought forward, made an available total of £57,230. The dividend, at the rate of 20% (as compared with one of 15% a year ago), absorbed £33,804. Out of the remainder £15,000 is placed to reserve, leaving £4,747 to be carried forward. The whole of the 340,000 shares of £1 each issued are now fully paid, and there are 10,000 in the treasury for future issue when required. The chairman stated that during the six months the operations underground had been pushed forward with all energy and with satisfactory results. The dressing plant and machinery had been well looked after, and added to. The Elmore vacuum plant had been erected, and was working well. They were hoping for good results from this plant. It might mean a considerable addition to their revenue in future years. The financial position of the company was really very good. A contract had been entered into for the sinking of the Williams shaft 210 fm. deeper, equipping it, and also erecting, possibly, a new stamping and dressing plant. This would absorb about £60,000 of their balance in hand, and still leave them with a good surplus. R. Arthur Thomas, the manager, said that the breakage of a pumping-rod had caused the water to rise in the bottom workings, and, in consequence, they would undoubtedly have a rather serious decrease in the amount of tin ticketed next time. There was, however, no reason for alarm. The question had been asked: Why, having such a large quantity of rich ground in the bottom of Dolcoath, the produce was allowed to decrease, to the extent of two to three pounds of black tin per ton of stuff; and why was not a larger quantity than about 2.26% of the total stuff drawn from the mine obtained from the bottom workings. His reply was that it had been possible to mine only a relatively small quantity of this ore.

E. W. Meyerstein, a prominent figure in the Cornish Consols and other financial groups, is a 'bull' on mining in the Old County. At the dinner which followed the Condurrow and Grenville meetings he is reported to have said, "there are 600 abandoned mines in Cornwall, and they will doubtless, sooner or later, be re-started. It is in Cornwall that we have the brightest outlook for the future, and this County will be the producer of national wealth for this century such as is not thought of today." In the old days the mines divided profits up to the hilt, and did not put aside anything for a rainy day; but now companies are building up substantial reserve funds. Deep mining has lost its horrors. Modern engineers face with equanimity the tasks upon which their forefathers turned their backs, and today they not only say, "Where 'tis, there 'tis," but "we'll get it out."

The last fortnightly tin 'ticketing' amounted to 245½ tons for £24,731, averaging £100 14s. 9d. per ton of black tin, an increase of 15 tons and decrease of £1 2s. per ton compared with the previous fortnightly sale. With the beginning of September the mining stock markets show signs of a possible improvement in the near future. So far, however, it cannot be said there is anything more than a promise of better times.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

PHOSPHATE rock is used altogether in the manufacture of artificial fertilizers and chemicals containing phosphoric acid.

EXPERIMENTS in cyanidation often give results not duplicated in practice because the interference of foul solutions is eliminated when working on a laboratory scale.

AT Pachuca the Patio process is preceded by fine grinding and concentration on Johnston vanners; these extract the sulphides and the gold, and the tailing from them contains the silver that is extracted by amalgamation on the *patio*.

By rubbing metals with salt, before applying mercury, the ancients obtained a reaction similar to that for which copper sulphate is used. The chlorine released from the salt formed a silver chloride easily attacked by the mercury, so as to form an amalgam.

THE eastern townships of the Province of Quebec furnish the greater part, 85%, of the world's production of asbestos. In 1906 Canada exported 59,864 tons of asbestos, valued at \$1,689,257, most of which came to the United States. The output is increasing; and in 1906 there were improvements in plant and machinery in some of the older mines, the opening up of new and promising properties, and a tendency toward a consolidation, under one management and ownership, of a number of mines formerly separately owned.

CERTAIN of the nickel alloys are used in the manufacture of electrical instruments. Nickel is one of the comparatively rare metals, and only recently has it come into wide use. It has been cheapened by the discovery of new sources of supply, and by improvements in the methods of production. It is white in color, malleable and ductile, and closely resembles iron in all its properties, with the one exception of great practical importance that it does not rust on exposure to moist air. It is this property which led to its wide use as a protection for iron and other metals which corrode easily.

THE high cost of tin has greatly concerned the makers of anti-friction metals, who have cast about for a cheaper substitute. Siemens and Halske, of Berlin, have patented a new alloy for this purpose. It is composed of 45 to 50 parts of cadmium, 45 to 50 parts of zinc, and up to 10 parts of antimony. The antimony added should not exceed 10%, as otherwise the metal is too brittle. A suitable proportion of antimony is 5%. If the proportion of cadmium and zinc is varied, the coefficient of friction increases, and the other good properties of the alloy are essentially diminished. The mixture is claimed to be superior to the ordinary white metal.

THE phosphorus obtained by most commercial processes is a crude form of the white or yellowish waxy variety, and contains sand, carbon, clay, and other impurities. These are removed in various ways—by filtering while molten through powdered charcoal or canvas submerged in water, by forcing the molten mass through porous pottery by means of steam, and by redistillation in iron retorts. The best method of purification, however, is to treat the crude phosphorus, when molten, with a mixture of potassium dichromate and sulphuric acid,

or sodium hypobromite, some of the impurities being dissolved, others rising to the surface as scum.

IT is only recently that phosphorus has been extracted from mineral deposits. The mineral from which phosphorus was first obtained was phosphorite or rock phosphate, an impure fluophosphate of calcium, from which soluble phosphate fertilizer is generally made. Apatite, a fluophosphate or chlorophosphate of calcium, has been used in Europe and Canada to a small extent, but wavellite (aluminum phosphate) has not been heretofore used commercially, as far as known, in the manufacture of phosphorus, as the mineral does not generally occur in minable quantity. A deposit of wavellite at Mount Holly Springs, Pa., has recently been mined for this purpose and has been successfully reduced in the company's plant by a secret process.

A GENERAL DEFINITION for a schist is a metamorphic rock that is laminated so as to split with some ease along parallel planes. Schists grade into gneisses and their mineralogy is about the same, but crystalline schists often have finer laminations than gneisses. Schists and gneisses are the most typical and important of the metamorphic rocks, as they are the product of the most extreme alteration of both sedimentary and igneous rocks. They show great variation in texture and mineral content. A schist may be defined as a highly metamorphosed slate, which has become thoroughly crystalline, with the minerals in a parallel arrangement, while a gneiss is composed of the same minerals as granite and only differs from it in the arrangement of the minerals in bands.

BITUMINOUS rock, like any other rock, is obtained by quarrying or excavating, and is a natural mixture of bitumen and the including rock, usually consisting of sandstone or limestone. For paving or roofing it must be crushed, and for successful use the bituminous or asphaltic content must be brought to the proper consistency and quantity with respect to the stone matrix. The mastic extracted from the bituminous rock in the presence of heat and moisture naturally carries a percentage of earthy impurities, as do the malphas and viscous asphalts that occur exuding at the surface of the earth. The extracted and the natural asphalts are used largely for street paving. The natural asphalt imported from Trinidad and Venezuela supplies a large part of the eastern United States for street paving. They are refined and utilized also for roof and other metal paints.

THE name flint is properly applied only to quartz of exceedingly compact texture, dull surface, and perfectly conchoidal splintery fracture. It commonly occurs in the form of more or less irregular nodules in limestones, and in such cases is almost certainly of concretionary origin. Chert is another name applied to flint occurring in this way. Flint or chert nodules occur abundantly at several places in the United States, notably in the Cretaceous limestones of central Texas. So far as known, but little domestic flint has ever been commercially utilized except as road metal, though its quality appears to be equal to that of the imported flint. All the true flint consumed in this country comes from France, Greenland, Norway, and England and is imported cheaply as ballast. Many of the smaller round or oval nodules are used in ball-mills, but much of the material is fired in kilns and then ground for use in the pottery trade. The flints, which are usually gray to nearly black in their natural condition, become perfectly white on burning, and fracture somewhat, so that grinding is facilitated.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Mexican Railroad Tariff.

The Editor:

Sir—The new tariff on ore contemplated by the United Railroads of Mexico, if put into operation, may prove fatal to the whole mining and smelting industry of Mexico. Before committing themselves to such a new departure it would be well for the railroads to investigate if the ore could stand this classification. As a matter of fact, the large shippers are by no means as much on velvet as the public at large assumes. Many mines today would be shut down if it was not for the advances from the smelters. Sierra Mojada, for instance, is shipping large tonnages of low-grade ore almost indispensable for smelting, although the returns are small.

As far as the smelters are concerned, the ore has not been a source of profit for several years. Smelter rates in Mexico are lower on all classes of ore than ever before, this being due not only to keen competition, but mainly to maintain the tonnage in lead, copper, and fluxing ores. The net margins of the smelters are at the limit, particularly with an uncertain coke supply, not to mention the price of it, at \$22 per ton. Many silicious ores now available for smelters, could not be shipped under the new tariff.

Beyond question, the tariff will be farther reaching than anticipated. Judging from the yearly statement of 1906, the increase will be more than 60%. Many large shippers cannot stand the increase and must shut down their mines. It is a case of killing the goose that laid the golden eggs. With a particularly tight financial situation all over Mexico, this new tariff is inopportune, and we may venture the hope that this matter may be deferred until more thoroughly examined.

H. A.

Torreon, Mexico, September 12.

Corrections By the Way.

The Editor:

Sir—I am weary with seeing in your paper many articles which assume that mining is a business, when anybody that knows anything about precious metal mining knows that it is nothing of the kind. Now I am not going to take up your crowded columns with elementary definitions as to what constitutes business, gambling, and mining, but I will boil it down to the statement that there is not today on this planet a single mining camp where a man can take \$10,000 and invest it in a mine without running the danger of losing it all within a few years and with an almost positive certainty that he will at any rate lose a large portion of it. I ought to have stated in the beginning that I confine my remarks to precious metal mines—gold and silver mines—but I don't think I should be far out if I applied to all metal mines.

Some people may ask why is this thus? Very simple, because the rewards are so great that speculative capital is attracted in such amount that the prices of prospects and mining shares are put out of all reason. In 'boom' times mining shares always sell for from five to ten times what they are worth, and even in these depressed times the stocks are selling from two to five times their probable valuation by a conservative engineer, say such engineers as are employed by the Exploration Co. of London, or the Tharsis Co. of Glasgow.

As for mining engineers not visiting anything but

well-known bonanza camps; why, my dear Sir, there isn't a spot on the habitable globe from Nijni Kolimsk in Northeast Siberia to Puntas Arenas where you can't find the tracks of dozens of them and in this desert region there is a procession of automobiles chewing dust all over the State, and there isn't a square mile in Nevada undisturbed by the wandering prospector, who so far this year hasn't hit it to any great extent that we are aware, tho we still live in hopes. The money spent in prospecting and 'scouting' after mines is beyond belief; I can easily count up a million dollars spent for that purpose among a very few firms. One little expedition that perhaps five men have heard of cost \$65,000 and not as good a showing was found as can be turned up within two miles of the Cliff House.

I note too that your deep erudition has gone astray in your last paper where you talk about rhyolite with fossils in it, I think if you called it a tuff strongly resembling rhyolite, you would have been nearer the truth.

Trusting this letter may have a tendency to cast a slight Beam of the Light of Information on the Darkness Cimmerian of Unknowing Enthusiasts, I am,

METALLIFEROUS MURPHY 2ND.

Tonopah, September 12.

[We are pleased to hear from Mr. Metalliferous Murphy 2nd, for we have pleasant memories of the first of that illustrious name. It was at Salmon City, in Idaho, that we met the venerable mineralogist. Being in doubt as to the real nature of a specimen of ore found in a neighboring gulch, we referred the labeling of it to the eminent authority. He said: "It is hoighly magleferous maaterial, bedad; and its chief compoanent paarts is made up ov zinc, lead, oiron, and tin, and the oxhides of copper, and the horns of silver, and iron pirate, and the Devil knows what all; and where did ye foind it, in order that I may go and locate it?" No wonder we are glad to hear from his illustrious successor, more particularly as this communication from Tonopah makes light so many dark places. We had heard of Searchlight, in Nevada, but we did not know that a 30,000 candle-power luminary sojourned at Tonopah. It is greatly to the gain of those who dwell in the desert. Metalliferous Murphy 2nd ought to take the place of a Carnegie library.

Next to saying what a thing is, it is well to say what it is not. Mining is not a business, says he, but a risky gamble. To this we demur. Ask the gentlemen whose ancestors were inside of Jerusalem at the time of the siege and they will tell you that not only is mining a business, it is more than that, it is a 'peeziiness.' And 'peeziiness' may be defined as a highly profitable form of human activity.

As to the high prices of mines, that is true. But if the Great Metalliferous One will throw what does service for a mind into the dim recesses of the past (which is better than a wastepaper basket) he will find that 20 years ago the price of mines was even greater proportionately to the ore reserves measurable at the time of sale. If mining is a risk today, what was it in 1880? At that time mining claims were bought on hand specimens, 'symptoms of indications,' a fine site for a dump, lovely scenery, and what not. We venture to say that nowadays the buyer of a mine gets twice as much for his money as he did 25 years ago. Of course, there are fools that rush where experienced men fear to tread, and in boom days the simpleton is an easy prey to the promoter, but these are exceptions, not rules.

As to the money spent in scouting for mines and mineral discoveries, doubtless in the aggregate a big sum is spent, but we doubt if any form of speculation is

as remunerative in the long run when properly performed. A young bonanza is the most profitable form of mining enterprise, and the exploration companies that get hold of important ore deposits when in a youthful stage of development make lots of money.

Finally, as to the tuff. The rock was made of fragmentary rhyolite and it was rhyolite as to its composition, but differed from ordinary rhyolite in the manner of formation, being due to the interplay of volcanic and sedimentary agencies. A pig is called a pig when it looks like a pig, grunts like a pig, and has other porcine characteristics; the tuff did not only "strongly resemble" rhyolite, it was rhyolite; it was rhyolite-tuff. Our compliments to the Eminent Metalliferous One at Tonopah.—Editor.]

Black Sands and the Mining Bureau.

The Editor:

Sir—I have noticed an editorial in your issue of the 14th inst. which comments unfavorably on Bulletin No. 45, 'Black Sands,' and in which article you take a whack at the Mining Bureau. Without comment at this time on the article, I think it would be wise for you to look over the files of your journal for the past year, and read what you published regarding black sand matters. I cannot recall the exact date of the publication, but I remember that you 'roasted' Dr. Day's methods to a finish. For this reason, I cannot understand your change of heart.

L. E. AUBURY.

San Francisco, September 18.

[Mr. Aubury is mistaken as to the "change of heart," and if he will read the editorial paragraph to which reference is made, he will find that there is nothing in it to warrant the idea he expresses. We consider that Dr. Day's experiments were of no particular value in themselves, and that they did positive harm by being used in a number of prospectuses of a misleading character. They did injury to the reputation of the Survey by connecting it with flamboyant pseudo-scientific propaganda of an undignified character. But the point of our comment, to which Mr. Aubury objects, was that the pamphlet published by the State Mining Bureau was also of no particular value, and while criticizing Mr. Day, it gave no practical information of the kind that might be expected from the Bureau. It was merely a *réchauffé* prepared by a man quite capable, if so instructed, of giving something much more serviceable. Mr. J. A. Edman is experienced in such matters and if serious investigations were to be undertaken by him, the result would be a valuable report on the proper treatment of 'black sands.' Bulletin No. 45 of the Bureau is not such a report; it is a short inconsequential reference to the subject. Yes, we did take "a whack at the Mining Bureau," although we would prefer to say that a criticism was made of a State department that is doing very little at this time to warrant its existence save to take part in the game of grab between two railroad companies that are fighting over the control of land in northern California. We shall refer to this matter shortly; in the meanwhile we would like to see the State Mineralogist so directing the Bureau as to make it useful to the mineral development of California.—Editor.]

"IT SEEMS TO ME," said Lord Kelvin, "that in reality ether is structureless, which means that every portion of ether, however small, has the same electric properties as any portion, however great. There is no difficulty in this conception of something utterly homogeneous and elastic, occupying the whole space from infinity to infinity in every direction."

Report of United States Geological Survey on Effects of the San Francisco Earthquake and Fire on Structural Materials.

Within a few days after the San Francisco earthquake and fire of April 18, 1906, the United States Geological Survey arranged for an investigation of their effects on buildings and materials of construction, and the results of that investigation have just been published by the Survey as Bulletin No. 324.

The report comprises four papers: The first, by G. K. Gilbert, geologist of the Survey and member of the State Commission for the investigation of the earthquake, discusses the shock as a natural phenomenon, especially those features of it which would contribute to an understanding of the three following papers. These treat the subject from the standpoint of the engineer, and describe the effects of the shock and the fire on the various structures and structural materials.

Of the engineers reporting on the subject, Richard L. Humphrey was sent to San Francisco as Secretary of the National Advisory Board on Fuels and Structural Materials, and as a representative of the Geological Survey, in which for the last two years he has had charge of the structural materials laboratories. Mr. Humphrey's investigation began early in May, lasted six weeks, and covered the entire territory affected. Capt. John Stephen Sewell, of the Corps of Engineers, United States Army, was sent to the scene of the disaster by the War Department under order of April 23, to make an investigation similar to that undertaken by Mr. Humphrey. Before going to San Francisco he had made a careful study of the effects of fire on buildings and materials, especially as indicated by the results of the Baltimore fire in 1904. Frank Soule, dean of the College of Civil Engineering of the University of California, who prepared the final paper, had not only had wide experience with his subject, but had the advantage of being thoroughly familiar with conditions in San Francisco prior to the earthquake and of being present during and after its occurrence.

The investigations of the three engineers were conducted independently and their papers were written without collaboration, but the opinions expressed are strikingly accordant in their more important features. The report is profusely illustrated, and a list of other important papers on the same subject which have appeared in technical journals and the proceedings of technical societies during the last year is appended to it.

TRANSVAAL WAGES.—On the last day of the year, ended June 30, 1906, the Transvaal gold mines employed 17,959 whites, 90,882 blacks, and 52,352 Chinese coolies. The white employees, for the most part, are skilled laborers, and the wages earned by them during the year amounted to \$32,207,070, including the salaries of the skilled staffs. This gives an average annual income of approximately \$1,780 per employee. Wages earned by natives, Chinese, and other unskilled workers amounted to \$18,824,635, the Chinese earning \$5,506,550, the natives and other colored employees earning \$13,773,980. The average monthly wage to each worker was respectively \$9.50 and \$12.50. The total wage bill of the gold industry for the year was \$51,031,205, or almost one-half of the value of the gold output. In addition to wages, the unskilled laborers are provided free with housing, medical attendance, and food, the raw material of the last two items amounting to \$3,966,015. The value of the stores consumed on the gold mines during the last official year was \$42,485,610, which, added to the wages earned, amounted to \$93,015,315, or about 84.7% of the value of the total gold output for the same year.

The Combination Mine....I.

Early Development and Geologic Structure.

Written for the MINING AND SCIENTIFIC PRESS
By EDGAR A. COLLINS.

The Combination mine is situated in the Goldfield mining district, Esmeralda county, Nevada, about one-half mile in a northeasterly direction from the main street of the town of Goldfield.

The Combination No. 1 and No. 2 claims were located

The Combination Mine and Mill.

in May, 1903, and the first discovery of mineral was made soon after. In October of the same year, the group (consisting of ten claims, aggregating 175 acres) was bonded by L. L. Patrick, acting for Arthur Winslow and J. D. Hubbard, trustees respectively for the United States & British Columbia Mining Co., and a syndicate of Chicago gentlemen. The amount of the bond was \$75,000, of which \$5,000 was a cash payment, and the balance spread over a period of twelve months. During the life of the bond, the purchasers had the privilege of working the property on a royalty of 25% of the net proceeds, with the understanding that the amounts paid in royalties were to apply on the purchase price of the property. As a matter of fact, the first cash payment of \$5,000 was the only money actually required to finance the property, the balance of the payments being met from royalties, as they became due.

Work was commenced by Winslow and Hubbard in the latter part of October, 1903, at which time the workings consisted mainly of a shallow open-cut and drift or 'tunnel' about 90 ft. long, which exposed 30 ft. of shattered and oxidized quartz and kaolinized material. This was divided into two portions, namely, about 20 ft. in the open-cut, which, according to samples, averaged \$20 per ton, and about 10 ft. near the surface of the drift, which averaged \$150 per ton. The value was almost entirely in gold, which was bright and yellow, so that it made a good showing in the gold pan or horn. In addition to this cut and drift there were several other shallow cuts and pits, two of which exhibited a similar material, which sampled from \$5 to \$10 per ton, while others were location holes in soft decomposed and iron-stained rock.

At this time the town of Goldfield consisted of a few tents, two of which were stores, one was a so-called restaurant providing very inferior food, and three saloons. All were the result of the excitement occasioned by the bonding of the Combination and Jumbo groups of claims, and the spreading of reports of the richness of the ore.

Outside of the individual prospecting which was being prosecuted at this time, the only work in progress was on these two properties, both destined to become important mines.

At the Combination, five or six men were put to work sinking a small shaft on the high-grade ore discovered in the drift, and sacking the ore broken in this manner. At the Jumbo claim on the opposite hill, John Harvey, acting for Patsy Clark of Spokane, took a bond on the property immediately after Patrick bonded the Combination, and commenced a small shaft on the hanging wall of the lode. After reaching a depth of 50 ft., he cross-cut the lode and drove a few feet in both directions. Finding the results of his sampling poor, Harvey stopped work, relinquished his bond, and by so doing just missed by a few feet one of the bonanza ore-shoots of the Goldfield district. Shipments of ore from the Combination commenced during November, 1903, and continued without interruption until the commencement of milling operations in May, 1905. The average gross value of the ore shipped during this period was \$104 per ton, and it is an interesting fact that the first car of ore shipped from the mine, which averaged \$160 per ton, was the lowest in grade that was ever shipped. At first the ore was hauled by teams to Candelaria, a distance of 65 miles by wagon-road, at a cost of \$12.50 per ton; but with the advent of the railroad into Tonopah, the long haul was discontinued, and all ore was taken to Tonopah, and there loaded on the cars for shipment to the Selby smelter at Vallejo Junction, California. By shipping from Tonopah on the

Main Shaft and Glory Hole.

railroad, a considerable saving in time was made, but owing to the high freight-rates charged, the saving in cost of transport was practically nothing. After it was demonstrated that a satisfactory extraction could be obtained in the mill, all shipments of ore were discontinued, with the exception of a small amount of high-

grade sulphide ore, which was, naturally, the most refractory in the mine. Excess freight-rates were charged by the railroad company on all ore assaying above \$300 per ton. This excess rate amounted to 3% of all such excess. Thus on ore assaying \$400 per ton, the excess freight rate was \$3 per ton in addition to the regular freight charges. In consequence, the richest ore was sacked and stored pending the starting of the mill. This ore, amounting to 129 tons, was then run through a five-stamp battery, and over amalgamated plates, and the tailing then run to an empty leaching-vat, in which they were partially drained. After draining sufficiently, they were sacked and sent to the smelter. The original ore assayed 48 oz. gold per ton, and the sacked tailing assayed 18.3 oz. gold per ton. The recovery by amalgamation was therefore approximately 62%. The battery was run on day-shift only, the mill being locked and guarded at night.

This district is now so widely known, and so much has been written of its geology that it is unnecessary for me to go into the question further than to remark, briefly, that the lodes are shattered and fissured zones of silicification formed by hot solutions, under pressure from below, which, following the lines of least resistance, deposited their silica and the accompanying minerals in the zone of fracturing. It is probable that there were other subsequent flows of mineralizing solutions that to some extent concentrated the precious metals in the more fissured portions. In the main workings of the Combination mine, both country rock and lode consist of altered dacite; this is also the case in the Jumbo, Mohawk, and January mines, but in the main workings of the Florence mine, which is situated about 1,500 ft. distant on the southeast continuation of the same silicified zone or vein, the country rock in close proximity to the vein is an altered andesite.

These silicified zones may be regarded as veins, and ore may be looked for either on the foot or hanging-wall side, or even throughout the whole of the silicified mass. As a rule, however, the ore-shoots follow lines of shattering somewhat diagonal to the general course of the silicified zone itself. In the Combination, the general course of the silicified zone is northwest-southeast, while the average course of the richer streaks is nearly north-south. These north-south seams do not extend into the country rock for more than a few feet beyond the limits of the silicification. Where the lode has been rather more shattered than usual and has therefore offered a better channel for the mineralizing solutions, the ore-shoot may include the whole of the silicified material. This occurs in several places in the mine, for instance, immediately adjoining the point of discovery in the shallow 'tunnel,' the ore-shoot is from 30 to 50 ft. wide and about 120 ft. long. Again, on the second level in the split known as the East vein, the silicified zone for a width of over 20 ft. and a length of 150 ft., is one large ore-shoot. Continuing in a southeasterly direction the ore-shoot narrows to a width of four feet of pay-ore and follows the hanging wall of the lode, so that the soft bluish porphyry forms its hanging wall also.

The ore is, as already mentioned, a mixture of soft kaolinized material, with hard dacite in all stages of silicification, from rock showing the original porphyritic structure to dense flinty quartz. The best ore is found in the small stringers and veinlets, already mentioned, that traverse the main body of the lode. In the oxidized portions of the mine—above the 130-ft. level—these are largely filled with small fragments of quartz mixed with a characteristic yellow or reddish ochery material, which is mainly kaolin formed by the decomposition of the feldspar in the original rock. When the sulphide zone is

reached, the rich stringers in the lode are easily followed, as the shattered clayey material is heavily impregnated with sulphides, forming a well-marked dark seam. The richest ore in the mine is usually found on the 'faces' forming the sides of these points, where the gold-bearing solutions have had the best opportunity to precipitate.

The following minerals have been observed in the Combination mine, the names being quoted in the order of their importance. In the oxidized zone: Quartz, kaolin, iron pyrite, gypsum, hydrous ferric oxide, alum, some silvery scales of a mineral that gave blow-pipe reactions for bismuth oxide, and small quantities of a tellurite of iron. Near the water-level: Ferrous sulphate. In the sulphide zone: Kaolin, iron pyrite, marcasite, tetrahedrite, bornite, bismuthinite, and very small quantities of chalcopyrite and zinc-blende. Of these minerals, the tetrahedrite and the bornite are particularly important as being intimately associated with the gold. Free gold is often seen mixed with the cupriforous sulphides, but even when this is not the case, and no gold can be seen under a powerful glass, the specimen will, almost invariably, assay exceedingly rich in gold; from which it is presumed that the gold is either chemically combined with the bornite and tetrahedrite, or else present in a very fine state of division. The appearance of the bismuthinite is no indication of either good or indifferent ore, as specimens have been found showing both free gold and tetrahedrite, and again other specimens, showing bismuthinite and pyrite alone, assay but a few dollars per ton. Similarly in the oxidized zone, no particular change in the value of the ore is noticed when the silvery specks of bismuth oxide appear. The ferrous sulphate is partly mixed with alum and was found on the 130-ft. level as plates with a bluish green color filling the joints of the soft rock forming the hanging wall of the lode. Great care was taken to preserve some of these specimens, but although placed in a tight tin vessel almost immediately, they gradually lost their color, and became dehydrated.

A section of the Combination lode shows the following peculiarities distinctly:

1. Silicification is greatest on surface and is less marked as each succeeding level is reached.
2. Gradual flattening of the vein on its dip, which reaches an angle of 30 to 35° northwest.

The first of these might well be expected in the case of deposits formed by thermal waters followed by only partial erosion. The second, however, is far more of a problem, and it is one that has yet to be studied and satisfactorily explained. The flattening of the vein commenced in the shaft just about the level at which water was first struck—210 ft. At this depth a strong seam came in from the foot-wall side of the shaft, and the ore turned with the wall. Some very rich ore was encountered in the shaft where the splice was made. The greater part of this consisted of partially rounded small boulders of flinty quartz, on the outside of which were concentric layers of the following minerals, in the order enumerated, beginning from the outside: A layer of either marcasite or iron pyrite in botryoidal form; next a layer of quartz with specks of a grayish black mineral, which was later determined as a form of tetrahedrite; and inside this a layer of rusty gold about $\frac{1}{8}$ in. thick. In all the specimens found this order of deposition was observed, and in other places in the mine at which faces of similar specimen ore were found the order was identical. It would therefore seem reasonably certain that the free gold was one of the first minerals deposited.

Very rich ore was found in this mine clear from 'grass roots' down to the bottom or 280-ft. level. Taking it

altogether, however, the richest ore was found between the 180 and 230-ft. levels. Here the vein dipped at an angle of about 45° and consisted of a narrow 'gouge' or selvage of kaolinized material with rounded fragments of quartz heavily impregnated with sulphides. Immediately below this came several inches of the silicified dacite containing stringers and faces of free gold and rich cupriferous sulphide. In many places the rich ore consisted of a rich 'face' only—the rest of the material being low-grade. Underneath this rich seam, the value of the ore dropped immediately to low-grade ore, and sometimes to waste, there being no definite line between them.

As might be expected with such high-grade ore, stealing, or 'high-grading,' as it is generally called, flourishes to an extent unknown in the older mining districts. This is especially true in the case of the bonanza leases, which are worked under high pressure, and where anything in the shape of a delay means the loss of a considerable amount of money. The loss to the mine-owners from 'high-grading' has been estimated at several hundred thousand dollars. This is probably in excess of the true amount, but it must certainly have been very large. Many of the miners that have become expert in the business while working in the mines of Cripple Creek, obtained work in the Goldfield mines, solely for the purpose of stealing ore. These men used to wear a regular harness, to enable them to carry off 40 to 70 lb. of ore on each shift.

In the oxidized portions of the Combination mine, where the richest ore cannot be distinguished by its appearance, panning with drilling water serves to guide the 'high-grader,' and men have been known to 'horn' from 20 to 30 times in a shift. Needless to say, a great deal depends upon the honesty and fearlessness of the mine foreman.

Following the 'high-grader' came many so-called assayers, who ran assay-offices as 'blinds.' Until comparatively recently, it was impossible to do anything to stop ore-stealing. The Miner's Union would not allow change-rooms, and it was impossible to secure the conviction of a man for theft. Since the strike of last December, however, change-rooms have been built at all of the principal mines and several convictions have been secured. This will undoubtedly tend to restrict the wholesale theft of ore.

MINING IN COSTA RICA.—According to a report the following mines have been milling ore during 1906: The Abangarez Goldfields of Costa Rica; the Esperanza Mining Co. (late Boston mine) in the Abangarez district; and the Colburn Mining Co. at Pozo Azul, near Chomes. Development work is proceeding at the Montezuma mine, in the Barranca district, and the Machuca mine, in the Aguacate district. The value of the gold and silver exported was £110,645. The average rate of wages paid to day laborers in the interior has gone up, and now stands at 2s. 4.56d., and in the Limon province, on banana farms and railway work, at 4s. 4.80d. The wages of artisans of all classes have also gone up 20%. This does not, however, indicate any general advance in prosperity among the working classes, since the cost of living has also increased.

TOURMALINE IN CALIFORNIA.—The colored tourmalines of the Pala district, in San Diego county, are well known. The principal varieties are rich, deep-red rubellite, from the Pala Chief mine, and various colored tourmalines, though mainly pink rubellite, from the San Diego Co.'s property, at Mesa Grande.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

In case of unavoidable shortage of cars, a railroad company may distribute such cars as it has to the several mines on its line of road on a percentage basis, calculated on the production of the several mines. The mine owners are only entitled to their proper percentage of available cars; but such distribution cannot interfere with the right of individual owners to the exclusive use of their own cars. And the railroad company may allot an arbitrary number of cars for development to new mines which have no basis for a percentage.

United States v. Baltimore & C. R. Co., 154 Fed. 108. (June, '07.)

A trustee operating a mine under a lease for a term of 50 years, with the right to terminate the lease and remove the machinery if the enterprise should prove unprofitable, was held not liable to a beneficiary for surrendering the lease after prosecuting the enterprise for more than 10 years unsuccessfully.

Mexican Nat. Coal & C. Co. v. Frank, 154 Fed. 217. (April, '07.)

Where stockholders of a mining corporation applied to a court of equity for protection of their rights against the alleged wrongful acts of the directors, they could not recover for failing to act with reasonable diligence, or present some excuse for not having done so.

Jones v. Bonanza Min. & C. Co., (Utah) 91 Pac. 273. (July, '07.)

In an action for the possession of an unpatented mining claim, under a complaint alleging ownership, possession, and right of possession at a specified date and the ouster by defendant of plaintiff, the defendant may show, under a general denial, that the deed under which the plaintiff claimed title was invalid.

Holmes v. Salamea Gold Min. & C. Co., (Cal.) 91 Pac. 160. (June, '07.)

Where a miner was injured by a fall of rock from the roof of a mine in which he was working, it is proper to show, in an action for damages, that the mine was inherently dangerous, and that skillful operators should have known of such condition and taken precaution against it. But it must appear that the conditions at the time of the accident were the same as those at the time to which the testimony related.

Arris v. Standard Plaster Co., 105 N. Y. Sup. 440. (July, '07.)

A mining corporation may issue stock to an attorney in payment for services rendered, and in the absence of fraud, it cannot be questioned by a stockholder.

Bogeler v. Punch, (Mo.) 103 S. W. 1001. (June, '07.)

A mining company has the right to use a stream of water for mining purposes, but it cannot pollute such stream to the injury of a lower land-owner.

Alabama & C. Coal Co. v. Vines (Ala.) 44 So. 377. (June, '07.)

A lease of land for the sole purpose of operating for oil, is not binding on the lessee; and on failure of the lessor to operate for oil, or pay the sum agreed upon in advance, he forfeits all rights under the lease.

Jennings-Haywood Syndicate v. Houssiere-Latreille Co., (La.) 44 So. 481. (June, '07.)

The owner of the legal title to coal underlying a tract of land owned by another is not required to exercise particular acts of ownership over the coal in order to retain title thereto, and, to be divested of his title by adverse possession, the possession must have been continuous and adverse for the statutory period.

Gordon v. Park, (Mo.) 100 S. W. 621. (March, '07.)

The Laist & Tanner Movable Converter Hood.

Written for the MINING AND SCIENTIFIC PRESS
By L. S. AUSTIN.

This hood (patent applied for) is the invention of Mr. Alex. Laist, superintendent of the Highland Boy smelter, near Salt Lake City, Utah, and of Mr. W. N. Tanner, constructing engineer, of Salt Lake City. It is a modification of the Arizona hood and has been carefully designed for effective service.

Fig. 1 is an elevation of the converter, the hood, and its connections. The hood is represented in position to receive the escaping gases of the converter during the blow. Fig. 2 shows at the right-hand edge one of the old hoods, and the ineffective removal of the stifling sulphurous acid gases, while Fig. 3 shows how thoroughly, with the improved hood, these fumes are taken away. Under the old way of working it was difficult to keep men, and the crane-men worked but six hours at a time. As now arranged the converter-house, which is open to the sky, is a pleasant place to work, and the work is more effectively performed. As indicated in Fig. 1, the hood in working position is thrust through a curtain or screen which covers the space just back of the con-

Fig. 1. Movable Converter Hood.

verter (this screen has not been put in in Fig. 3), and thus the blowing about of the smoke by chance air currents is avoided. The hood and square flue (Fig. 1) are in one, and can be slid back when a converter is to be removed from its stand. The joint between the flue and the dust-box is made with flexible asbestos board, held in place by a strap of iron attached to a dust-box, and making a reasonably close joint. When in the backward position, the end of the flue closes off the draft, so that the draft for the other converters is maintained. The flue is mounted on wheels and is moved by means of an air-cylinder operated by the compressed air from the blowing engine at 12 to 16 lb. per square inch.

The air-cylinder is of 12 in. diam., and its piston-rod is directly tied to the bottom of the movable flue. The hood is lined with cast-iron plates, bolted to the interior of the casing, as is well shown in Fig. 3. The dust-box has an outlet to the main common flue of the system, and has an A-shaped bottom with cleaning-doors for the removal of flue-dust. The air-cylinder is beneath this box at the apex of the A. A large part of the flue-dust is caught in a hopper immediately beyond the hood, and is removed as it accumulates. The hood may be moved forward as rapidly as desired, but it is best, in order to avoid shocks, to take about half a minute in so doing.

The writer has particularly observed the performance of this hood, as compared with other designs, and has noted that it is far more effective in that it adds so greatly to comfort in operation. This matter of the

health and comfort of the men is often to too great an extent neglected, and yet an enlightened self-interest shows that it pays out of proportion to its cost.

CHROME iron is found in large quantities in the ser-

the Quebec Central railway, but it is worked commercially only in the Black Lake district. Until recent years no serious operations had been undertaken for its production, but it has been clearly shown that it should take a high rank among the mineral resources of the province.

Genesis of the Ores of Leadville.

By S. F. EMMONS.

*The explanations given in the original reports on the Leadville district of the origin and formation of the ores in limestone have been in many respects very generally misconstrued in subsequent publications. In some of these the writer is assumed to have stated that the ores were brought in by waters descending directly from the surface; in others, that the metallic contents of these waters were derived from the overlying White porphyry, neither of which views he actually held. It would seem that the authors of these publications must have formed their opinion from reading only the preliminary statement, published immediately after the close of field work in 1882, rather than from the more complete explanation given later in the Leadville monograph. In the former¹ it was briefly stated with regard to the origin of the deposits:

1. That they have been derived from aqueous solutions.
2. That these solutions came from above.
3. That they derived their metallic contents from the neighboring eruptive rocks.

In the final report² this statement was made more explicit, as follows:

With regard to the *immediate* source from which the minerals forming these deposits were derived, the following conclusions have been arrived at:

1. That they came from above.
2. That they were derived, mainly, from the neighboring eruptive rocks.

By these statements it is not intended to deny the possibility that the material may originally have come from great depths, nor to maintain that they were necessarily derived entirely from eruptive rocks at present immediately in contact with the deposits.

The facts and reasons on which these conclusions are based will be given in the following chapters.

At the time the preliminary report was in preparation, capitalists were being urged by J. Alden Smith, State Geologist, to sink deep shafts immediately down to the Archean, on the theory that, since ore-bearing solutions came from below, the Leadville ores must necessarily have ascended through fissures in the underlying granitic rocks, and the orebodies found there, being nearer to the source, would be more valuable than those found in the limestone, his belief being that "these fissures and deposits will be extensively and profitably worked for centuries after the contact deposits now operated are exhausted."³

In the light of the geological investigations he had made, this seemed to the writer a mistaken idea, which, if followed, would result in pecuniary loss and might retard the development of the district; hence he made his statement strong, and, as results have since proved, rather too unqualified.

Geological studies of ore deposits up to that time had been, mainly, of veins that follow nearly vertical fissures in the rocks, of which the most natural explanation is that they are formed by ascending solutions; and in ordinary mine reports, for which, as a rule, but little study of the general geology of the district was deemed necessary, the rather perfunctory statement was generally made that the vein materials "came from below," without any very definite understanding on the part of the writer of what these words implied.

It was, moreover, generally assumed, that all waters

circulating within the crust of the earth came originally from the surface, descending under the influence of gravity and ascending again under the influence of heat—either the normal increment of heat within the crust, or that due to proximity with some cooling igneous mass. The modern idea that cooling igneous masses have given off enough occluded water to furnish a continuous underground circulation was then, and for many years afterwards, not considered tenable.

In undertaking the study of the Leadville mines, the writer proposed to take a new departure in making, as a preliminary, a thorough study of the geological structure, not only of the immediate vicinity of the mines but of the whole mountain region within a radius of about 10 miles around, and to base his attempt to explain the manner of formation of the ore deposits on the geological data thus obtained, quite independently of whether the resulting explanation accorded with current theories or not. As it was his first study of any important group of ore deposits, he did not feel competent to go into abstract questions about their origin, much less to present a general theory of ore deposits, as some seem to have assumed he did; hence, in speculating as to the source of the metals, he thought it wiser, as the important object was to furnish a guide to the miner in his search for orebodies (as stated explicitly in the text, Monograph 12, p. 572), "to leave out of consideration altogether the ultimate and purely speculative source and to confine the investigation to the more immediate source, about which it was possible to obtain some actual and demonstrable evidence." Then, after stating that the commonly received explanation for vein deposits is that they have been formed by directly ascending heated solutions, he said: "In the case of the Leadville deposits, the inadequacy and even falsity of this explanation, *except as applied to the ultimate source from which the metals may have been derived*, is readily apparent." He then proceeded to give the reasons for this statement by showing that the form of the orebodies was such as to lead to the conclusion that the ore-bearing bodies entered the limestone from its contact with the porphyry sheets. These contacts being the main channels of circulation and mainly at the upper surface of the limestones, "the few approximately vertical bodies [of ore] that have come under observation afford no evidence that their walls form part of a channel through which the ore currents came up from below;" hence, he concluded, "the above considerations seem sufficiently conclusive evidence against adopting upward currents as the direct source of the ore deposits of Leadville."

In further argument against the necessity of resorting to the unknown depths to find the source of the metals, the author proceeded to give the result of chemical tests of the country rocks, especially those of igneous origin, which showed that small amounts of vein material were found in most of the latter and that most of the varieties of porphyry, except the White porphyry, contained appreciable amounts of silver. Then, without attempting to decide which particular variety of porphyry the metals came from (which he explicitly stated was "too difficult because of the amount that had been removed by erosion since ore deposition") he said: "The foregoing reasons seem to favor the probability that the ores may have been derived, in part at least, from one or more of the bodies of porphyry which occur in the region."

While the intimate genetic connection between the ores and porphyry was established, as he conceived, with reasonable certainty, he admitted that there was still some doubt about the ultimate source of the metals, remarking:

It is possible that in future years, when mine work-

*Abstracted from Bulletin No. 320, United States Geological Survey, "The Downtown District of Leadville, Colorado." By Samuel Franklin Emons and John Duer Irving.

²Mon. U. S. Geol. Survey, Vol. XII, 1896, p. 379.

³Report on mineral and other resources of Colorado for 1881 and 1882, p. 61.

ings shall have been extended over areas where the ore horizon exists at considerable depths below the surface and other eruptive channels have been found and critically examined, evidence may be obtained that ore solutions have ascended along these channels from below.

The idea that was in his mind in saying this was that inasmuch as the Gray porphyry within the mineral area is a distinctly later eruptive than the White porphyry, if the channels were found through which this porphyry had reached the Blue limestone horizon these might prove to be also the channels through which the ore-bearing solutions had reached that horizon.

In the time that has elapsed since the Leadville report was written some of the conclusions have been severely criticized by prominent geologists, notably the genetic connection of ore deposition with igneous eruption and the metasomatic replacement of limestone by ore, but practically all of these conclusions may now be regarded as universally admitted by economic geologists, with the exception of the determination of the source of the metals. With regard to this, it may be said that in treatises on ore deposits written within that time the general opinion seems to be that the writer wrongly conceived the ores to have been brought in by descending waters, but that mining engineers who had become more familiar with the deposits by later and more continuous underground observation had proved them to have been brought up from below by hot ascending solutions.

Having already endeavored to show in what respect the author's statements were misconstrued, it may be well to see how far these statements are justified by a careful consideration of the articles on which they were based.

The mining engineers to whose writings references had been made were Messrs. F. T. Freeland⁵, Charles M. Rolker⁶, and A. A. Blow⁷. Of these Mr. Freeland did not discuss at all the source or origin of metals. Mr. Rolker, confining himself to the direct source, objected chiefly to the assumed statement of the writer that the ore-bearing solutions descended directly and exclusively from the overlying White porphyry, inasmuch as his own observations show that on Fryer Hill, where he had had been in charge of an important mine, the orebodies do not occur exclusively or predominatingly on the upper contact of limestone with porphyry, and that they appeared to have a closer genetic connection with the Gray than with the White porphyry. His general statement with regard to the deposits of the district, however, is as follows:⁸

They are found mainly as contact deposits between the Carboniferous limestone and the overlying felsite, with additional or incidental ore accumulations in the limestone in irregular cavities, directly or indirectly connected with the plane of contact by irregular and often minute conduits, which a careful search reveals.

This statement, as far as it goes, is a confirmation of that of the writer.

In a subsequent article in the same periodical⁹ the writer has pointed out how far the apparent discrepancy of their views arose from a misconception, on the part of Mr. Rolker, either of his statements or of the facts.

Mr. Blow's article, based as it was on nine years' continuous observation of the practical extraction of ore in a part of the region where the orebodies have been deposited to a considerable extent along vertical fractures as well as on the more or less horizontal contacts and bedding planes in the limestone, constituted an invaluable contribution to the geological history of Leadville ore de-

posits, and his conclusions from actually observed facts, such as the origin of manganese in the oxidized ores, and of secondary enrichment, especially of zinc in the upper part of the sulphide bodies, showed remarkable acumen in observation and reasoning. The more theoretical part of his article, relating to what the writer would have called the ultimate source of the metals, is, however, less satisfactory, because, while professedly intended as a refutation of the writer's views, it starts with a misconception of those views, and also because it brings no observed facts to support those which he proposes as a substitute for them.

The misconception consists, first, in his failing to appreciate the fact that the writer was speaking only of the immediate source and declined to discuss the ultimate and theoretical source, and, second, in his mistaken assumption that the writer stated that the metals were derived from the White porphyry. The main part of his argument is devoted to the refutation of this latter mistaken assumption, and is purely negative; but, when he comes to his positive assertions, he simply gives as the alternative source the word 'below,' the use of which the writer had deprecated because of its indefiniteness; and as to the manner in which the solutions reached the present locus of the orebodies, or what the writer would have called the immediate source, he says:¹⁰

That such ascending solutions more readily penetrated the limestone along the planes of contact of the igneous and sedimentary formations, and through zones of least resistance in the latter previously marked out by the intrusion of the porphyries, and gradually replaced the limestone with the metalliferous contents in the form of sulphides.

The writer, in seeking for reasons for the location of the majority of the orebodies in the Blue limestone, states:¹¹

The great intrusive sheets of porphyry are found to follow it most persistently, mainly along the upper surface, less frequently along its under surface, and also cutting transversely across it. These intrusive bodies are also found at other horizons, it is true, but at none so persistently and so uniformly as at this. Thus both ascending and descending currents would readily reach these beds, the latter trickling through the uniformly permeable eruptive rock, the former following up the walls of the channels, through which it was erupted.

Thus, taking into consideration the greater development of orebodies and intrusive sheets of Gray porphyry which had been shown to exist at the time Mr. Blow wrote, the difference in view between him and the writer is not essential, for he does not bring any facts to bear against the latter's third reason for declining to accept upward currents as the direct source of the ore, that is, "the noticeable absence, in the region of greatest ore development, of channels extending downward, through which the ascending solutions might have come." Indeed, in his descriptions he speaks of the ores as going downward rather than upward, and when they occur along vertical fractures he does not suggest their continuation below the Blue limestone, but simply argues against their immediate derivation from the overlying White porphyry, and is apparently no more a believer in Mr. J. Alden Smith's theory than was the writer. Yet the region he treats of is the one region in Leadville where vertical cracks are most frequently found in connection with ores in limestone, and it is upon their occurrence that Mr. Blow founded his theory of northeast shoots as the prevailing form of Leadville orebodies. Hence, the assumption of the various treatises on ore deposits that the writer's theory as to the source of the metals has been disproved by Mr. Blow seems to

¹¹Mon. U. S. Geol. Survey, Vol. XII, 1888, p. 541.

have been founded on an unfortunate misconception of the facts.

On the other hand, with regard to the ultimate source of the metals, it does not appear from his text that Mr. Blow is entirely clear in his mind as to what that source was, or as to the process by which the vein minerals were derived from it. In one place he says¹² that "it does not necessarily preclude the theory that the porphyries were the derivative rock mass from which the ascending solutions receive their metallic contents, * * * to be ejected subsequent to the porphyries, and consequent upon their intrusion;" and later that the "solutions were forced up with their mineral contents from the deep, from the same regions and in the same manner as that of the intrusive dike porphyries with which they are here and elsewhere so intimately connected." Mr. Blow frankly agrees with the writer, however, in admitting that the theory that the solutions came from below is not susceptible of direct proof; hence, the real difference between him and the writer is that the one was willing and the other was unwilling to put forward views in support of which he could bring no facts of observation.

In more recent times, as the knowledge of ore deposits, through scientific studies, has increased, and the more theoretical questions with regard to them have become frequent subjects of discussion, many important changes have been brought about in the views generally held with regard to the origin and manner of formation of ore deposits. It has been actually demonstrated:

1. That deposits in limestone have been formed by directly ascending solutions, of which those of Rico, Colorado, are the most notable instances.

2. That certain deposits in limestone have been formed primarily by direct emanations of mineral-bearing solutions from intruded igneous masses during cooling and consolidation, to which alone the term contact deposits is now considered to be scientifically applicable, since they are characterized by the presence of minerals formed during what is known as contact metamorphism. Up to 1901 there were no published scientific descriptions of such deposits in the United States, but since that time a vast number of important deposits, especially of copper, have been described as properly belonging to this type.

3. That certain deposits, especially of magnetic iron, have been actually formed by magmatic segregation from igneous masses during their cooling and consolidation

4. That underground waters, which are still regarded as the most important vehicle for the transportation of vein material within the earth's crust, are not necessarily all of meteoric origin, as was formerly thought, but may rise from the squeezing out of occluded water from igneous magmas as they cool and contract. That such magmas are giving out water in sufficient quantity to feed thermal springs or to form ore deposits is of course not susceptible of direct proof. It has long been recognized that during volcanic eruptions great quantities of the vapor of water escaped into the atmosphere, but this phenomenon has hitherto been explained as the result of the descent through fissures of ocean waters that came into contact with the rising magmas and thus produced extensive eruptions. Suess, the most prominent advocate of the modern theory, claims that it is not the ocean that feeds volcanoes, but that volcanoes have furnished water to the ocean. Indirect arguments in favor of this theory are found first in the observed fact that in very deep mines the lowest levels are relatively or absolutely dry; whence it is assumed that if surface waters do not reach such comparatively shallow depths they can hardly be

supposed to have been the vehicle which brought the metals up from the barysphere, which must be fifty or a hundred fold as deep, or even to have reached any very deep-seated cooling magma. Second, European geologists, who have been making very long and thorough chemical studies of thermal waters, claim to be able to distinguish among them, by the relative permanence of their chemical composition and degree of saturation, those which are fed exclusively by cooling magmas, or what Suess calls 'juvenile' waters, from those which are fed exclusively from meteoric waters, or 'vadose' springs, or, again, those which are fed in part from one and in part from the other source.

5. Finally, it is generally admitted that the ores as now found in an ore deposit may be the result of a solution and re-precipitation many times repeated, each process resulting in a concentration of its metallic contents. Most important of these, from an economic view, is the secondary enrichment by surface waters. This was noted by the writer in his original report, as applied to the oxidized ores, but it was not then supposed to be possible chemically that it might go on below the ground-water level in the sulphide zone. This has recently been demonstrated, however, by actual laboratory experiments, and the action is recognized as the most important factor in forming the bonanzas of exceptionally rich deposits.

It may be assumed that economic geologists now generally agree, without much qualification, that the limestone ores in the Leadville district were originally deposited

1. From aqueous solutions.
2. In the original form of sulphides.
3. By metasomatic replacement of the country rock.

AGE.—These ores were deposited after the porphyry sheets were intruded and consolidated, but before the dynamic movements which produced the great structural faults of the region. Geological investigations made since the original report was prepared have led to the conclusion that the great preliminary fault-movement may have taken place at the close of the Jurassic period, or previous to the beginning of Cretaceous sedimentation, and inasmuch as it must logically be assumed that the structural faulting in the Leadville district was contemporaneous with that of the Mosquito fault the ores in limestone may have been originally deposited in pre-Cretaceous time.

It is further recognized that a small amount of deformation of the sedimentary beds must have taken place at the time of the intrusion of the porphyry sheets, which produced some slight folding and fracturing of these beds, and thus commenced the localization of the orebodies.

That there has been movement in comparatively recent times along the great structural faults, as was originally stated, has now been definitely proved. Underground exploration has shown that the comparatively recent rhyolitic tuffs and agglomerates are much more widespread in the district than was indicated on the original map. They have cut through and split important orebodies, but have apparently been confined to the region around Breece Hill, and have not affected the limestone deposits in the lower part of the district.

DISTRIBUTION OF ORE.—It was originally assumed, on evidence then available, that the Blue limestone was exceptionally favorable to the deposition and concentration of ore, but it was also stated¹³ "that valuable deposits are occasionally found elsewhere, generally along bedding planes or contact surfaces, and less frequently on jointing planes."

Mining developments since that time have shown that

¹²Trans. Am. Inst. Min. Eng., Vol. XXIII, 1899, p. 181.

¹³Second Ann. Rept. U. S. Geol. Survey, 1882, p. 237.

the predominance of orebodies along the upper contact of the Blue limestones is by no means so great as was originally supposed, some of the most important ore-shoots having been found within its mass at points away from that contact, generally under the sheet of Gray porphyry, but also within the mass of the White limestone. These are locally called second and third-contact bodies, respectively. Orebodies also occur within the Parting quartzite and in the upper part of the Cambrian quartzite. No important and rich ore deposits have been found, however, within the purely silicious beds at the lower part of the Cambrian, nor at the contact of the latter with the crystalline complex or Archean, such as J. Alden Smith thought would "be extensively and profitably worked for centuries after the contact deposits now operated would be exhausted."

It should be further remarked that the important deposits of gold ores in and adjoining fissure veins in the Breece Hill region are not included in the present discussion, which is confined to the limestone ores treated of in the original report, since their genesis is considered to be distinct and more or less independent of the latter, and will be discussed at length in the general report.

As regards the areal distribution of the principal orebodies, it bears an evident connection with that of the later intrusive or Gray porphyry sheets, the details of which cannot be finally worked out until the general geological map of the district is finished. It would appear at present, however, that where these intrusive bodies have distinctly broken up from below, across the sedimentary beds, as have those that form the mass of Breece and Dome hills, the ores in limestone tend to form around the periphery of such masses.

IMMEDIATE SOURCE OF THE METALS.—In considering the source or origin of the metallic contents of the ore it seems well to preserve the distinction originally made by the writer between the *immediate* and *ultimate* sources, although this distinction has been ignored by subsequent writers. General treatises can not go into the minute details of structure involved in a consideration of the immediate source, but must be confined to the broader features in their bearing on general theories. Moreover, few, if any, of their authors have ever visited this district, much less made detailed studies of the geological relations of its deposits. On the other hand, the mining engineers, whose opportunities of studying the details of the orebodies that come under their observation were unquestionably much superior to those of the writer, not being professional geologists and having worked in a relatively limited field, may not have noted the bearing on general theories of all the geological facts that came under their observation.

The determination of the immediate source of the ores is important, even though it may not necessarily affect that of the ultimate source, inasmuch as it furnishes data of practical use to the miner in his search for ore. Thus, in the present case, it would appear that the conception of the authors of general treatises who maintain that the ores were brought in by hot ascending solutions from some deep-seated source is that in their upward course these solutions were stopped by a relatively impermeable barrier, in this case the overlying porphyry sheets, and hence spread out laterally, depositing their contents in the limestone underlying these porphyries. In such a case one would expect to find cracks or fissures extending more or less vertically downward from the respective orebodies which might have constituted the channels through which the solutions ascended directly to the porphyry contact.

On the other hand, if the ore-bearing solutions, in the latter part of their circulation or immediately before

they deposited their contents in the form of the present orebodies, were moving along the contact planes between porphyry and limestone, they could react on the soluble limestone from these contacts outward and form orebodies, either along the immediate contact or at points within its mass, reached through cacks and joints. On this hypothesis, if most of the contact orebodies were found under the porphyry sheet, the prevailing course of the ore solutions would have been downward, and such solutions might have formed orebodies on the upper contact of a lower sheet, because that sheet presented a barrier to their downward course.

As regards the ultimate source of the ores, while the former of these hypotheses is more peculiarly applicable to the deep-seated source, the latter is not inconsistent with the derivation of the metals from either the barysphere or from igneous masses within limited distances of the ore deposits.

Leaving entirely out of consideration, for the moment, the question of the ultimate source of the metals, the evidence as to their immediate source must first be considered, since, from the writer's point of view, that is the only one really involved in the criticisms of his original report. In favor of the first, or what might be called the 'fissure hypothesis,' is the discovery in recent years of deposits coming from or directly connected with vertical fissures in the Breece Hill region, which, however, according to the writer's view, were formed in a distinct and different manner from the deposits in limestone in the lower part of the district, which are now under consideration. In the latter deposits the writer has been unable to find evidence which seems to him conclusive in favor of the fissure hypothesis, or which might not be as readily interpreted in favor of contact and stratification planes as channels for the ore-bearing solutions. Cracks and broken or fissured zones are, it is true, found in connection with some of the limestone orebodies, especially with orebodies that have a decided linear arrangement, such as the ore-shoots on South Iron hill, described by Blow. In a broad, general way, these shoots lie in two prominent or major directions—a northwest-southeast direction, which prevails on Iron and Breece hills, and an east-west direction, which is more prominent in the northwest portion of the district. These apparently correspond to those of the axes of slight folding and fracturing that took place about the time of the intrusion of the porphyry. The structural conditions accompanying these fissures do not resemble, however, those connected with the limestone deposits of Rico, Colorado, which may be taken as the type of those formed by solutions that ascended through fissures. At Rico the feeding fissures contain well-defined and crustified vein deposits. They end upward at a bed of impervious shale that overlies the limestone, but no limit in depth has yet been found. Under the shale, orebodies called 'blankets' spread out horizontally in the limestone, following a zone that is at some places brecciated along the general direction of the fissures. It has been generally assumed in this case that the ores in the blanket deposits were deposited by waters ascending along the fissures, but Ransome, who made the latest and most detailed study of the district, thinks they are due to the mingling of these with solutions that moved laterally along the blanket zone.

In the Leadville limestone only small cracks have been observed in connection with the orebodies. Many of these cracks are traceable upward from the tops of the orebodies to the overlying porphyry, but, so far as known to the writer, do not extend down much below the workable orebodies. A similar conclusion might be drawn from Mr. Blow's description of the Iron Hill orebodies,

for when he prophesies that their extension will be found at a lower horizon, he expects them to go down not vertically but transversely across the stratification, and, as stated above, he believes that the ore solutions entered the limestone along the contacts of Gray porphyry sheets. His improper use of the word 'dike' to denote cross-cutting sheets has given rise to the idea that he supposed the solutions to have risen vertically along actual dikes to the present orebodies.

It is evident that the fractures that cross the limestone have played an important part in fixing the location of orebodies and in furnishing channels along which the ore-bearing solutions may pass from one horizon to another, but the general impression produced upon the mind of the writer has been rather that they served to divert or temporarily to arrest horizontally moving solutions (especially where, as can sometimes be proved, they are the final result of a strain that produced folding) rather than afforded continuous channels for solutions moving directly upward.

The relative superposition of orebodies at different horizons in a given region is, furthermore, such as to suggest that they were formed by solutions that circulated along contacts and bedding planes, and, incidentally, in joints and cracks that crossed the latter, rather than directly upward through a common vertical fissure that fed a series of superposed orebodies.

There is, moreover, an absence of evidence in the mineralogical composition of the ores and wall-rocks that these ore-bearing solutions had temperatures that were high enough to render their direct upward course inherently probable.

ULTIMATE SOURCE OF THE METALS.—The writer does not consider it appropriate in this place to go at length into the theoretical question of magmatic *versus* meteoric waters, which has been abundantly discussed of late in special articles and treatises, an increasing importance being given by many of our best students of ore deposits to the agency of magmatic waters in the formation of ore deposits which may be genetically connected with igneous eruptions. It seems better to postpone the discussion of the broad question of the ultimate origin of the metallic contents of the Leadville ore deposits until the map of the whole district shall have been completed rather than to attempt it in connection with the present description of a comparatively small portion of the area, in which the oxidizing agents have obscured much of the evidence. The original contention that the ores are genetically connected with the eruptive rocks seems abundantly confirmed and even strengthened by the development of the last twenty-five years. That their concentration in exceptionally rich bodies has come about through the agency of surface waters is also confirmed, and the study of the sulphide bodies has shown that this secondary enrichment has not been confined to the oxidized zone, but has extended below the ground-water level. The questions still at issue are:

1. Whether the sulphide ores were originally deposited as a precipitate exclusively from meteoric or from magmatic waters, or in part from both.

2. Whether the magmatic waters, if they were the transporting agents, reached the present locus of the deposits directly from below, or whether they came up along the general channels that carried the magma of the intrusive rocks, and, where this magma had spread out in sheets between the sedimentary strata, whether they followed in general the contacts between intrusives and sedimentaries or penetrated the mass of the latter along cracks and joints before depositing their lode.

3. Whether the deposits, or any part of them, were

formed by contact metamorphism—that is, by waters emanating directly from the cooling intrusive bodies, squeezed out, as it were, from the solidifying igneous mass into the adjoining sedimentary beds.

PREMIER DIAMOND MINE.—The Premier is the largest and most valuable individual diamond mine in South Africa, and it is probably one of the most valuable mines of any kind in the world. It is estimated that when its full plant is at work it will make profit at the rate of \$9,648,000 per year, the life of the mine on this basis being well over 50 years. Considerable interest will be taken in the attempt which is to be made at the Schuller mine to treat blue ground in tube-mills. The diamondiferous ground at this mine will not decompose when subjected to atmospheric agencies, so that it is necessary to disintegrate it by mechanical means. If crushers or rolls be used for this purpose the diamonds, which are brittle, although extremely hard, are broken as well as the matrix, but in the grinding action which takes place in a tube-mill it is thought that the diamonds will be separated from their inclosing minerals without being fractured. Experiments carried out on a small scale point to the feasibility of this arrangement, and if further experiments prove successful, the adoption of tube-mills will revolutionize the treatment of blue ground in diamond mines by doing away with the expensive and tedious process of flooring, which adds both to the cost and the capital expenditure. According to the new Transvaal diamond law, the Government has a right to take up to 60% of the profits of any diamond mines found in the colony, after allowing for all capital expenditure necessary to equip the mine. A law on the same lines has been promulgated in the Orange River Colony, although in this colony the maximum share that the Government can claim is 10 instead of 60%. It is scarcely necessary to repeat that nearly all diamonds manufactured in Amsterdam are of South African origin, and are sold under contract by the De Beers Co. to the syndicate in London. Amsterdam, and all others engaged in manufacturing diamonds being compelled to buy their 'rough' from the syndicate in London. On June 30 last a new contract was entered into between the De Beers people and the syndicate for five years, by which prices of the various series were raised 20%, the syndicate paying for rough diamonds now an average price of \$16.80. The average value per carat of the yield of the several mines last year was as follows: De Beers and Kimberley, \$14.86; Wesselton, \$10.50; Bullfontein, \$10.30; Dutoitspan, \$19.42. The diamonds produced by the De Beers realized \$27,051,627, as against \$23,168,919 for the previous year, an increase of \$3,882,708, this enhanced output being readily disposed of by the syndicate. The demand for diamonds is increasing to a great extent.

THE bulk of the gypsum produced in the United States as well as in foreign countries is manufactured into various plasters, such as plaster of paris, stucco, cement plaster, flooring plaster, hard finish plaster, etc. A steadily increasing quantity is being used as a retarder in portland cement. Refined grades of plaster are used in dental work, also as cement for plate glass during grinding, and as an ingredient in various patent cements. Considerable quantities are ground without burning and are then used as land plaster, or low-grade fertilizer, while smaller quantities are used in the manufacture of paint and paper, imitation meerschaum and ivory, and as an adulterant. The pure white massive form, known as alabaster, is much used by sculptors for interior ornamentation.

The Blow-out.

Written for the MINING AND SCIENTIFIC PRESS
By F. LYNWOOD GARRISON.

The term 'blow-out' is often heard among American mining engineers, especially in the desert regions of the West, and it denotes a geological condition for which we do not appear to possess a more elegant word. Mr. Andrew C. Lawson, professor in the University of California, recognizing this fact has proposed to modify the vulgar 'blow-out' to the more chaste 'blout.*' While I sympathize with him in this attempt to improve a homely English word, it seems to me the danger of not clearly conveying to the reader the thought of the writer, which is the prime object of written language, does not justify a doubtful gain in style. However, as my present object is not to quibble over this question of spelling but to discuss an interesting

A blow-out, as he appears to understand it, is a relatively small narrow mass of rock forming a ridge, rib, or dike, sometimes continuous over a long distance, often broken into detached masses, but always projecting above the surrounding surface of the ground as shown in the accompanying photographs. These protuberances are usually composed of quartz, often pure white, as in Fig. 1, but more frequently of silicified country rock standing out in bold relief by virtue of superior hardness and consequent resistance to erosion. The prospector does not differentiate between a blow-out and a vein, and whatever Prof. Lawson may have seen in any particular

Fig. 1. White Quartz Blow-out, Weaver District, Arizona.

Fig. 2. Blow-out at the Gold Road Mine, Kingman, Arizona.

though not especially important geological subject, I shall employ 'blow-out' until some more appropriate word is suggested.

The origin of the expression is to be sought in the mind of the unlettered but often keen-witted prospector, whose conception of the creation of the earth is derived from the book of Genesis, although he may never have read the remarkable legend that begins the Pentateuch. When a covered porridge pot is over the fire, the steam, seeking to escape, carries with it some of the contents, which, adhering to the outside of the vessel, quickly harden in lumps and ridges. Here we have a phenomenon similar to that which the miner supposes took place in the interior of the earth, when his quartz blow-outs were formed. His conceptions of geological changes are nearly always cataclysmic; such a relatively slow and gentle force as erosion finds no favor in his eyes. Hence, when the prospector encounters great masses of quartz or other hard rock standing out in bold relief from the surrounding terrain he assumes them to be solidified exudences from the molten and seething interior. He appears to distinguish between a blow-out and a lava flow, or the dissected remnants of the latter.

locality it should not be contended that a blow-out may not be a vein or lode. The very existence of a blow-out necessitates some chemical change in the country rock due probably to forces and conditions similar to at least some of those active in the production of ore deposits. While a blow-out may not be metalized to any extent, it is often the accompaniment of orebodies, as for example in the case shown in Fig. 2 at the out-crop of the Gold Road vein near Kingman, in Arizona. The country rock here is granitic and the craggy blow-out of super-hardened rock accompanying this lode can be traced for a long distance. Fig. 3 shows the out-crop or blow-out of monzonite that accompanies the vein at the Techatticup mine at Eldorado Canyon, Nevada. That a blow-out is sometimes ore-bearing and can be mined, is shown by several other photographs in my possession. One is that of a prospect near the Colorado river in northern Mohave county, Arizona. Another illustrates a similar occurrence (in the same locality) accompanied by a rhyolite flow.

In the first case the ore is gold, and in the second copper and a little gold. In this connection it is interesting to observe that the blow-out and veins associated with the rhyolite carry copper, while there is none where there is no rhyolite. I have noted this condition

* 'The Copper Deposits of the Robinson Mining District, Nevada,' University of California Publications. Vol. IV., No. 14, pp. 324-325.

at several other prospects on the River Range in the northwestern part of Mohave county.

Photo 4 is that of a pegmatite or alaskite blow-out in the Weaver district, Mohave county, Arizona. It is actually a large pegmatite lens in schist that has been exposed by the erosion of a water-course. Curiously, it

Fig. 3. Monzonite Blow-out Near the Tschalticup Mine, Nevada.

carries, as do most of the pegmatites of the district, some gold, but not enough to work.

It may be contended that a blow-out is simply an outcrop; this is true, but there appears to be a place for the term as intermediate between outcrop with which the miner usually postulates a mineral vein, and barren common country rock, or a capping of another equally barren associated rock. It implies something out of the ordinary yet not necessarily a vein; a geologist would call it a dike, but it does not always exactly fit into our conception of one, consequently we think Prof. Lawson is justified in his introduction of the word into technical literature, although we may not agree with him as to the spelling of it.

A blow-out is a bas-relief on the geological record, a line in the historical page. Like the history of mankind, the geological narrative repeats itself, but in either case never exactly. Both are records of the ceaseless change and activity of matter constantly taking new forms, no two ever alike.

From time to time amethysts are brought in from places in North Carolina and especially from the region of Rabun Gap, Georgia, on the North Carolina border, although no quantity seems to exist to warrant mining.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

W. J. M., of Octave, Ariz., sends a specimen of Chloritic Schist.

M. M. of Goldfield, Nev., sends a sack of ore, mainly Galena with Chalcopyrite.

The sample from Los Angeles marked G. E. W., is a talcose rock containing copper carbonate.

The mineral sent by W. E. L., of Reno, Nev., is massive Magnetite, which contains no tungsten.

A specimen of Sandstone, stained with iron, comes from Garden City, S. D. It might carry gold.

R. E. F. of Kingman, Ariz., encloses a fragment of Limestone, stained with malachite and azurite.

The blue color of the quartz sent from Nogales, Ariz., by F. W., is due to small needles of dumortierite.

The rock from Manhattan, Nevada, is a crystalline Limestone, with a little quartz. There is free gold showing in the seams.

A piece of Quartz and kaolinized Feldspar banded, probably from a rhyolitic flow, has been received from G. A. L., of Berkeley.

The specimens sent from Naranjera, Mexico, by P. G., are: No. 1, silicified Limestone; No. 2, silicified Limestone; No. 3, Slate; No. 4, Diorite; No. 5, Quartz Diorite; No. 6, Anglesite.

The samples from Ibapah, Utah, marked J. S. L. are:

Fig. 4. Blow-out of Pegmatite, in the Weaver District, Arizona.

No. 1, green Chalcedony; No. 2, Granite Porphyry; No. 3, Mica Schist; No. 4, Chalcocite and Chalcopyrite; No. 5, specular Hematite.

C. E. D., of Beatty, Nev., sends: No. 1, Psilomelane; No. 2, Chalcedony; No. 3, Opal and Jasper; No. 4, Rhyolite; No. 5, Quartz and Feldspar; No. 6, Quartz Porphyry; No. 7, black Hornblende.

The Cuchillo Parado District.

Contributed to the MINING AND SCIENTIFIC PRESS
By R. H. BURROWS.

This place, known formerly as the Colony of Cuchillo Parado, was established during the time of the Spanish domination, in order, with other border settlements, to constitute a check against the tribes of savage Indians that ravaged the northern part of Mexico at that period. The present village is on the Conchos river in the middle of a valley three miles wide, two parallel mountain ranges bounding the valley on the east and west. The plain extends south to the Chilicote plains and northward beyond Coyame. While there is a large amount of land extending along the valley that might be cultivated, the amount planted at present is limited to a small area irrigated by the low ditches brought out of the river Conchos. The land is equally divided among 96 proprietors, who, at the present time, just raise the corn and wheat necessary to support life. Including the village of San Pedro, the production of wheat is about 15,000 bushels per annum with the same amount of corn. Most of this goes out to San Pablo on the Mexican Central; but as soon as the Kansas City, Mexico & Orient Railway reaches the Puerto del Chilicote, which is one day's haul from Cuchillo Parado, everything will be shipped over the latter line. Twenty wagons are employed at the

Sketch Map of Part of Mexico.

present time in carrying out grain and bringing in supplies.

The Aurora mine was worked for lead and silver by the first colonists of Cuchillo Parado, who smelted the ore on the spot, the place at that time being known as the Real of Cuchillo Parado. This name of Real (meaning Royal) was given by the centres of mining activity on account of the old Spanish law, which made all mines Crown property.

The surface ore was lead carbonate, with a good deal of silica and some silver, not very rich. On account of its distance from smelting centres, the mine has been only slightly worked for the last hundred years, being successively located and abandoned by different individuals, some of whom tried to smelt, but the scarcity of fuel and the cost of transportation of the bullion, with its low silver content, resulted in failure. Latterly, the mine was owned by Francisco Diaz, who sold it in 1904 to the Madero Brothers for \$15,000. They formed a company styled the Compania Minera La Aurora y Anexas, and began work in December, 1905, running a cross-cut tunnel that tapped the bottom of the old workings, showing a vein 19 ft. wide of almost solid lead carbonate. Since that time, a winze 160 ft. deep has been sunk below the adit-level, and ore of 40% lead with average of $4\frac{1}{2}$ oz. silver per ton has been shipped from the winze alone, without stopping. This winze shows lead on all sides; the ore has become of better grade in going down, the silica having almost entirely disappeared, the last shipments showing only six per cent.

A most interesting and valuable feature of the mine is the existence of a streak of pure crystalline wulfenite (molybdate of lead), for which they have been offered

\$500 per ton delivered at the Monterrey smelter. The streak of wulfenite varies in thickness from a thread up to two feet. The amount available may be appreciated from the fact that the 160-ft. winze has produced 25 tons of pure wulfenite, worth \$12,500, which is clear profit, as the lead ore taken out of the winze has already paid for the work. While the wulfenite will in all probability yield the greatest profit to the owners of the mine, the most profitable for the railroad will be the lead ore, thousands of tons of about 25% grade now lying on the dump and in the mine, awaiting the completion of the railway to Chilicote, when it is calculated to ship 50 tons per day, which will later be increased to 100 tons per day.

If the ore-shoot holds out, the intention of the owners is to put in a narrow-gauge railway between the mine and the station of Chilicote, 30 miles distant. In this case, coal will be required to raise steam for their railway as well as for power at the mine. The coal required, together with the supplies, will amount to fully a carload per day of freight to bring in to Chilicote, while the amount of ore to take out will amount to at least 50 tons, which in all probability will be later increased to 100 tons daily. The station of Chilicote will become of considerable importance as a shipping point for Cuchillo Parado and San Pedro as well as to the Aurora mine. Numerous zinc and copper prospects occur in the vicinity, some of which will undoubtedly become producers as soon as people find it easy to get into the country and work.

ASPHALT IN TRINIDAD.—For about a century the enormous deposits of asphaltum upon the island of Trinidad have been known, and many widely varying accounts thereof have been published. The asphalt of Trinidad is described as occurring in two forms—land pitch and lake pitch—although there seems to be no fundamental difference between the two varieties. The pitch lake is the original source of all the asphaltum which is exploited in the vicinity of the village of La Brea and between the village and the lake, the land pitch being material which has overflowed from the pitch lake through a crevice in its side and has descended the slopes to the sea. The surface of the lake is 138 ft. above the sea, its area is about 100 acres, and it is nearly circular in outline. The bed of asphalt forming the lake is from 18 to 78 ft. in thickness. The early reports described the material near the middle of the lake as being warm and soft. Now, however, the asphalt is firm enough to support teams at any point for a long enough time to permit of loading. Much water is present in crevices in the asphalt. The lake is thought to occupy the crater of an old mud volcano, and a constant supply of asphaltum is coming into the lake from subterranean sources. Excavations in the lake pitch, and in the land pitch also, fill again with asphaltum in a short time. The crude asphaltum has the following properties: Specific gravity, 1.28; hardness at 70° F, 2.5 to 3; color, brown.

The production of banxite in the United States in 1906 amounted to 75,332 long tons, valued at \$368,311. Compared with the production in 1905 of 48,129 long tons, valued at \$240,292, the production in 1906 has increased 27,203 tons—nearly 57%—while the average price per ton remains nearly the same. A reduction of perhaps 10c. per ton is the average difference noted in the 1906 price as compared with that of 1905. The per cent of increase in tonnage from the Georgia-Alabama district is about even with that of Arkansas, the latter State still leading in production, as it has done since 1903.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

SLIMES-FILTERING APPARATUS.—No. 865,912; David J. Kelly and John M. Callow, Salt Lake City, Utah, assignors to the Kelly Filter Press Co., Salt Lake City, Utah, a Corporation of Utah.

In apparatus of the character described, the combination of a tank having an open end and an annular series of independently-removable and adjustable locking-lugs, a removable head forming a closure for said tank, and means for securing the head to the tank, said means comprising a screw fixed centrally to the head, a rotatable follower engaging the screw, a collar loose on the follower, a series of radially-disposed levers having inner ends pivotally connected to the collar, guide lugs fixed to and projecting from the head near the periphery thereof and between which the outer ends of the levers are slidably mounted, said outer ends of the levers adapted to interlock with the lugs on the tank to secure the head to the tank, and springs acting on the outer ends of the levers to normally hold the latter against the head at the base of the spaced lugs.

ORE-CONCENTRATOR.—No. 865,859; Patriek Brophy, South Omaha, Nebraska.

In an ore-concentrator, the combination of a sludge-box, an endless apron, shafts and sprocket wheels for moving said apron, bevel gears on said shafts, threaded shafts provided with intermeshing bevel gears, said shafts passing through follower blocks connected to said sludge box, said threaded shafts being adapted to automatically lower the sludge box as the concentrates accumulate.

MILL.—No. 863,589; Irénée A. Chavanne and Barthélemy Ollagnier, St. Chamond, France.

A mill having millstones made of hard metal, such as hardened east iron or steel, one of which is driven and pro-

vided with grooves, the other of which and preferably the upper is fixed and provided with a smooth working surface cooled by a water circulation, the said stones being carried by carriers which are provided with distributing furrows the footstep of the shaft carrying the moving stone being adjustable in all directions for allowing of free expansion of the shaft in ease of heating without throwing the stone out of adjustment.

SMEETING PROCESS.—No. 859,132; Frederick T. Snyder, Oak Park, Ill., assignor to Electric Metals Co., Chicago, Ill., a Corporation of West Virginia.

The process of smelting materials containing a compound of a metal which is volatile at the temperature of reduction, which consists in progressively feeding such materials toward a source of heat, continuously removing the non-metallie gaseous products from the surface of the charge, while preventing the escape of the volatile metal therewith, progressively advancing the residue toward the heat and thereafter separately removing the volatile metal at a further stage of the movement.

TUNNELING-MACHINE.—No. 864,704; Russel B. Signafoos, Helena, Mont., assignor to The American Rotary Tunnel Machine & Development Co., Denver, Colo., a Corporation of Colorado.

In a tunneling machine, in combination, a rotary frame, cutters journaled in said frame, means for rotating the cutters, and means for automatically reciprocating said cutters as they rotate.

FURNACE FOR THE TREATMENT OF REFRACTORY ORES.—No. 862,229; Walter P. Wynne and James H. Ballarat, Victoria, Australia.

An improved furnace for the treatment of antimony gold ores and other refractory ores comprising a plurality of furnaces situated at different elevations and provided with fluid-cooled hearths and separate flues and means for feeding the material successively from one furnace to the other.

Improved Plunger Pumps.

An improved plunger pump has recently been placed on the market by the well known pump manufacturers, the Goulds Mfg. Co., of Seneca Falls, New York. The pump is known as a single-acting triplex plunger designed for a working pressure of 130 lb., which is equivalent to a lifting power of 300 ft. The capacity of these pumps for this lift depends upon the size of the plunger. Pumps are made in sizes from 4-in. plungers with 6-in. stroke, giving a capacity of 48 gal. per min. to an 8-in. plunger with 10-in. stroke, giving a capacity of 273 gal. per minute.

The various uses for which these pumps are designed include boiler-feeding, mine-pumping, solution-agitating work, pulp-circulation, and general water-supply for mills and smelters. They are designed for both direct and belt drive and can be furnished with either pullies or arranged for electric motor geared connection.

The general materials used in the manufacture of the pumps are of the best open-hearth steel castings with parts so fitted that they can be readily replaced in a few minutes if disabled. The valves for cold-water pumping are made

Abbé Tube-Mill, Looking From Feed End.

The Editor :

Sir— We have noted our letter which appeared in your issue of July 15, and very greatly regret that through error the cut which was used as an illustration was not that to which we referred in the letter. The cut used shows our Ideal Spiral Discharge, whereas what we desired illustrated

was the Spiral Ideal Feed. We are unable to determine how this error occurred, but assume that the engraver, who was making a number of halftones for us, failed to carry out our instructions correctly.

In order to correct the error made we would ask that you kindly give this letter space in your journal, and that you use the accompanying illustration. It shows some of our tube-mills of recent design.

ABBÉ ENGINEERING COMPANY.

PAUL O. ABBÉ, Secretary.

New York, July 22.

Catalogues Received.

THE LUNKENHEIMER Co. of Cincinnati is sending out a folder describing its blow-off valves.

THE DE LA VERGNE MACHINE Co., of New York, sends us a folder describing its new vertical oil engine.

CHALMERS & WILLIAMS, of Chicago, have issued Catalogue No. 1, Sections J and K, describing the Rapid Cyanide Filter, and Chile mills.

THE CHAIN BELT Co., of Milwaukee, has published General Catalogue No. 35, a handsomely bound, well printed and arranged book of 288 pages, describing and illustrating its line of elevating, conveying, and power-transmitting machinery.

THE DENVER FIRE CLAY Co., of Denver, Colorado, has issued its illustrated catalogue and price list of assayers' and chemists' supplies, including muffles, crucibles, scorifiers, furnaces, chemicals, physical and general laboratory apparatus, etc., making a book of 350 pages that is a credit to its compilers.

THE INGERSOLL-RAND Co., 11 Broadway, New York, send us a 24-page leaflet, which gives a variety of information concerning the various machines for the coal mine manufactured by this company. Ten entirely distinct lines of apparatus are treated of, all up to date and of the highest efficiency in their respective classes.

Single Acting Triplex Plunger Pump.

of rubber discs on bronze grid seats with cylindrically wound springs. For mine use where hot water is encountered the valves are metal wing valves ground to seats. These pumps are kept in stock on the Pacific Coast by Woodin & Little, of San Francisco, who are the agents of the Goulds Mfg. Company.

Editorial.

IN THE OPINION of engineers well informed concerning economic conditions in the West, the prices of labor, fuel, supplies, and machinery, when compared to five years ago, have been so increased as to represent an advance of 30 per cent in the total cost of mining. Any large enterprise run to its full capacity incurs a shortage of labor, delays in freight, and scarcity of fuel. An industrial readjustment is inevitable.

AN ENORMOUS PRODUCTION of lead is coming from the mines of the Cœur d'Alene, but it is not likely that it will be maintained, unless an important new mine is opened up. The Bunker Hill and the Federal group are both diminishing their shipments. A diminution will help the smaller mines by strengthening the lead market. One miner's gain is another's loss, and we like to see the little fellow prosperous.

THE SUBSERVIENCY of the press is well exemplified by the *Graphic*, a wretched sheet published at Los Angeles, which wonders "why Mr. Harriman failed to include Los Angeles in his itinerary during his recent vacation visit west." It is then explained that the "Wall Street wizard hastened east" to meet the directors of the Illinois Central railroad. "But for this incident, Mr. Harriman would have come to Los Angeles, where all of us, his most loyal subjects, would have paid him that homage due to him who holds within his keeping our destinies." Drivel; but true of a certain kind of sycophantic corruptionist, typified by legislators and some editors.

WE PUBLISH a short note on the rapid sinking of a large shaft in the Transvaal. A seven-compartment shaft, 8 feet wide and 39 feet long, was sunk 204 feet in one month, at a vertical depth of nearly 2,000 feet. This record was made by Mr. Charles B. Brodigan, an Associate of the Royal School of Mines—a fact we are glad to chronicle for reasons it is not necessary to state. The previous best was only one foot less, made in 1898, when the Simmer West shaft, 7½ feet by 31 feet, with five compartments, was sunk 203 feet by Mr. Leslie Simson, a graduate from the College of Mining in the University of California—a fact we are pleased to note, for reasons that are obvious. We shall be glad to hear from Columbia, the Tech., Houghton, and other schools of mines, or are they better at deep thinking than fast sinking?

REFLECTIONS concerning the growth of the smelting industry of North America are suggested by the sale of the Grant smelter, at Denver, which is to be dismantled and the site of it used for other purposes.

This will remove a landmark from the outskirts of Denver. The plant was built 25 years ago by the Omaha & Grant Smelting Co., and is named after James B. Grant, once governor of Colorado and still a notable citizen of the centennial State. He was one of the pioneers of an industry that has developed continental proportions. In 1878, just after graduating from Freiberg, Mr. Grant went to Leadville and built a small one-stack smelter at that silver-mining centre, then beginning to boom. Within a year the plant was increased to eight furnaces. In 1880 Edward Eddy and W. H. James, who owned a sampling works, joined him in the metallurgical venture. Later the enterprise became the Omaha & Grant Smelting & Refining Co., with a lead smelter at Denver and a refinery at Omaha. This was the nucleus of a group of smelters upon which the American Smelting & Refining Co. was organized, the Guggenheim plants, at Denver, Pueblo, and Leadville remaining outside as the chief competitors. When they were drawn into the scheme in 1900, it became almost a monopoly, but it was not until several years had passed that the older element became dominated by the Guggenheim brothers. Since then the company has prospered, its watered common stock has been quoted higher than the preferred shares, and the financial operations of the dominant directors have become worldwide; incidentally, the smelting industry has grown apace, so that other companies have been able to get a foothold. Now the Grant smelter is to be dismantled, the 68 acres of land are to be sold to the Rock Island Railroad Co., the tools going to the Globe plant. It may be noted that the Grant smelter has been idle since July 1903 when it was closed down by a strike, which was a good excuse for ceasing work with a plant that was not economical, although profitable, and had become obsolete. "By the wayside of progress lie the broken images of the past."

The Greatest Gold Mine.

IN THE COURSE of a recent tabulation of the gold produced by the richest mines now in operation, we picked the Robinson mine at Johannesburg as the greatest gold mine in operation today. It may interest our readers to consider the following facts: The capital of the Robinson Gold Mining Co., Ltd., is £2,750,000. Milling operations started in January, 1888. Since then 3,212,189 tons have been mined and 2,686,315 tons have been milled. Of the total ore mined, 21.7 per cent has been sorted out. The total working expenses have been £3,552,267 or 26s. 5.4d. per ton. The gold produced has amounted to 2,253,809 oz. fine, and the value of this production has been £9,474,678, or 70s. 6.5d. per ton. The working profit has been £5,922,411 or 44s. 1.1d. per ton. The dividends to the end of 1906 were £5,064,687 and since then £275,000 more has been distributed. At the present time the monthly profit is £65,095 and the yield monthly is worth £95,997. There is a reserve of gold on hand amounting to 23,791 oz. fine, equivalent to £101,100. It is estimated that at the present rate of production the ore actually measurable will supply the mill for

twelve years, that is, the reserves total 4,500,000 tons. As the yield is \$14 and the cost \$5, the profit yet to be won amounts to over \$40,000,000. By the time it is exhausted the Robinson will have yielded a net profit of \$70,000,000. By the end of 1920, this mine will have ceased to be profitable, but long before then the company owning it is likely to acquire new territory, either by purchase or consolidation, so that the life of the enterprise may be prolonged for many years beyond the present known capacity of the mine. The exact amount of ore available is known in this case simply because another company, the Robinson Deep, is working the same lode where the dip carries it across the vertical side-line into the adjacent ground. The operations of this deep-level mine (the Robinson Deep) have afforded an accurate test of the character of the ore at the very bottom of the Robinson; thus the future of the latter is both assured and limited. These facts are sufficiently eloquent without further embellishment. They emphasize the wonderful possibilities of gold mining.

The Crisis in San Francisco.

FROM THE INTERIOR of Eastern Siberia, a mining engineer writes, saying: "San Francisco is to be congratulated on landing the grafters in jail." Similar messages have come to us from South Africa and Western Australia, in fact, from all those distant places into which the ubiquitous mining engineer penetrates in the pursuit of a nomadic calling. The word has been flashed round the civilized world announcing that San Francisco is trying to redeem herself from shame, and the news of an approaching civic rehabilitation has called forth a cheering word from all true men possessed of hope in the betterment of humanity. For the plight of San Francisco is more than a local episode, it is a sign of the times. Californians may be glad to see the city they love asserting her self-respect, Americans may be pleased to note another effort at municipal house-cleaning, but in its world-wide aspect San Francisco illustrates a resolute advance in the evolution of representative government, despite a failure ghastly in its completeness and shameful in its consequence.

Progress is being made. The former mayor, Eugene Schmitz, the first violin of a vaudeville, and a charlatan who exploited the labor party, has been convicted of extortion. Abraham Ruef, an impudent lawyer who acted as advisor and go-between to the mayor and the corrupting chiefs of corporations, has confessed and awaits his sentence. Louis Glass, the general manager of the telephone company that bribed the city officials, has been tried, convicted, and is in jail. Others indicted on similar charges are either undergoing or awaiting trial. There is a probability that a number of unscrupulous leaders of finance and their hirelings will feel the heavy hand of justice. The prosecution conducted by the District Attorney, assisted by a fearless advocate, Francis J. Heney, and supported by a public spirited rich man, Rudolph Spreckels, has succeeded in making the law triumphant. Public opinion has been aroused,

the self-respect of the community has been touched, and the conscience of the people has been awakened. This has given momentum to the wheels of justice. One of the first fruits of the new order of things has been the appointment of Edward R. Taylor to serve as mayor during the few months intervening between Schmitz's conviction and the next election. Mr. Taylor is a graduated physician, the head of a law college, and an author. His administration has won general commendation.

But the crisis has not been passed. On the fifth of November the municipal election takes place. Three tickets have been nominated: Labor, Republican, and Democratic. Ordinary political affiliations do not count; there are three groups, led respectively by labor agitators, spoilsmen, and those, irrespective of party, who want to set San Francisco right before the world. General opinion among professional men, merchants, and reformers favors the election of the present mayor, Mr. Taylor, who has done well under trying conditions. He has been placed on the Democratic ticket and is also receiving the support of an independent movement. Against him are two candidates, an ordinary politician nominated by the Republican convention and an agitator nominated by the Labor party. As the Labor vote at the last election represented 56 per cent of the total, it is obvious that the Republican and Democratic elements favorable to Taylor must be strengthened by some of those that supported Schmitz two years ago. This is likely, for Schmitz and his gang have been thoroughly exposed. Should the labor leader be elected every burglar alarm in San Francisco will go off automatically, for in this City the labor domination is the synonym of municipal debauchery. While the laboring man of America has a freedom of opportunity that is the glory of this Republic, while he has improved the conditions of his life far above his brother in Europe, he has utterly failed as yet to exhibit any civic spirit; he shows only a class spirit, an anxiety to get the sugar plums and to use public office in the interest of his friends. That is what makes the San Francisco experiment under Schmitz so instructive. A democracy ruled by its least intelligent members is no better than an oligarchy of ignorance. Nor is this a sneer against the workman; it is merely the truth about his leaders. We have found by bitter experience that the best workingmen are not the leaders; on the contrary, the more thoughtful are dominated by the irresponsible agitator, who is usually a laborer only in name. Until the working people learn to choose fit representatives, they will be unfit for government. Another evil factor is the public service corporation, that is, the companies controlling the street-car, telephone, water, gas, and electric light facilities of the City. It is to these and to the labor party that San Francisco owes her degradation. The corporation officials made common cause with the labor politicians, until bribery and extortion were rampant and the city's motto might well have been: "An honest man is the loneliest work of God." But honest men are here, they have been ciphers so long simply because they failed to perform their civic duty.

Between the corrupting capitalists, predatory financiers, and unscrupulous exploiters of municipal franchises on the one hand and the venal officials elected by ignorant laborers, gamblers, saloon-keepers, and professional politicians on the other hand, between the corrupting corporation and the corrupted office-holder, is the large body of professional men, merchants, and plain people. The present mayor represents these, so does the present Board of Supervisors (or aldermen), so does the District Attorney and the other members of the prosecution that is bringing criminals to account.

It is a case of the people against the plunderers, it is a contest between civism and incivism, between order and anarchy. In this struggle the better aspirations of a democratic community ought to have the help of the press; they get but little. It is a fact that the daily newspapers of San Francisco are ineffective in leading public opinion, for they are controlled by men without character and edited by men without principle; when they mean to be decent they are only puerile; and when they try to be forceful, they succeed chiefly in being vile. Among the weekly journals, of which there are several irresponsible publications, there was one—*The Argonaut*—that we expected to be the exponent of civic regeneration. Our contemporary has missed a great opportunity to serve the highest interests of this community; to him the effort of the District Attorney's office to enforce the law is a persecution rather than a prosecution, to him the contest between the properly elected law-officers of the community and the criminals that have debauched this municipality is a war between "factions." A similar notion perpetuated the labor troubles in Colorado and Idaho; it is an interpretation that undermines every attempt to apply the law. Criminals always think themselves relentlessly pursued; wrong-doers invariably believe themselves persecuted. San Quentin is full of 'innocent' men.

Despite a reptile press, despite putrid politics, despite the conspiracies of capital and labor, this city of San Francisco is going to assert herself as the exponent of representative government in America. The earthquake did not destroy her, nor the fire; she broke the chains that bound her in dishonor, she shall rise above the mire of politics, to be the forerunner of a better day, to be an example of advanced municipal administration. America as a whole, San Francisco in particular, is going through a crisis due to the rapid development of certain phases of industrial civilization. Corporations and labor-unions are drunk with power. The march of events has been too fast for legal procedure. Lawyers seem to live mainly to impede justice. Public opinion is amorphous. The press is powerful mainly for evil. But these are all phases of a shifting stage of progress. We are having the measles and the whooping cough of representative government. It is an unpleasant but necessary experience. Out of it will come a new order of things, as much better than the ignorant tyranny of an American today as it is better than the queer anachronisms of a European yesterday. We are optimists, for we have been talking with pessimists.

Personal.

ARTHUR L. PEARSE is at Cobalt.
CLAUDE T. RICE is here from Butte.
T. D. MURPHY is on a visit to El Oro.
C. W. PURINGTON is at Vladivostok.
GEORGE A. SCHROTER is in New York.
LLOYD A. WOMBLE is at Reno, Nevada.
CHARLES BUTTERS is in the City of Mexico.
C. B. PRIDE returned to Spokane last week.
HORACE V. WINCHELL is at Wallace, Idaho.
ALFRED VON DER ROPP has returned from Europe.
N. E. LINSLEY has returned to his home in Spokane.
E. M. LAMONT, of Denver, is on a visit to New York.
ROBERT YOUNG has returned to Tacoma, Washington.
E. M. ALDRICH, of Spokane, is in the interior of Alaska.
J. PARKE CHANNING is expected at Breckenridge, Colorado.

DAVID T. DAY is returning from an oil conference in Roumania.

BEN S. REVETT was here this week. He has returned to Denver.

W. A. CALDECOTT has gone to Guanajuato and El Oro, Mexico.

F. W. HOAR has moved from Tombstone to Superior, in Arizona.

JOHN HAYS HAMMOND is very ill at Gloucester, Massachusetts.

S. F. EMMONS has returned to Cananea, after a short stay at Denver.

GEORGE E. JAMME is now at St. Paul and will be at Seattle shortly.

A. M. HUNT has returned to San Francisco from Peyton, California.

M. P. BOSS is engaged in engineering work near Salt Lake City.

WALTER R. CROSBY, of Virginia City, leaves this week for New York.

C. H. MUNRO, of Portland, will leave this week for Colombia, South America.

ARTHUR J. HOSKIN is professor of mining in the Colorado School of Mines.

THOMAS RICHARDS, manager of the Nundydroog mine, has returned to India.

F. C. NEWTON has been appointed assistant superintendent of the Selby smelter.

SIDNEY HANSARD has returned to Seattle from a visit to southern British Columbia.

WALTER HOVEY HILL, who has been in Nevada recently, has gone to Seward, Alaska.

NORRIS ENGLISH has reached San Francisco from Alaska, on his way to Mexico.

C. B. LAKENAN is acting manager for the Nevada Consolidated Copper Co., at Ely, Nevada.

E. W. PARKER was in a train wreck in West Virginia, but luckily escaped with slight injuries.

W. CLAYTON MILLER, general manager for Federal Mfg. & Smelting Co., was in Spokane last week.

F. AUSTIN WILSON, of Boston, is in charge of mining operations in Gunnison county, Colorado.

G. C. KAUFMAN is manager of the mining department of the A. S. & R. Co.'s office at Asientos, Mexico.

EDWARD SKEWES has been appointed mineral agent for Lord Falmouth and will live at Truro, Cornwall.

EARL B. CRANE has recently been appointed general manager of the Trethewey mine at Cobalt, Ontario.

J. CLEVELAND HAAS has an office in the Hyde Bdg., Spokane, where he is engaged in general mining practice.

L. J. CORBETT has opened an office in 501 Empire Bdg., Spokane, to engage in general electrical engineering practice.

FRED WARTENWEILER, now engaged in cyanidation at Phillipsburg, Montana, has been in South Dakota and Colorado.

W. C. BRACE, of Denver, is here on his return from the Dalton mine, in Madera county. He is going to Pioche, Nevada.

EDWARD FINK has left Seattle for Alamos, in Sonora, Mexico, to superintend the erection of a new copper-leaching plant.

NORMAN ROWE, manager for the Guanajuato Power Co., is recovering from a severe attack of typhoid. He was extremely ill at one time.

R. J. KILVERT, for a number of years superintendent of the Golden Fleece mine at Lake City, is now in charge of the Raymond mine at Ohio City, Colorado.

ELY C. HUTCHINSON has been appointed Pacific Coast representative of the Power & Mining Machinery Co., of Milwaukee, with headquarters at 150 First street, San Francisco.

L. W. TRUMBULL, of Laramie, has returned to the University of Wyoming as Professor of Mining, after spending the summer in Colorado and California, and will remain there until January 1.

A. B. CARPENTER, of the firm of Carpenter & Brennon, mining engineers resident in the City of Mexico, has arrived in Oakland on his way to Los Angeles, to establish a branch office in that city.

Books Received.

'Tables of Minerals,' by Samuel L. Pentfield. 88 pages. John Wiley & Sons. This is the second edition of an excellent little book by a first-rate man. The author, lately deceased, was professor of metallurgy in Yale University, and one of the best teachers of science in America. The tables and lists of minerals will be found most useful to busy men. Price, one dollar. For sale by the MINING AND SCIENTIFIC PRESS.

Dividends.

On October 4, the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 121, of \$120,000. This makes the amount of dividends paid since January 1, \$1,740,000, and the total to date, \$9,606,000.

General Mining News.

ALASKA.

The Hadley smelter has started again, for a short run. Improvements in the way of a new hot blast, dust chamber, and heater will be put in. Two new dams have been built to help out the water supply, and a steam shovel, for unloading cargoes of coke and ore, is being put in.

ARIZONA.

GRAHAM COUNTY.

(Special Correspondence).—Engineers report that the New York-Arizona mine at Morenci is showing enough gold-bearing ore to warrant the erection of a mill and reduction works. The new assay office of the company is about completed; as soon as it is in running order, the manager will sample the entire property and make estimates of the ore reserves.—Shipments of ore from the Gold Belt mine have ceased temporarily, and the management will hold the ore on the dump until better prices can be realized for it. Work at the mine continues with a larger force than formerly. The gold and silver in the ore warrant development and give the company the advantage of not having to rely on the copper. At the 200-ft. level, development work is most gratifying, and as soon as the water at this point can be handled, the vein will be prospected. The water in the main shaft is causing some trouble at present, but it will be of great advantage in the operation of a mill, and will save the necessity of pumping from the San Francisco river, several miles distant. The management is looking into the cost of erection of a mill, and as soon as the estimates are completed, provision will be made for its speedy erection.

Phoenix, Oct. 1.

MARICOPA COUNTY.

Prescott men have purchased the Keystone mine and work will soon start.—New machinery will be installed at the Alvarado mine.—The Rincon mill is running one 12-hr. shift per day, and work is progressing on the Marcos property.—The Octave Gold Co. is sinking a 100-ft. shaft on the east end of the Leviathan, the work being in charge of Charles Minetti. There is lots of activity at the main Octave workings.—A. D. Cupples will soon start the stamp-mill on his Gold Dollar property.—Oscar Jennings has resigned his position with the Hale M. & M. Co., to work the Monte Cristo mine that he has bonded. Alex. Spear succeeds him.

MOHAVE COUNTY.

The big mill of the Victor Gold M. Co. at Vivian will be ready to run as soon as the power-plant at Needles is finished.—It is rumored that a large number of the McCracken claims have been jumped.

CALIFORNIA.

AMADOR COUNTY.

Reports state that a 16-ft. vein of good ore has been struck on the 2,600-ft. level of the Gwin mine.—L. L. Cuneo and Frank Burg, who own the Pinevetti mine, near Defender, have run a tunnel 500 ft. and some good samples have been taken from a two-foot vein.

BUTTE COUNTY.

The Pennsylvania dredge sprung a leak last week and sank, breaking the stacker and throwing the electric motor overboard. Men are at work raising the boat.

NEVADA COUNTY.

A good strike is reported from the Union Hill mine, near Grass Valley, on the 300-ft. level. The ore carries gold and lead.—The power line from Colgate to the Alaska mine, at Pike City, has been completed.—The Arctic mine, in the Washington district, has been bonded by O. F. Greeley and E. A. Work, to Sweet, Bacon, and Eckhart.—Some manganese ore has been encountered in the Aurora mine, on Randolph flat.—A Keystone driller has been delivered at Buena Vista, to be used in prospecting Bear river and Greenhorn creek.—A tunnel has been started on the Gold

Bank property at Maybert, owned by T. A. Kohler. A scheme for a long tunnel to develop a group of mines in that district, including the Gray Eagle, Eagle Bird, Bluejay, and others, is being considered.

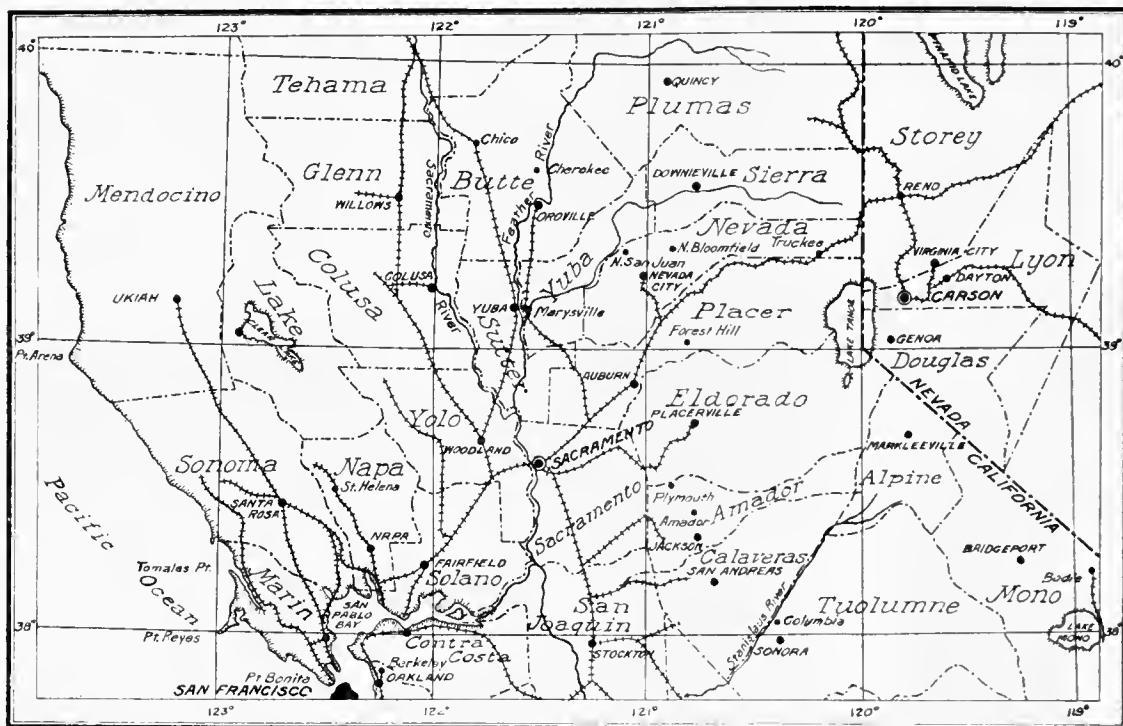

PLACER COUNTY.

At the El Dorado, 14 men are working for David Ray, and 12 are employed at the Home Ticket by A. Dixon. The old Crater mine, which is down about 700 ft., is being unwatered. Fletcher & Rood have a new boiler at the Slope mine, and the shaft will soon be free of water.

SHASTA COUNTY.

The Mammoth smelter is to continue in operation, in spite of the drop in copper. The Mammoth Copper M. Co. is owned by the U. S. S. & R. Co., and Frederick Lyon is the local manager. The Copper Mtn. Con. M. Co. has started hauling machinery from Copley to its Sugar Loaf mine. The new equipment includes an electrically-driven compressor, and air-drills, the Northern California power line having been tapped at the Little Nellie mine. Fred

is in ore. The property comprises 10 claims and has been opened up by 500 ft. of tunnels and drifts. Henry Callahan is superintendent. A short tunnel on the Wellington has disclosed a promising vein of copper and gold ore. At the Bloomfield the main tunnel is in 340 ft. A second tunnel is in 160 ft. Both are in excellent ore. J. H. Adams is manager. A strike has been made in the 80-ft. tunnel on the Copper King. The vein is over 20 ft. wide, carrying gold and copper. The lower tunnel is in 280 ft. and is being driven to tap the main lode at a depth of 350 ft. An 8-ft. vein of ore was recently struck in the upper tunnel on the First National claim of the Joe Creek company. The main tunnel is in 70 ft., in sulphide ore. The main tunnel on the Advance is in 500 ft. Excellent ore is being extracted. The mill is running steadily. A body of ore running \$80 per ton has been struck in the cross-cut tunnel on the Temple & Arbuckle mine. The vein is 8 ft. wide. The company which recently purchased the Beaudry mine is making arrangements to reopen the property. A large force is engaged in laying pipe, cleaning out

Map of Central California.

Grotofend is the manager for the company. J. W. Pinder is the superintendent of the Donkey mine, in the Furnaceville district. The Ingot railroad, to connect Bella Vista with Ingot, is being graded, and the coke for the smelter of the Great Western G. Co., for which M. E. Dittmar is manager, will be hauled over it. There is available at the smelter a six month's supply of coke.

SIERRA COUNTY.

Twenty-five men are employed at the Young America gravel mine, and good results are coming from the clean-up. Eight men are employed at the South Fork mine, where the main tunnel is in 4,700 ft., and rapidly approaching the gravel channel. William McDougall is doing assessment work on the Bald Mountain Extension mine. H. S. Tibbey and Frank Rogers have just completed their annual work on the Secret Canyon and Mt. Vernon mines. Development work will be resumed next spring on the High Sierra mine, once known as the Gold Canyon, which has a vein parallel to the Plumbago. The property is about seven miles above Moore's Flat, and across the river from the German Bar mine, which the Buch brothers are operating.

SISKIYOU COUNTY.

(Special Correspondence). A large amount of development work is under way at the Blue Ledge mine. Over 200 men are on the payroll, and large reserves of copper ore being blocked out. At the St. Albans, the 288-ft. tunnel

ditches, and installing two giants. Three giants, pipes, and other machinery are being installed at the Grouse Creek. Work has commenced on a new tunnel on the Champion, which will be driven 500 ft. Good ore was recently struck in the bottom of the shaft in Tunnel No. 3. The 10-stamp mill is being put in shape for immediate service. O. H. Poor is superintendent. Operations have been resumed at the Johnson mine. The tunnel will be driven 50 ft. farther to tap the main vein. The McKen mine, near Callahan, is shipping high-grade concentrates to the smelters. Much development work is under way. The Scott Bar mine has been bonded by R. A. Murray to Eastern and San Francisco capitalists for \$200,000, to be paid in 12 equal monthly installments. The mill at the Mt. Vernon is running regularly on good ore. A small force of men is engaged in developing virgin country. A 2-stamp mill is being installed at the Ball property. Development work is under way at the Doolittle Creek mine. It is reported that F. H. Dakin, Jr., has decided to purchase the group of claims recently bonded by him.

Yreka, Sept. 26.

TRINITY COUNTY.

Joseph Porter has retired from the management of the Bonanza King mine, and has been succeeded by Mr. Littlefield. About 60 men are employed, and 10 stamps are kept running. A long lower tunnel is being driven to cut the lode at a greater depth. Summer prospecting in the upper

Coffee Creek district is about finished. Wiser & Wommer have run a tunnel 140 ft., treating some ore from an 18-in. vein with a hand mortar. Two *arrastres* are being run below the Nash mine on the Rose and Woodmeier claims.

TUOLUMNE COUNTY.

The small prospecting mill at the Cardigan mine, below Columbia, has been started.—A good vein of copper ore has been struck four miles east of Copperopolis.—The 100-ft. shaft of the North Fork mine is being cleaned out, as are also the Uncle Sam and Driesam shafts. Some good-looking rock is coming from the Duffield claim.—Good ore has been uncovered on the Intevonor and Fleming quartz mines, near the McAlpine.

COLORADO.

GUNNISON COUNTY.

(Special Correspondence).—Near Elko Park, the Empress Mining Co. is shipping ore running high in lead and 30 oz. silver. They have only about 500 ft. of development work on the property.—The Elk Mountain Mining Co. at Irwin is getting ready to ship. The ore carries gold, silver, and lead. About 1,000 ft. of development work has been done. The ore will be hauled three miles to the Irwin switch. M. A. Pennington is superintendent, and F. Austin Wilson of Boston is the treasurer of the company.

Gunnison, Sept. 25.

(Special Correspondence).—McMichaels and Waggner of Pitkin have a contract for driving an adit on the Sandy Hook on Ohio creek. About 150 ft. has already been driven by hand. Power drills are being considered for the property. Adjoining the Sandy Hook on the south, the Belzora-Bassick Mining Co., of which Richard Hightower is superintendent, has recently installed a 20 by 20 in. Norwalk compressor furnished by the Hendrie & Bolthoff company and Leyner Model 6 drills.—Drills are being operated in both the Denver City and Mutual. The adit on the Denver City is in 330 ft. and 600 ft. in the Mutual. The company is doing development work with the expectation of cutting several known veins ahead of them. R. G. St. John is manager.—The Gold Lynx property, which consists of nearly 5,000 acres owned principally by A. E. Reynolds of Denver, is practically closed on account of the volume of water which they are obliged to handle. The water seems to be receding as the fall weather approaches, the summer springs drying up considerably, which it is believed will cause the flow of water to cease. The tunnel is in 3,000 ft. and it is expected work will be resumed as soon as the water subsides. At present they are installing 20 stamps. The stamps will be run temporarily by steam, but it is the understanding that an electric power plant will be installed by the Gold Lynx Co. sometime next year on Quartz creek, near Ohio City. The mill will use amalgamation followed by concentration. Wilfley tables will be employed. The ore is the same character as at the Raymond, which adjoins them on the south. The main tunnel has already encountered five veins on the property and has plenty of mineral ground ahead of it. A concrete floor is being put under the plates and a tank will be placed below in order to catch any amalgam or qulek which may be dropped. The formation on the Ohio creek side is granite carrying gold, while over the hill on the Quartz creek, or Pitkin side, it is limestone formation. The silver is in the contact.—The Raymond Con. M. Co., for which E. M. Lamont, general manager, is working 45 men and running the mill 24 hours per day. Recently a new ore-shoot was opened in the 950-ft. level, which ran from two to seven ounces in gold. They are handling on an average 100 tons per day through the mill. The mill consists of 20 stamps, four Card and four Wilfley tables. O. K. Lewis is resident manager and R. J. Kilvert, superintendent.—The Ashland Mining Co. has been succeeded by the Carter Mining Co., Carroll M. Carter, president and manager. This company is operating what is known as the Carter tunnel. They recently increased their holdings to nearly 700 acres, running clear through the gold belt. The main tunnel is being driven by two Model 6 Leyner drills. The tunnel is now in 3,700 ft. Two Model 5 Leyners are used in the drifts. It is estimated they have

\$458,000 worth of ore blocked out in the upper levels and a raise is being made from the main tunnel to tap it. An encouraging feature is that the ore on the lower levels is higher grade than above. Over \$100,000 has been blocked out on the tunnel level. It is expected they will cut the veins of the Grand Prize and Cortland and afford them transportation facilities. A 14 by 16-in. Leyner compressor furnishes the air for the drills, and 20 men are employed at present. No ore is being shipped, but it is the intention of the president to soon erect a mill to handle the ore. The company is capitalized at \$450,000. The Grand Prize on Carter Mountain in Jones' Gulch is shipping two to three cars of ore per week that nets over \$100 per ton.

Ohio City, Sept. 25.

NEVADA.

ESMERALDA COUNTY.

Goldfield shipped more ore during the week ending Sept. 27, than in any previous week in the history of the camp. The total was 4,129 tons, estimated to be worth \$400,000. The smelters received 590 tons: the Nevada Goldfield Reduction Works, 1,651; the Western Ore Purchasing Co., 1,418; and the Combination mill, 560 tons. The Mohawk Jumbo lease on the Jumbo Extension contributed largely to this production, but the Little Florence and the Mohawk Combination were doing development work and were not heavy shippers. During the week, the Nevada Goldfield Reduction Works received ore as follows: Mohawk mine, 546 tons; Mohawk Combination, 368; Red Top, 210; Little Florence, 277; Jumbo dump, 250. Value, \$165,100. The Western Ore Purchasing Co. received consignments of ore as follows: Mohawk Jumbo, 1,185 tons; St. Ives lease, 32; Hayes & Monnette dump, 68; Little Florence, 143. Estimated value, \$141,800. The Combination mill treated 560 tons of ore that ran \$80 per ton and the Mohawk mine shipped 500 tons of \$100 ore to Miller. Some high-grade ore is being taken from the Codd lease on the St. Ives. The vein is six inches wide.—The Florence L. & M. Co. has let a contract to sink its shaft from the 385 to the 455-ft. point. From the bottom a cross-cut will be run to tap the junction of the Reilly vein and the vein running through the leased ground.—The shaft of the Mohawk Red Top Lease Co. is down 300 ft. and it is expected to cut the Red Top vein at the 450-ft. point.—The Mohawk Combination lease has cut some good ore in the north cross-cut on the 206-ft. level.—A station is being cut on the 450-ft. point of the Laguna, and connection will be made on that level with the Red Top workings, by means of a drift and raise. Later, connection will be made with the Mohawk workings.—The Consolidated company has ordered a 150-hp. engine for the Mohawk, and the main shaft will be sunk to a depth of 1,000 ft. The working shaft of the Combination will be enlarged.

NYE COUNTY.

Tonopah shipped 5,952 tons of ore over the Tonopah & Goldfield railroad, during the week ending Sept. 26. The shipments as reported by the Western Ore Purchasing Co. were as follows: Tonopah Mining Co., 1,812 tons to the smelters and 2,520 tons to the mill at Miller; Tonopah Extension, 153; Jim Butler, 73; Midway, 54; Belmont, 50 tons to the smelter and 1,290 tons to the mill at Miller. In addition to the above, the Montana-Tonopah treated 956 tons at its mill, which amount is not included in the total shipments. The Liberty district shipped five tons.—All 40 stamps of the Montana-Tonopah mill were dropping, for the first time. This was done by using steam at the mine and switching all the electric power to the mill. Probably 20 stamps will have to be hung up again, as the Nevada-California Power Co. has not water enough to make the required power.

(Special Correspondence).—The prospecting shaft on the property of the United Mines Syndicate, eight miles east of Rhyolite, has reached a depth of 155 ft. Much water is being encountered. A 15-hp. hoist was erected July 1, and commenced operations at the 100-ft. level. Sinking was continued until water was struck at 145 ft., making it necessary to close down until a Cameron pump could be installed. This pump is in operation, being run by compressed air. The orebody will be cross-cut at the 200-ft. level,

and sinking continued at the same time. If the present favorable indications continue, when a depth of 250 ft. is reached a double-compartment shaft will take the place of the present one and a compressor will be installed. The officers of this company are: W. E. Sharon, of Nevada City, president; E. B. Cushman, treasurer; W. C. Russel, and J. J. McSorly.—The vein in the Denver mine of the Tramps Consolidated is reported recovered at the bottom of a 200-ft. winze, and at a vertical depth of 450 ft.—The Montgomery Shoshone is shipping 150 to 200 tons per week. The mill, recently erected, is only awaiting the arrival of the electric power to commence operations, the same having been promised by Sept. 15.—A carload of ore was recently shipped to San Francisco from the Homestake-King, to determine the proper process of reduction. As soon as this is decided upon, a 100-ton mill will be erected at the mine.

Rhyolite, Sept. 20.

At the mines of the Tonopah Mining Co., work is being steadily carried forward. Stoping is going on in the eastern end of the Mizpah vein, on the 200 and 300-ft. levels, and will soon be started on the 400 and 500 levels. On the 300-ft. level, an exploratory cross-cut is being run. In the Silver Top mine, formerly known as the Valley View, stopes are

Map of Eastern Nevada.

being carried on the upper five levels, and driving is in progress on the 600 level. The Red Plume shaft will soon be in operation.

WHITE PINE COUNTY.

The French syndicate, represented by E. L. Labadie, which took over the Buena Vista and White & Shiloh properties at Galena, will soon begin work. The deepest of the old workings is 200 ft. down, and the new organization proposes to go down 1,000 ft. Several other properties in the district have been acquired.—Three shifts are sinking in the Giroux Alpha shaft, which is down 1,000 ft.—The concentrator at Kimberly is running.—Some good ore was recently struck on the 500-ft. level of the old Harris mine, near Washoe. The vein was cut by a tunnel and is about four feet wide.

Charles C. Gates, manager for the Nevada United Mines Co., reports work progressing favorably at the old Martin White mines at Ward. The new shaft is down 125 ft. and lead ore is coming in. A cross-cut will be run from the 300-ft. level of the Paymaster, to connect with the Good Luck shaft. The Willow creek dam will soon be finished and water-power will then be available. Thirty men are on the payroll.—The shaft on the Nevada Gold Coin property at Golconda is down 75 ft. on the vein. A 5-stamp

mill has been erected and a new hoist set up.—The pipe line of the Giroux Consolidated mines, from Steptoe creek, is progressing. W. E. Walters is manager for the company.—Robert Baird is manager of the Success mine, on which the shaft is 300 ft. deep. Some lead ore has been exposed.—The improvements that have been in progress at the Pittsburg Ely shaft have been completed, and sinking and development work can now be carried on expeditiously. The shaft is down 60 ft.; Charles A. Straub is the superintendent.—The Ely Standard Copper Co. has purchased the Duzette group of claims near Lane City.—Charles Reese and H. Hawks, who leased the Independence mine, are milling the ore at Campbell's mill, 10 miles distant.

WASHINGTON.

OKANOGAN COUNTY.

(Special Correspondence).—At the Allen placers, on Mary Ann creek, over 500 cu. yd. of dirt has been washed.—At Chesaw, the Ben Harrison Mining Co. is operating on the 100-ft. level. Ore is being stoped and sorted for shipment.—The Molson Mining Co. is employing 25 men on the Poland China group and expects to double the force. A glory-hole has been started, and rich ore is being mined. The mill has been started.—The Jumbo Mining Co. will start operations on a group of claims in Beaver canyon, southeast of Chesaw. Among other improvements, a mill is in contemplation.—The Grant Consolidated is employing 25 men and operating machine-drills in the lower adit.—The Tamarack company, operating about two miles northeast of Chesaw, is sinking on a vein of rich ore.—The Butcher Boy adit is expected soon to cut through to the shaft on the 100-ft. level.—Operations will be resumed on the De Lait group, two miles north of Chesaw, as soon as J. J. Bennett, the newly appointed manager, can get men.—A quantity of galena was struck in an open-cut on the Deerfly group, on the summit of Copper Mtn., east of Chesaw. The group, consisting of four claims—the Deerfly, Bull Swede, Small Hope, and Diamond Drill—is reported to have been bonded to an Eastern company for \$150,000.—A 500-ft. adit has been completed on the Methow Bell group, near Twisp. The property has a splendid showing.—Work on the Wolverine group, at Camp Gilbert, is to be pushed.—Molybdenum deposits discovered last summer at the head of the Ashinola river, near the British Columbia boundary line, are attracting widespread attention. The assay values of samples of the ore run from about \$30 to \$176 per ton, and parties are trying to bond the claims. Locators of two adjoining claims were offered \$2,500 each for their locations, and have sold them, subject to investigation.

Republic, Sept. 22.

STEVENS COUNTY.

(Special Correspondence).—Wonder air-drills are being used in the United Copper mine, in Chewelah district. The company is driving on the vein, on the main adit level, and getting out a good grade of copper ore for daily shipment.—The Manchester Mining Co., on Stevens Peak, is driving an adit. It is in 890 ft., has intersected seven stringers, and is expected to strike the main vein soon. A contract will be let to drive another 100 ft.—The Napoleon mine, owned by the British Columbia Copper Co., has been temporarily closed down, owing to the lack of coke at the smelter. The ore-bins are full.—In the Chief & Butte mine, a 12-ft. vein of ore, carrying copper, has been intersected in an adit, about 200 ft. from the portal, and the working force has been increased. Three veins crop at the surface, and the adit will be driven farther. Three shifts are employed.—Copper ore has been encountered in the lowest drift from the shaft on the Copper Butte mine. There is a strong showing of chalcopryite in the rock.—Ore-bins of 4,000 tons capacity are being built by the Globe Mining Co. A three-mile wagon-road is under construction from the mine to the railway, at Orient, to be finished by Oct. 1.—Work on the shaft at the Regina mine was stopped until a fan could be put in. It is expected operations will be resumed early in November and that machinery will be installed.

Republic, Sept. 28.

BRITISH COLUMBIA.

There has been a marked increase in the smelter production. Five out of the seven furnaces at the Trail smelter are in operation. The following is the record of tonnage shipped from the Rossland mines during the week ending September 21: Centre Star, 3,780 tons; Le Roi, 1,925; Le Roi No. 2, 560; White Bear, 140; Nest Egg, 29 tons. Total 5,405 tons or a total of 193,592 tons for the year to date.—Ore is being stoped in the Idaho property of the Centre Star, it being taken out through the fourth level of the Centre Star mine. The sixth level of the Centre Star, on which but little work has been done recently, is being pushed into the Idaho, to intersect the ore at a lower level. Ore is also being stoped on the first and second levels of the War Eagle, and the Iron Mask is producing.—At Le Roi, diamond-drilling continues in the Spitzee. In the Le Roi mine, exploration continues west of the Josie dike.—The development of level No. 7 continues at Le Roi No. 2.—Work on the California and Giant tunnels and on the vertical shaft, is being pushed.—Development continues at the Inland Empire, and the Nest Egg lessees shipped a car of ore during the week.

At the Trail smelter, in addition to Rossland ore, ship-

low-grade, and a large amount of zinc ore has been developed.—The Sailor mine will be unwatered, a tram constructed from the Sailor shaft to the Minnie mill of 10 stamps, and a pipe-line laid from Rice creek.—The new air-compressor at the Crescent mine is in operation.—The annual meeting of the Providence Mining Co. will be held in Greenwood early in October.—Contractors have finished the raise from the Granby Curlew tunnel to the intermediate level, thereby improving the ventilation of that part of the mine.

MEXICO.

SINALOA.

C. F. Whittier and Isaac Bryson, of Los Angeles, have taken over La Palma mine in the Rosario district; the ground adjoins the famous Tajo mine of the Bradbury family, and has been worked for years by natives.

SONORA.

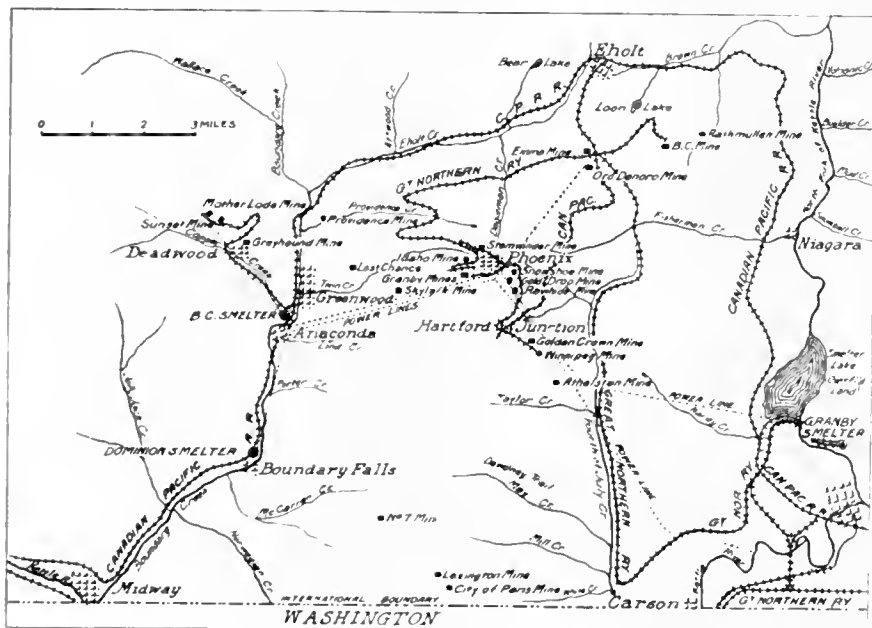

The Tomlinson & Norton Mining Co. has been organized in Cananea to take over the San Augustine group, also known as Los Guijas, about 20 miles below the Chispas. The property, which was purchased from Jesus Carrillo and Antonio Acuna, has not been worked for 23 years; 3,000 ft. of workings stand open. A 10-stamp mill and cyanide plant has been ordered.—

Work is progressing in a satisfactory manner on the Fundicion smelter of the Douglas Copper Co., which will be blown in about November 1. With the first unit of this smelter in operation the company will treat 250 tons of ore per day at an estimated cost of \$12 per ton. The ore is reported as valued at \$34 per ton in copper, gold, and silver. As the ore runs 6% copper, the output will be 9,000,000 lb. copper annually at a cost of 10c. per lb. It is estimated that this company has enough ore already blocked out in its mines to keep the smelter going for five years.—N. C. Banks is the manager for the Black Mountain M. Co., at Cerro Prieto.

An important discovery was recently made in the lower Limestone tunnel of the Phelps Dodge Indiana Sonora, when ore was struck 150 ft. in the Sierra de Cobre.

At the Campana shaft, the foundations for the new pump have been completed at the 800 station and the pump is being set.—On the fourth floor from the tunnel level in the Democrata, some fine malachite has been opened. The winze from the 500-ft. level is going down in ore, and a third compartment in the shaft is being provided for by raising.—Charles McHenry, superintendent of the South Cananea, has received orders from the New York office to keep the pumps running and the property opened. Negotiations are under way in London for financing the new company recently organized to handle the property.—Ore has been encountered in the tunnel on the Native claim of the Ortega. Work on the rest of the property is stopped, pending the arrival of pumps for the shaft.

The management of the Greene Cananea has decided to temporarily curtail production, which will probably mean that stoping will be confined to the mines of Capote basin and Cananea Central properties. Elisa and Puertocitos furnish desirable fluxing ore, and will probably not be affected.—The Ortega tunnel on the Native claim is still in ore.—Five shafts are being sunk on the Cananea Nueva property. Encouraging reports are heard from the Arizpe Development Co.'s property.—At a recent meeting of the Cananea Eastern M. Co., the old directors and officers were re-elected.—Development continues in a satisfactory manner at the Santa Cruz copper mines, 30 miles southeast of Nogales, toward Cananea. A good showing of ore is reported.

Part of British Columbia.

ments from other mines were as follows: Snowshoe, Phoenix, 1,838 tons; St. Eugene, Moyie, 86; Vancouver, Slocan, 22; North Star, East Kootenay, 48; Ryner, 20; Slocan, 23; Arlington, Erle, 22; Standard, 26; La Plata, 89; Hewitt, 21; Montezuma, 22; Grizzly, 28; Whitewater, 71 tons.—At Northport there was received during the week 1,925 tons of ore from the Le Roi mine.

The Boundary district made a heavy shipment during the same week, the ore being distributed as follows: To Granby smelter from Granby mines, 23,180 tons; from Emma mine, 580 tons. To B. C. Copper Co.'s smelter from Mother Lode, 5,246; from Snowshoe, 2,560 tons. To Dominion Copper Co.'s smelter from Brooklyn, 1,509; from Idaho, 1,216; from Rawhide, 3,591; from Sunset, 1,396; from Mountain Rose, 254 tons. Total shipments for week, 41,734 tons and for year to date, 885,997 tons.—Boundary smelters during the week treated as follows: Granby smelter, 19,622; B. C. Copper Co.'s smelter, 8,881; Dominion Copper Co.'s smelter, 7,968 tons. Total treatment for week, 36,471 tons, and for year to date, 867,353 tons.

Summarizing the shipments from southeastern British Columbia for the week shows the Boundary district sent 41,493 tons; Rossland, 7,112; and East of the Columbia river, 2,782. The smelter receipts were: Grand Forks, 23,760; Greenwood, 7,786; Boundary Falls, 7,968; Trail, 6,526; Northport, 2,171; Marysville, 600; total, 48,811 tons of ore.

The Cariboo mill, in Similkameen, has been overhauled. Thirty men are employed in mine and mill. The ore is

Special Correspondence.

Butte, Montana.

Decrease in Copper Output.—Statistics for September.—Butte Central & Boston.—The Lexington Mine.—Barnes-King Affairs.—Subduing an Underground Fire.—The Snowstorm.—Local Stock Depression.

The reduction in the Butte copper production, which began in July, reached a little more than 60% in September, and the total output for the month was little more than 11,000,000 lb., compared with the normal production of 28,000,000 to 30,000,000 lb. per month. During the last week of the month there were no further reductions in the working forces at the mines and smelters, but the big companies were prepared to make a still further reduction, or close the mines entirely, if necessary, to bring about an improvement in the metal market. The estimated production in September was 11,329,800 lb., from 172,200 tons of ore. The total ore tonnage and copper production credited to the various companies were as follows:

Companies.	Tons of ore.	Pounds of copper.
Boston & Montana.....	30,000	2,040,000
Anaconda.....	36,000	2,160,000
Butte & Boston.....	7,500	457,500
Washoe.....	4,800	292,800
Parrot.....	6,000	348,000
Trenton.....	5,400	324,000
North Butte.....	18,000	1,440,000
Coalition.....	24,000	1,608,000
Original.....	27,000	1,647,000
East Butte.....	6,000	450,000
Pittsburgh & Montana.....	4,500	337,500
Miscellaneous.....	3,000	225,000
Total.....	172,200	11,329,800

Very few of the new developing companies have been compelled to shut down on account of the low stock market and scarcity of money for mining purposes, and the indications seem to be that all will be able to weather the storm. The Butte Copper Co. is the only one that has entirely suspended development work, though it had long ago lost the confidence of the majority of its shareholders by the unexpected reorganization about a year ago.

The Butte Central & Boston Co. has about 15 sets of lessees at work in the Ophir mine, a number of first-class men having sought leases since the decrease of work at the big mines. No ore was shipped from the Ophir during September, but during the latter part of the month a great deal of development work was done. One set of lessees on the 500-ft. level have opened a fine body of ore west of the shaft and main cross-cut. The ore-body is six feet wide and has been opened by drift about 20 ft. In driving the drift they have broken down 15 to 18 tons of ore per day, which they expect to increase to 50 tons when they begin stoping. The ore assays 45 oz. in silver and \$3.20 in gold. Another set of lessees are sinking on an orebody on the 300-ft. level on the east side of the cross-cut. On the same orebody one lessee took out about \$40,000 worth of ore from the stopes, but the pay-streak pinched out. Other lessees are now raising from the 300 to see if they can not find the rich shoot again. On the 500-ft. level the company is driving a cross-cut and has advanced 36 ft. in the south vein. The vein carries some streaks of ore, but nothing of any account. In the opinion of Manager Cameron pay-ore will be found near the hanging wall. The vein is estimated to be about 70 ft. wide at that point.

The Lexington mine of the La France Co., which is also a silver producer, had to curtail its output on orders from the smelter because of the large percentage of

copper the ore carries. Then, because of the suspension of operations at the Corra mine, from which the Lexington derived its air, it had to close altogether. The La France Co. is now engaged in installing an air-compressor of its own at the Lexington mine and expects to be in shape to resume production in a few weeks. The company laid off about 75 underground men, but is employing about 85 on the surface in construction work on the new concentrator and separator plant. This work is being pushed as rapidly as possible and the company hopes to have the plant in operation early in November. It will include a dryer, crusher, concentrator, and separator. The Lexington has never been hindered by the strike of machinists as their demands for an increase of wages were granted.

John Gillie and C. W. Goodale of the Barnes-King Development Co. have been at Kendall making an examination of the company's mines, and will make a detailed report to the stockholders, the report to cover not only the condition of the property and of the treasury, but also the financial history of the flotation and transfer of the mines to the company by the promoters, regarding which there have been some ugly rumors. It has been claimed by independent experts that the promoters' reports, under which the company took over the property, proved incorrect, and that the property did not cost within some hundred thousand dollars the amount represented to the company. However, Mr. Gillie says the mines are good and their condition satisfactory, and that the payment of dividends can soon be resumed. Because of the adverse reports and the exposure of the former management many stockholders lost confidence and have been selling their holdings all the way from \$5 down to \$2 and \$1.90 per share.

The Boston & Montana and Butte Coalition companies are still trying to subdue the fire in the old Leonard mine, the gas and smoke from which has stopped work in a portion of the Minnie Healey mine and compelled a shut-down of the Leonard and West Colusa. It is believed that the fire will be absolutely under control by the time a resumption of operations at all the mines, which have been closed as a result of the copper curtailment policy, is ordered. The Boston & Montana Co. is sinking an up-cast shaft right over the fire, which is burning on the 600 and 700-ft. levels, and has also secured permission from the Butte-Montana Co. to sink the Alex. Scott shaft 200 ft. deeper and drive a cross-cut from the 1,200 ft. point to get under the fire. It is the object to clear the mines of all the gas and then wall in the fire, confining it from the top, bottom, and sides, as has been done with the fire in the St. Lawrence mine of the Anaconda Co., which has been burning constantly since 1889. The fire in the Leonard has been the most stubborn the mining companies of Butte have ever had to contend with, and its effect on operations is especially serious because nearly all the mines in that part of the district are connected by numerous workings.

The Snowstorm mine at Mullan has made net earnings of \$498,013 during the last fiscal year, and of that sum \$359,910 was paid out in dividends. Notwithstanding the earnings and dividends, the stock of the company has gradually declined from about \$5 per share to \$1.90. During the past year, according to a statement by W. D. Greenough, the manager, the mine produced 87,503 tons of ore, of which 77,782 tons were shipped direct to smelters and 9,721 tons were treated at the company's leaching plant.

General financial and mining stock conditions have had their effect on the local Stock Exchange, and quotations have gradually declined during the past year. Butte & Arizona dropped gradually from \$3 to 31c. per share,

notwithstanding the better condition of the property. Other stocks have dropped in the same proportion. Butte & Bacorn declined from about \$1 to 12c., and the public, which has been badly bitten by such local mining stocks as Butte Copper Exploration, Barnes-King, and Butte Copper, has entirely dropped out. It will be a long time before confidence is restored.

Mexico City.

Presidential Message Before Congress.—Principal Features of Speech by Diaz.—Prosperity of the Country.—Development of Mining.—Failure to Merge Railroad Companies.

On the evening of Sept. 16 the third period of sessions of the 23rd Congress of the Republic of Mexico was formally opened in Mexico City by the annual message of President Diaz delivered before the combined assemblage of senators and deputies, and while the message would prove interesting to the readers of the MINING AND SCIENTIFIC PRESS, space does not permit of quoting

the whole of it, but there are portions of the message of sufficient importance to those who are interested in Mexico that it would seem a neglect not to give the substance of such portions in this letter. The President stated that "the various controversies which naturally arise between neighboring nations like Mexico and the United States have been adjusted of late in a spirit of genuine harmony and good-will on the part of both Governments, demonstrating the stability and cordiality of the relations between the two countries. * * * Labor troubles have not ceased altogether, but the demonstrations have diminished considerably both in frequency and intensity—so that in general there was no occasion for the authorities to act in order to put a stop to them or to prevent perturbations of public order. * * * The Geodetic Commission has, in the south of the country, completed the accurate scientific work necessary for measuring the 98th meridian of longitude west of Greenwich * * * and has concentrated its outfit in the north of the Republic, selecting vertices on the plains of Tamaulipas right up to the boundary line with the United States, where its operations will be carried on in conjunction with similar work in the neighboring republic, by virtue of an international agreement between the two countries. * * * Arrangements have been made by the Geodetic Commission to draw up a magnetic chart of the Republic. * * * The Sonora Scientific Commission has completed a wagon-road between the town of Torin and the nearest station of the railway from Guaymas to Guadalajara. * * *

The steady development of the mining industry is worthy of note. From the beginning of January to the end of June of the present year there were issued 2,600 title-deeds to mines embracing 10,698 pertenencias (100,000 acres) as against 2,000 deeds for 30,650 pertenencias (75,000 acres) during the preceding six months. * * *

In the second half of the last fiscal year 20 contracts were entered into for the utilization of watercourses under Federal jurisdiction of an aggregate volume of 589,300 litres per second and 36 title-deeds were issued either confirming old water-rights or in connection with new concessions. * * * The new construction of railways subject to Federal jurisdiction aggregates 277 kilometres

(173 miles), the largest being those from Columbia to Jarita (the coal beds near the Texas line), the Pan American from Ocotlan to Atotonilco, the Cananea, Rio Yaqui & Pacific, and the line from Navajoa to Guadalajara. Additions to other roads aggregate 207 km. (129 miles). The total length of the railway system in the Republic is 22,392 km. (13,995 miles). The earnings of the Tehuantepec National Railroad from January to June last as compared with the same period of the previous year have shown an increase of 265 %.

* * * The Federal revenue collection for the fiscal year 1906-7 shows a surplus of over P20,000,000, the total receipts being P11,000,000 in excess of the previous fiscal year. And in consequence a material reduction in the stamp tax and other Federal contributions went into effect May 23 last, proving the Government's solicitude in behalf of the tax-paying classes. * * * Mexico had, up to four or five months ago, succeeded in keeping out of the influence of the disturbing financial factors, but scarcity of available funds has arrested the invest-

Sinaloa and Part of Sonora, Mexico.

ment of foreign capital in the country, obliging the banks to strengthen their holdings in cash and refuse aid to new undertakings except of undeniable solidity.

* * * The monetary situation is improving, the new gold coins increasing from P60,000,000 on April 1 last, to P68,000,000 at present; the subsidiary silver from twenty-two to thirty million pesos in the same period. The conditions of the foreign markets has prevented the merger of the National Railroad of Mexico and the Mexican Central Railway from being consummated, and though a decree was issued July 6, laying down the lines along which the new company is to be incorporated, it does not seem wise under present circumstances to go on as yet with the incorporation or with the financial operations to which it must give rise." (Since the reading of the President's message there have been rumors to the effect that the merger had fallen through; that controlling interests in the Mexican Central Railway had made conditions to which the Mexican Government would not comply.) Concluding, the President said: "The foregoing review proves to you that the efforts of the Executive to give added impetus to all branches of the public administration have not been barren, seeing that all of them show the progress which for some time past has reflected the growing prosperity of the Republic. Not even the transient stringency of foreign markets has been able to arrest our country's progressive movement, for though it has prevented the immediate realization of important combinations involving the railways of the Nation, it has not sufficed to curtail the yield of the public revenue, which has continued to expand, or to occasion any appreci-

errible contraction of the currency. It is to be hoped that this prosperous situation in Mexico will be maintained."

Toronto, Canada.

Progress at Cobalt.—New Machinery and Mills.—Sale of the La Rose.—Ore Shipments.—Discovery in Temagami.—New Trail to the Yukon.—The Dominion Coal Litigation.

The leading mines at Cobalt show great activity in development work and installations. The Nipissing has closed a contract with Cobalt Concentrators, Ltd., for the erection of a concentrating mill on their property, near the Kerr Lake spur of the railroad, now in course of construction. The work has been commenced. The present force employed numbers about 300, but will be largely increased shortly.—A new shaft and ore-house on the Kendall vein has been put up. The shaft has reached a depth of 90 ft., and drifts have been started at the 60-ft. level. The vein, which averages 5 in. wide, continues to look well. A new power-house is being erected for the installation of two 125-hp. boilers and a 17-drill compressor, for working the veins at the southwest end of this part of the area. Ore is now sampled and crushed on the ground previous to shipment.—The McKinley-Darragh is sinking a shaft on the extension of the Kendall vein. Their new concentrating plant is steadily in operation, treating 15 tons of ore per day. Another compressor of 15-drill capacity will shortly be installed.—The O'Brien is getting in one of the biggest plants in the camp, including two 100-hp. boilers, a 20-drill compressor, and a dynamo. The main shaft has reached a depth of 320 ft.; another shaft is down 85 ft., and a third 50 ft. Drifts and cross-ents have been made to the extent of 2,000 ft. An electric apparatus for tracing veins, operated by Williams, the inventor, has been in use all summer. At the Trethewey driving and cross-cutting at the 50-ft. and 100-ft. levels have been steadily carried on, about 1,500 ft. in all having been done. Four good veins carrying native silver have been found. It is reported that the La Rose mine has been sold for a high figure to English capitalists.—Shipments of ore from the Cobalt district for the week ending Sept. 21 amounted to 230 tons, from the following mines: Buffalo 30 tons, Coniagas 32, La Rose 63, Nipissing 73, and O'Brien 30 tons.

Considerable development work is going on in James township. Shipments are being prepared from the Gates claim and S. R. Cragg's location, where a smallite and silver vein 17 in. wide is being developed. A vein 8 in. wide rich in native silver has been found on the Downey property. A recent find on the Lucky Godfrey claim gives an assay of \$180 in silver per ton.—The Temiskaming & Northern Ontario Railway Commission has received a report from Arthur A. Cole, mining engineer to the Commission, indicating the opening up of an important new mineral area in the Temagami district. He reports having visited a mining claim five miles north of Temagami station and half a mile from the railroad, where the country rock is fractured Keewatin diabase, showing numerous quartz veins. In one of these, which was being worked for molybdenum, gold was accidentally discovered. The vein, two inches wide, was in one place rich with visible free gold. Copper was also found on another claim in the neighborhood, a fine specimen of which accompanied the report.

A large party of visiting English journalists has been touring through the mining areas of northern Ontario for ten days, accompanied by Mr. Frank Cochrane, Minister of Mines; they returned to Toronto on the 25th.

They were enthusiastic over the prospects of Ontario as a great mining country. The visitors were entertained at luncheon by Premier Whitney and the members of the Government.

Chihuahua, Mexico.

The Mines of the Santa Barbara District.—Tecolotes.—Montezuma Lead.—San Diego.—Hinds Consolidated.—Granadena.—San Francisco del Oro.—El Rayo.

The mines of the Santa Barbara district can, for convenience, be divided into four groups. In the town of Santa Barbara the principal mines are the Tecolotes y Anexas, owned by the American Smelters Securities Co.; the Montezuma Lead Co., owned by R. S. Towne and associates; the San Diego y Anexas, owned by the Torreon smelter interests; and the mines of the Hinds Consolidated Mining Co. In the Buena Vista district, which is about four miles north of Santa Barbara, are the Granadena, Merced, and Guadalupe mines owned by the Granadena Mining Co., the Igualdad mine, and others of smaller note. In the San Francisco del Oro district are the San Francisco del Oro mines, the Cuadras, Bronzes, and others of lesser note. At Los Azules, about 7 or 8 miles northwest of Santa Barbara, is the property of the El Rayo Mining & Development Co. With the exception of the last named all of these mines are working fissure-veins in limestone. The fissure-veins of the El Rayo mines are in trachyte.

The Tecolotes y Anexas mine is on a fissure-vein in the limestone, dipping west, and is 4 to 10 ft. wide. There are also two or three intersecting veins. The main vein is followed for a distance of about 2,000 ft., where it is sharply cut off by a large porphyry dike running in a general east and west direction. This main vein is opened up along its strike by four tunnels, and by a three-compartment shaft.

The ore is mined by overhand stoping, using Wah plug-drills. The miners stand on the broken ore, of which just enough is drawn out from the chutes at the main level to permit working room. The ore is drawn out of the mine in trains of 4 cars holding 5 tons each. These are hauled by an electric locomotive and dumped into a 1,000-ton bin. From the bin, the ore is hauled in trains of 5 cars of 6 tons capacity each by Shay locomotives.

The general milling scheme includes crushing with gyratory and Blake crushers and rolls to 6 mesh, followed by treatment on jigs, tables, and vanners. The middlings from the jigs and tables is crushed by rolls and Huntington mills, and re-treated on tables and vanners. The capacity of the mill is 450 tons per day.

A large 3,000-hp. gas generating-plant supplies power for the mill for compressing the air for the mine-drills, and for running the mine-locomotives and the electric hoisting engine at the shaft.

The Montezuma Lead Co. has a large property. At the present time very little is being done. When in operation, the ore was hoisted from three shafts and hauled to the mill, the capacity of which reached 300 tons daily. The general outline of milling was to crush with Blake crushers and rolls to 6 mesh followed by treatment on jigs, tables, and vanners. The jig middling was crushed and then sent to tables and vanners. A poor saving was made. A Wetherell electro-magnetic separator was installed for making a test on the zinc middling; this gave a fair extraction.

The San Diego Co. has shafts on several veins, one of which is at the mill, and from these shafts the ore is hoisted and hauled to the mill, which has a capacity of

60 to 75 tons per shift. The ore is crushed in Blake crushers and rolls to 6 mesh before treatment on jigs, tables, and vanners. The jig middling is re-crushed by rolls and re-treated on tables and vanners. The table middling is dried and run through an electro-magnetic separator to make a saleable product of the zinc-blende.

The principal mine of the Hinds Consolidated is the Clarines, which is developed to a depth of 220 ft. below the tunnel-level. Recently the Reforma mine has struck a body of sulphide ore of good grade and a drift is being pushed toward the Clarines, which is on the same vein. It is the intention to connect this drift with the fourth level of the Clarines.

The ore in the Clarines mine is mostly oxidized, containing lead, iron, copper, and zinc, and also some gold and silver.

A spur from the Mexican Central is being run to the Clarines to haul away the sorted ore and the concentrates to be made in the mill. Two 100-ton experimental mills are being built; in most respects they follow the general practice of the district.

The principal mine of the Granadefia Co. is the Granadefia itself, which is developed to a depth of 350 ft. The ore is a complex mixture of sulphides of lead, copper, iron, and zinc, carrying gold and silver. The average gold contents are higher than in any mine in the Santa Barbara district.

The Granadefia vein has a dip of about 70° west and has a general north-south strike. Its average width is three feet. Driving is done with machine-drills, and stoping by hand-work. The ore is removed both by overhand and underhand stoping and is hoisted to the surface through two shafts, where it is sorted and then hauled to the mill in mule-cars of about two tons capacity.

The milling practice is, in general, about the same as in the rest of the district, but the details are carried out in a more logical manner so that the efficiency of saving and commercial results are better than usual.

The ore is crushed in a Blake crusher and rolls to 12 mm. and treated on jigs, tables, and vanners. The jig middling is crushed twice through rolls and a Bryan mill and then re-treated on jigs, tables, vanners, and slime table, the object being to grade the crushing so as to reduce the quantity of slime to a minimum.

Water here is scarce, so an efficient settling system was designed. It was found that a zinc concentrate of 35 to 40% could be made by water concentration, which could be increased in grade and percentage of extraction by careful sizing of the 12 to 100 mesh material before treatment on the tables, vanners, and slime table. Eighty to 100 tons are treated per shift of 12 hours.

The San Francisco del Oro mines are probably the oldest in the district, being worked in the early days for the gold ore that was found at the surface. With increasing depth the ore turned to lead and zinc. An aerial tram was built to carry the ore to a point from which it could be conveniently loaded into wagons and hauled to San José, on the Parral & Durango railroad. At the present time a 50-ton experimental mill is being built; this is to employ Sutton-Steele tables and a flotation process.

The El Rayo mines are working on veins in trachyte, the ore from which is pyrite in quartz. About one-half of the gold is found in the pyrite. The ore is crushed to 60 mesh in a Blake crusher, rolls, and Huntington mills, and concentrated over vanners, where the pyrite with its gold content is recovered. The vanner tailing is classified, the sand being leached by cyanidation, and the slime agitated by mechanical stirrers with a cyanide solution. It is claimed that 90% extraction of the total gold in the ore is obtained.

Salt Lake, Utah.

Side-Line Agreement. — Shipments from Tintic. — Lucin District. — Consolidated Mercur Report. — Dividends in September. — Park City Mines Close Down. — Bingham Mining Affected by Copper Market. — A New Mill. — Railway to Pioche.

The ore shipments from the Tintic district last week amounted to 159 carloads, the contributing mines and respective amounts being: Ajax, 1; Beek Tunnel, 9; Bullion Beck, 4; Colorado, 10; Clift, 1; Centennial Eureka, 42; Carisa, 4; Depue, 1; Eagle & Blue Bell, 9; Eureka Hill, 5; Gemini, 5; Godiva, 2; Grand Central, 12; Lower Mammoth, 8; La Clede, 1; May Day, 10; Mammoth, 8; Scranton, 8; Shoebridge Bonanza, 1; Uncle Sam Con., 5; Victor Con., 1; Yankee Con., 5; Ridge & Valley, 2 carloads.

The Colorado, Crown Point, and Iron Blossom companies in the Tintic district have entered into an agreement to sink a joint shaft to be used in the development and operation of those mines. The boundaries between them are to be governed in the future by vertical lines. — The shaft of the Utah mine at Fish Springs has been re-timbered to the eighth or lowest level. This became necessary on account of the fire several months ago. — Much mining activity is reported from the Lucin copper district, in the western part of Box Elder county. The Copper Mountain mine, operated by the Salt Lake Copper Co., has 100 men employed and is shipping to the Salt Lake valley smelters. The property is controlled by the Lewisohn brothers of New York.

Dividends amounting to \$187,750 were paid by six Utah mining companies during September, the contributing properties and respective amounts being: Colorado, \$120,000; Lower Mammoth, \$14,750; Uncle Sam Consolidated, \$15,000; May Day, \$12,000; Grand Central, \$12,500; Daly West, \$108,000. The Silver King Coalition Mines Co. posted a quarterly dividend of \$187,500 and the Columbus Consolidated a quarterly dividend of 20 cents per share, or \$56,707 for payment in October. — The Daly West, Daly, and Ontario mines at Park City have been closed indefinitely on account of labor troubles. Because the management of the Daly West discharged a shift-boss who belonged to the miners' union and refused to reinstate him, a strike was called. About 500 men quit. While there has been no discrimination against union miners, the respective companies have employed non-union men as well, steadfastly refusing to recognize the miners' organization. — The Honerine mine at Stockton has been closed and the matter of resumption will come up for consideration at the annual meeting of shareholders on October 21.

The Bingham Consolidated Mining Co. has closed its Commercial mine indefinitely. The United States Mining Co. has ceased operations in the Old Telegraph mine and is only drawing on the galena mine for 125 tons of ore daily. These mines are productive of low-grade copper ores, which are not profitable to handle at the present time. The product can be handled advantageously, however, when absolutely needed as a flux for the silicious ore brought to the smelters from other districts. The Majestic Copper Co. has ceased production from its Old Hickory mine in Beaver county on account of the recent drop in the price of copper. The company has been shipping low-grade material to the Salt Lake smelters and derived a satisfactory profit when the market price of copper was above 20 cents per pound.

The New Stockton Mining Co., operating at Stockton, Tooele county, is installing new mill equipment, which will increase the capacity of the plant from 60 to 150 tons per day. The Stockton has shipped considerable high-grade lead ore during the present year, but the mine is

considered a low-grade proposition and will require a concentrating mill. The mine owners of the American Fork district are agitating the matter of better transportation facilities. An effort is being made to construct a railroad from American Fork to a point near the Wyoming mine in American Fork canyon. Fifty teams are engaged at the present time in hauling ore from the Wyoming property.

The Markham Gulch Milling Co. has completed a successful month's run on ore from the new Red Wing mine in Bingham. This property is opening up splendidly. Some important developments are looked for in the Utah Apex mine at Bingham. For some little time the management has been driving from the bottom of the 200-ft. winze from the Andy tunnel level, and the face is nearing the point where the orebody exposed in the upper workings should be encountered. Overhead the orebody showed a width of 12 to 15 ft. and shipments made from there have netted \$15 per ton. Utah Apex is producing copper at a cost of 6 to 8 cents per pound.

The citizens of Pioche, Nevada, are preparing to celebrate the arrival of the railroad in that camp. The Caliente & Pioche branch of the Salt Lake route is completed to a point within five miles of Pioche. It is expected that the road will be opened for traffic about November 1. The Western Pacific railroad will begin operating regular freight and passenger trains between Salt Lake City and Bews, Nevada, on October 1. The road will then be a competitor of the Harriman system on freight and passenger business to Ely and other points in eastern Nevada.

Denver, Colorado.

Cripple Creek Affairs.—The El Paso Case.—Western Federation.—Burns and His Antics.—Progress at Silverton.

Cripple Creek has been receiving a good deal of newspaper publicity lately. What with the disagreement within the directorate of the El Paso company, the revolt against the card system, the continuation of the Burns-Portland feud, and the discussion as to whether the Golden Cycle mill is to be rebuilt, the correspondents of the daily press have seldom been at a loss for material. The status of the El Paso case has been somewhat modified by the payment of the loan of \$15,000, which the El Paso company made to A. L. Burris some two years ago, and which seems to have been juggled with on the books of the company in a discouraging manner. Mr. Burris now flatly charges the president of the company with so manipulating its business affairs as to cause the stock quotations to fluctuate in a manner calculated to add to his personal gain, regardless of the interests of the stockholders, citing as examples the recent shut-down of company operations, and the delay in the work of driving the deep drainage adit, which he alleges was purposely caused to depress the stock to a figure at which the president could profitably buy back the shares he had previously disposed of at the top of the market. How nearly these charges are correct does not yet appear, but the general belief is that where there is so much smoke there must be some fire, and certainly the quotations of El Paso stock have been decidedly fluctuating. The card system disturbance seems to be the result of the virtual abandonment of that system in the San Juan, as a result of the serious labor shortage there, but which the Federation seems to think is due to its gain in influence. But Cripple Creek has an ample labor supply for the present, and the efforts of the Federation officials have so far met with a conspicuous lack of success. Feeling against the Federation is still far too strong in Cripple Creek for it to expect a recrudescence of

power there for a long time to come. In the Burns-Portland affair, Mr. Burns, disappointed in his efforts to secure a personal examination of the books of the company, has brought suit against the officials for \$1,000,000 damages, which he declares he has sustained by having the management of the company taken from him. This adds another specimen to the large and interesting collection of law-suits with which Mr. Burns whiles away his idle hours, finding that buying picture galleries, building libraries, or endowing colleges is far too tame an amusement for his strenuous nature. Probably his next suit will be for a billion dollars damages for the distress of mind to which he was subjected in being ousted from the control of the Portland, and thrust into outer darkness.

The Golden Cycle is at present treating the tailing dump of the old Telluride company in that portion of its mill that was not destroyed by the recent fire. The management continues to declare that the mill will be immediately rebuilt and that it is making contracts for ore at even lower treatment ratio than before, but the

Map of Southwestern Colorado.

speed at which reconstruction work is actually going forward seems hardly consistent with this, nor is the dismissal of a portion of the superintending and office force particularly reassuring. The other mills continue to work at full capacity.

One of the most flourishing parts of the San Juan is that tributary to Silverton, including Animas Forks and Gladstone. Numerous large mines and mills are in steady operation and the output has been strong throughout the summer, while development work has been correspondingly active. It is announced that the San Juan Smelting & Refining Co. will erect a 300-ton mill on Cement creek, just below Gladstone, near the Gold King and Mogul mills. The ore for the mill is to come from the Henrietta properties, and the production of that group should be considerably stimulated by the increased facilities. The Silverton district, like several others in Colorado, is somewhat burdened by the misguided zeal of optimistic individuals who proceed to drive adits thousands of feet into the face of nature, fatuously hoping to discover Golcondas and to eliminate the drainage problem from their plan of operations; but in spite of these, Silverton is 'making good.' The Ross smelter has shut down for the present, the low price of copper proving too much for a plant that has to rely on a purely local supply of ore. The properties owned by the Ross company have also been shut down temporarily, but the

custom ores, of which the smelter treated a steady tonnage, will simply be diverted to the Durango plant of the A. S. & R. company.

The Ohio & Colorado Smelting Co. has recently bought the control of a group of properties at Leadville, giving it a supply of ore that is more assured than a custom supply. One of the most conspicuous fakes in the State has also begun to operate in the Leadville district, and is proceeding to advertise its several million shares at a fraction of their par value, with the confident prediction that they will go to par by the end of the year.

Johannesburg, Transvaal.

The Guggenheims and Robinson. — Botha and the Cullinan Diamond. — The Work of Parliament. — Ignorance of Legislators. — Commissions of Inquiry. — The Problem of the Unemployed.

Much interest was excited by a newspaper report last week, that J. B. Robinson had induced the Guggenheims to put up £1,000,000 to open up some of his mines at Randfontein. Things must be rather bad in America if this report be true. A cautious man would think twice before he invested such a large sum on the Rand at the present time. The past record of the Randfontein district is not calculated to enthrall the would-be investor. So uncertain is the future, especially as regards labor, that American capital should be very careful in coming to the Rand. There are many safer outlets for any excess capital in the United States than the Randfontein mines.

The first parliament of the Transvaal is now over. The session closed at Pretoria last week. The last days were rendered very lively by the discussion on the proposal made by Premier Botha to donate the celebrated Cullinan diamond to King Edward, as a diadem in his crown from the people of the Transvaal. The Opposition were placed in an awkward position. Never before has there been so much distress in the country as exists today. To levy more taxation on the people at the present time to pay for a present to the King, is inopportune to say the least. Sir George Farrar, the leader of the Opposition, objected to the proposal in a dignified speech, declaring that His Majesty would rather see a prosperous colony than receive the greatest diamond in the world. The Government was obdurate, however, and the proposal to present the Cullinan diamond to King Edward was carried by a large majority.

A great amount of work has been rushed through Parliament this session. In reviewing the work one is forced to admit that the policy of the Government seems to be to use the mines for the benefit of the agricultural interests. The attitude of the Government has not been sympathetic to the mines, and if they continue as they have commenced, they will succeed in "killing the goose that lays the golden egg." Probably ignorance is responsible for most of the mistakes of the Government. There is not a single business or technical man in the ministry. They are farmers and lawyers. Their acquaintance with the mining industry is not much better than the man in the street, who has the extraordinary notion that the mining industry can carry any load that is thrust upon it. The ministry does not seem to realize that mining is a business, which can be killed by unsympathetic legislation, just as any other enterprise can be ruined.

Apparently the Government wants to run the country by commissions. These commissions are somewhat of a farce, and appear to be a waste of time. A commission appointed to report on the question of a patent law for the Transvaal handed in its report a short time ago. The Government paid not the slightest attention to the re-

commendations of the commission, and fixed up the patent law to suit itself, despite the protests of all the technical societies of the Rand. There is another commission sitting in Johannesburg now, the Mining Industry Commission, christened in derision the 'Creswell Commission.' Mr. Creswell was formerly manager of the Village Main Reef mine; he it was that advocated the use of more white labor on the mines. He proved to everyone's satisfaction, save his own, the impossibility of his scheme. Now that he has the power, he is 'rubbing it in' to the present management of the mine, demanding data which do not concern the commission at all. The inquiry seems to have degenerated into an attempt on the part of Mr. Creswell to prove his position. The only hope is that if he is given sufficient rope he will hang himself, for the more figures that are published, the more will it be shown how much superior the present scheme of running the mine is to his method. And Mr. Creswell appears to be

Transvaal and Surrounding Country.

the chief technical advisor to the Government. This explains a lot!

The thousands of unemployed men and women are clamoring to be repatriated, as there is no work for them to do, and they must live on charity or starve. Last week the Premier wrote to one of the Unemployed Committee stating that it will be unnecessary for any white man to leave this country, and saying that every effort must be made to increase the white population rather than diminish it. It is to be hoped that the Government can do something for the unemployed, but the outlook is not bright.

Your correspondent has been in this country nearly twelve years, but he never remembers seeing such a state of affairs as is witnessed in Johannesburg today. Go down any of the streets, and a man will come up and say, "Excuse me, Sir, but don't you remember we worked on the same mine some years ago? Well, I've been trying to get work for weeks past, and have not succeeded. I'm down to my last shilling, and would like you to help me!" You give the money with a heavy heart, not that you mind parting with a pound or two, but with deep regret that in this new country white men should find it necessary to beg in the public streets.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

POROUS SANDSTONES afford channels for water, and many tiny cavities that may be filled with precipitated minerals; hence they are often selected for ore-deposition in preference to adjoining strata.

SULPHATE ROASTING evolves a large amount of heat, and should easily proceed automatically, without extra fuel, if the physical conditions favoring the sulphate roasting are properly understood.

THE wetted perimeter of the cross-section of a channel is that part of its boundary that is in contact with the water. The hydraulic radius of a water cross-section is its area divided by its wetted perimeter.

IN hydraulics, the terms energy and head are often used as equivalent, although as a matter of fact energy is proportional to head, and lost head is not a loss of pressure-head alone, but also of velocity-head.

WATER is more compressible than iron, or than timber within the elastic limit. The amount of compression is directly proportional to the applied pressure, and water is perfectly elastic, recovering its original form on the removal of pressure.

A WATER-TURBINE is a wheel in which the water enters around the entire circumference, instead of at one point, so that all the moving vanes are simultaneously acted upon by the dynamic pressure of the water, as it changes its direction and velocity.

ASPHALTUM is reported as occurring at several places in the island of Cuba, and exploitation of the material has expanded greatly during recent years. The reports indicate that more than three-fourths of the asphaltum exported from Cuba is sent to the United States.

SAFETY LAMPS are designed to give light in gaseous workings without the danger of igniting the gases present. The principle of the lamp depends on the cooling effect that an iron wire gauze exerts on the flame, decreasing the heat below the ignition temperature.

TYPE-METAL consists of lead, tin, and antimony, or of only lead and antimony, but may contain a little copper or nickel. The antimony generally varies from 17 to 20%. Britannia-metal and white-metal consist principally of antimony and tin, with some lead, copper, zinc, bismuth, and nickel.

ONE of the first attempts at gold dredging in California was made in July, 1894, on the American river at Natoma. It was a grab dredger run by steam power and had a capacity of 500 tons per 24 hours, with two 10-in. pumps. The scow was 18 ft. wide and 30 ft. long. Three men were employed.

JOINTS are planes of fracture running through rocks, few rocks being without them. Fragments of broken rocks are often more or less completely bounded by plane surfaces, whether the rock is stratified or igneous. In stratified rocks, one or two of these plane surfaces are apt to be due to the bedding; the others are joints. In igneous rocks, all the planes are usually joints.

A RIVER VALLEY often shows along its sides shelves, terraces, or benches, part of the old river bottom when

the stream was at a higher level, before it cut for itself a newer and deeper channel. If the rock in the region is gold-bearing, and if there is gold on the bars and in the valley gravels of the present streams, then gold may be looked for in the gravels lying in these higher benches.

THE gypsum that is imported into the United States comes, except a few hundred tons annually from France and the United Kingdom, almost wholly from Nova Scotia and New Brunswick, and enters the ports of the New England and northern Atlantic States, over one-half entering the port of New York. The gypsum imported is nearly all calcined and converted into wall plaster. A small quantity is used as land plaster, and some is mixed in patent fertilizers.

THOUGH the facts that diamond-drills have a tendency to deviate from the vertical has long been well known to Rand engineers, the custom of surveying bore-holes did not arise till a few years ago. The result of the surveys has been to show that the deviation may be most serious, and the results obtained have to be viewed in a new light, not only in reference to the position of the reef where intersected, but also in regard to the width of the reef as shown by the core.

NEARLY all the refining of metals is based upon the fact that some, or all, of the accompanying impurities oxidize more readily than the metal which is under treatment. These oxides, being lighter than the metal, rise to the surface if they are not soluble in the metal itself, and may be skimmed off as a slag. This refinery slag also often contains a large amount of the oxide of the metal itself, and must be smelted again to recover this valuable metal.

IN copper smelting, it is not desired to obtain metallic iron, but to utilize the iron contents of the ore to form ferrous oxide, which will combine with the silica and produce an easily melted slag. Thus the furnaces are comparatively low, use a small proportion of coke, and the charge is so proportioned as to fuse at a moderate heat and form a readily fusible slag that will run out rapidly, the column of ore sinking through the smelting zone before the temperature is high enough, or the reducing action of the gases powerful enough to convert the iron oxides into metallic iron.

THE principal deposits of bauxite in the United States have been found in Georgia, Alabama, and Arkansas. During 1906 bauxite was discovered in Tennessee, Virginia, and Pennsylvania, far north of the deposits previously known. It is noteworthy, however, that although these new discoveries extend the area known to contain bauxite, the general location, relations, and character of the deposits fulfill the conditions described by Survey geologists a decade ago—that is, the bauxite is invariably associated with Cambrian or Cambro-Ordovician rocks, such as Knox or Shenandoah limestone of the valley regions, and in association with faults.

WHEN applied to materials used in the construction of furnaces, fusibility is a comparative term. In fire-brick there are various degrees of fusibility, and in certain portions of a reverberatory furnace, such as the arch, bridge, and side-walls, the most infusible fire-brick that can be secured is none too refractory. For such places, the silica, or dinas brick is employed. This consists principally of silica, mixed with just enough refractory binding material to hold the grains together. As the joints are the weak spot in the brickwork, the mortar for silica brick should be made of the same materials as the brick itself.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Plumbing a Deep Shaft.

The Editor:

Sir—In your issue of August 25, 1906, there is a brief but very clear and interesting article by Mr. W. E. Downs on a quick method for a vertical shaft survey. The method described has features that commend it in cases where hurry work has to be done and in others where the degree of precision required is not too high. Should there occur an opportunity to check the azimuths in the survey described by means of a plumb-line in another shaft, other engineers will without doubt be glad to learn what degree of precision was attained. It will, of course, be quickly recognized that with so short a base line as 2.43 ft. slight changes in relative position of the wires mean relatively large variations in azimuth. Probably most engineers will agree that had it been possible to hang the wires further apart and set the transit up well outside their plane more accurate results might be expected with little, if any, sacrifice of speed in performing the observational work, since the process of 'jiggling in' would have thus been avoided.

The soft drawn wire has some obvious advantages as pointed out, but it may be questioned whether a No. 24 piano wire with 60-lb. bobs such as I have seen used is not sufficiently superior to the No. 12, B. & S., soft iron wire with 125-lb. bobs to compensate for the somewhat greater care necessary in reeling to avoid troublesome kinks.

The offhand explanation of the downward divergence of the wires as due to gravity and entirely independent of falling water and air circulation must be taken with considerable caution. In this connection it seems remarkable that there exists even among engineers and other trained persons such a general lack of appreciation of the forces of gravitation except in the single instance of the forces between the earth and objects upon it. It is true that the bobs are separated somewhat by gravitation, as Mr. Downs states, but the amount of such deflection is greatly over-estimated. Dimensions, which are not given, would be needed to compute it, but judging from results obtained in my investigation at the Tamarack mine*, it is scarcely possible that it exceeded one two-thousandth of a foot, that is, one fortieth of the divergence observed. Probably it was much less than this.

A much more likely cause of the divergence might be found in the magnetic conditions about the wires. No account of these is given, but it is easy to imagine the presence of a large air-pipe and possibly steam-pipes. Each length of these is a strong magnet with north pole at the lower end. Where lengths are joined, especially if it is by means of flanged junction, such pipes create a strong horizontal field, and, since the effect of such a magnet is roughly inversely as the square of the distance, it is not difficult to see how it might produce both divergence and, what is worse, deflection affecting the azimuth. Further, any horizontal polarity might be disposed so as to add its effect, though with torsional vibration the effect could not be constant, while longitudinal polarity in the bobs, if in the same sense in each bob as it might quite easily be, could alone produce all the observed divergence. There is also a very small repulsive force between the extremities of the wires themselves independent of their surrounding and due to the fact that, like

the pipes, they are in the earth's magnetic field and are magnetized with lower extremities as north poles. The amount of this force is too small to be significant in the case described.

The statement that "drafts and falling water do not have any effect on the sum total of this divergence," depends for its accuracy altogether on the local conditions. With a shaft as deep as a thousand feet and with openings of a considerable size tributary thereto, it is more than likely that air currents may be responsible for divergence, convergence, or abnormal azimuth. That the diverted position of one or both wires may be of remarkable steadiness was convincingly shown in the observations on the long lines in the Tamarack shafts above referred to. Water, also, if entering more from one side than the other, might have a total effect in some horizontal direction. Indeed, it might be fairly questioned whether in a 2,000-ft. shaft with a good deal of water the easterly deviation of a falling body might not appear as a factor in the deflection of a plumb-line from its normal position. Whatever may affect the position of the wires, it is obviously only the difference of the effect on the two which appears in convergence, divergence, or changed azimuth.

The engineer confronted with the problem of plumbing a deep shaft has considerable difficulties to overcome if it is necessary to do precise work, and he should study very carefully the surroundings with reference to the magnetic conditions, the circulation of air and the falling of water in order to decide on what is the best procedure to follow, and to judge correctly the precision of his results.

Speculation or Investment?

The Editor:

Sir—I note with considerable interest an article in your paper of the 21st inst., under the head of editorial, regarding the removal of two dredges from Colorado to California. The article ends with the statement that "mining is, was, and will be to the end of time a sane speculation or a silly gamble, but never an 'investment.' The element of risk is never eliminated, and any statement to that effect, as regards a particular mine, is made by the charlatan or the fool." Don't you think this is a rather broad statement, and why should mining be eliminated from the category of judicious investment? Take for an example a carefully developed mine, with a certain tonnage absolutely blocked out, and in sight. Carefully conducted milling, and money in hand as result of same, show the value of the ore to be such as place it far beyond the danger line. Is this in your opinion a speculation, or what side of the fence are you on?

An engineer might carry enough up his sleeve to eliminate any risk, and still call it an investment. How about the Independence? I can understand your statement coming from an investor, but hardly from an engineer, or the editor of a mining paper.

F. E. WILLSON.

Boise, Idaho, September 25.

[Mr. Willson's objection is reasonable. Like most discussions, this one ought to have been prefaced by a few definitions. Mr. Willson and the Editor are probably in agreement as to their ideas, but not in regard to the terms employed. An 'investment' differs from a 'speculation' in that the element of risk is eliminated, thus United States bonds and British consols are typical investments, so are the bonds of railroad companies that are well managed and have weathered the financial

* See *Electrical World* for April 26, 1902.

crises of times of depression, such as the Pennsylvania, New York Central, and the like. The test of an investment is easily made. If you are willing to lock it up in a safe for, say, five years, it means that the fluctuation in the principal is subordinate to the interest receivable and that you are holding it merely as a source of income. In the case of a mining share the question of interest is quite subordinated to that of an enhancement in the principal; you would be unwilling to lock up your stock in a safe for any length of time, knowing that it is liable to fluctuations so great as to make its income-bearing feature unimportant as compared to differences in the quotation. A mine may double in value within a week; an established railroad is not subject to violent fluctuation in capital worth and even the changes that do occur are not likely to affect the earning power of the bonds, the interest on which is fixed at a maximum, while in the case of a mine the dividends obtainable are unlimited. For this reason most people prefer mining stock paying 10, 15, or 20% to a bond paying 3½ to 4%. Despite the risk, the greater returns make the mine share more attractive than the railroad bond. Of course, railroad shares are speculative; owing to the games of big gamblers such shares are just as risky as mining stocks, without the possibilities that make mining so attractive. Replying to Mr. Willson; even a well developed mine, with ore in sight, a good mill, etc., is not an investment, but it is an excellent speculation. A fire in the mine or mill, litigation, labor strikes, dishonest management, an error in the estimates, a refractory change in the ore, increased cost of operation due to water, and so forth, are among the dangers to which the best mine is subject. On which side of the fence are we? On the side of fact. As to the Independence, that was a good speculation, which was made a poor gamble by absurd mismanagement of its affairs. The editor of a mining paper is in control of a publication devoted to the application of science to industry; in consequence, he has to deal with facts, incidentally combating popular error and make-believe—and all in the best interest of mining. To regard mines as good speculations instead of fixed investments will not hurt business; to get alongside of facts will promote honesty.—Editor.]

Searching Questions.

The Editor:

Sir—It often happens that young engineers are called upon to make an examination of mining properties before they have had any experience in work of this kind. Of course, there must be a first time for every engineer. Assuming that he is competent to make the examination and deliver the report, there are a good many minor questions regarding the etiquette of the transaction, the answers to which are not in the books; the only standard the young man has by which to gauge his procedure, is what the seasoned engineers can tell him, and the scattered and scanty information on this subject that is in print. Therefore, in behalf of the younger generation, I would like to ask the following questions, all of which are simple, many of which may seem unimportant, but most of which are of interest to the man who has had but little experience in examination work. If we could get answers to some of the questions from several men, we might deduce a series of useful rules. The objection will probably be raised that the questions are too ambiguous to be answered intelligently, as each individual case introduces diversified conditions. But it is impossible to arrange a more detailed set of questions in a compact form, so they must be treated in a general way. Assuming that the examination will consume from one to three

months, and entails the necessity of a rather long journey on land and water, the man for instance starting from Colorado, bound for the tropics, and that the amount involved is about \$100,000, then;

1. Is it better to charge a fee, or undertake the work on a salary basis?

2. Is it advisable to have a written contract with your employers, properly drawn up and signed, or is the letter or telegram engaging you for the job sufficient?

3. Can a lump sum be demanded in advance to cover all the expenses of the trip?

4. Can the company properly be charged with all of the equipment necessary for the work, outside of the personal necessities of the engineer?

5. About traveling expenses. (a) Are tips to servants, laundry bills, tobacco, ammunition, medicines, etc., legitimate expense items? (b) Is the engineer entitled to the best first-class passage on train and on shipboard, and to the best accommodations at hotels? (c) If the young man be of an economical turn of mind, is it right for him to travel second-class, or even steerage, and charge the company first-class, he pocketing the difference? (d) How minutely must the details of the expense account be kept? Are frequent charges of 'incidentals,' to cover small expenses, permissible? (e) Is it best to take vouchers for large expenditures? If so, over what amounts? (f) Can expenses incurred in entertaining men while getting pertinent information from them, be entered on the account? (g) If the expedition consumes say three months, should the statement of expenses and cash balance be rendered weekly, monthly, or at the end of the engagement?

6. If you are sure of your fee, is it a good plan to send periodical reports on the progress of your investigation, giving results, such as assays, as they are obtained in the course of the work, or is it better to withhold all this information until your final report? Is the company justified in demanding frequent periodical reports of this kind?

7. If your examination indicates to you that the shares should be worth more than they are selling for on the open market, is it fair to buy these shares, before your report is turned in? Is it all right to do so afterward? In other words, is it permissible to use information gained at company expense, for private gain, during or subsequent to your term of employment?

8. Is it legitimate to take advantage of your presence in a district, to examine, and perhaps option mining properties for yourself, provided your employers are not in the field to purchase new ground, and no time is lost that properly belongs to the company?

9. Should there be any objection to publishing, in technical periodicals, a description of the district visited, giving general information of the conditions obtaining there, the topographical and geological features, and conclusions concerning the possibilities of successful mining, provided, of course, your employers will suffer no direct injury thereby?

10. Is it always expected of the engineer to say 'yes' or 'no' to the property? Even though the property is comparatively undeveloped, or badly opened, and the facts obtainable are insufficient for an intelligent opinion, must the engineer always reach a definite conclusion? If the mine is an old one, badly caved, is the engineer justified in spending company money to clear out old drifts, unwater shafts, and open caved ground, and may this work be properly charged in his expense account, without definite authority for such work from his employers?

San Francisco, September 18.

A Handy Windlass.

Written for the MINING AND SCIENTIFIC PRESS
By F. S. BECKETT.

The accompanying drawing is of a windlass rigged up by the writer at the West Goldyke mine, at Goldyke, in Nevada. With the help of this windlass, a 100-ft. shaft has been sunk and a 290-ft. cross-cut run quickly and economically. About 180 lb. of rock is raised on each

A Handy Windlass.

trip, besides the weight of bucket and rope, but by employing a counterbalance and a self-dumping arrangement, one man does the windlassing with no more effort than two men usually put forth with the ordinary arrangement.

The counterbalance is weighted so that it requires nearly as much effort to raise it and lower the empty bucket as to raise the full bucket and lower the counter-

balance. That portion of the drum where the counterbalance rope binds is smaller than where the bucket rope winds. The counterbalance thus moves slower than the bucket, and never reaches the bottom of the shaft, to be in the way of those working there. This portion of the drum is also tapered so that as the counterbalance falls and the unwinding rope adds to the suspended weight, the radius of the drum decreases. Thus the pull on the handle of the windlass due to the counterbalance remains uniform, being independent of the position of the weight hanging in the shaft.

In dumping the bucket, the windlass man's hands do not leave the handle. The operation is as follows: As the bucket approaches the collar of the shaft, the bar on the bottom of the bucket strikes the V-shaped deflector, and the bucket is turned so that the two ends of the bar slide along the two vertical guides until they fall into place on top of the guides ready for the bucket to be dumped. The bucket now tips slightly forward, being pulled into that position by the rope. When the motion of the handle is reversed, it gradually tips and dumps the rock in the chute and ear. Should a heavy piece on one side of the bucket overcome the tendency to tip forward and compel it to tip backward, the handle is reversed until the bucket leans against the 2 by 6-in. guard, when a smart forward turn throws it forward with sufficient force to overcome the tendency to tip backward. After the load is dumped, the handle is turned forward, and just before the bucket reaches a vertical position another extra push on the handle throws the bar off the top of the guides, freeing the bucket for its trip downward.

The shaft is cribbed as shown with 2 by 12-in. plank, with a 1 by 2-in. partition, which has proved heavy enough for the ground. About one-half of the manway is carried up 12 ft., and on top of this a simple wind-sail is placed. With this arrangement the ventilation has always been good, and even at the breast of the cross-cut a lighted candle shows considerable movement of air.

Anyone who can handle rough carpenter tools can easily put up such a windlass, and timber the shaft, out of 1 by 12-in. and 2 by 12-in. board. The sheave can also be home-made in the form of a wooden roller.

IRON ORE FROM THE LAKE SUPERIOR REGION.—The greater portion of the iron ore mined in the United States is obtained from the territory tributary to Lake Superior, and thence taking its name of Lake Superior region, which has produced an enormous amount of iron ore. The bulk of this ore is forwarded from shipping ports on Lake Superior and Lake Michigan by vessel to the docks at the lower lake ports on Lake Erie, from which it is sent by rail to blast-furnaces in Pennsylvania, Ohio, West Virginia, Virginia, etc.—in one case of temporary need being transported as far as Colorado—and to receiving ports at Chicago, Milwaukee, etc. There are five shipping ports on Lake Superior: Duluth and Two Harbors in Minnesota; Superior and Ashland in Wisconsin; and Marquette in Michigan; while two ports, Escanaba and Gladstone, are on Lake Michigan, both being in the State of Michigan. Duluth, Minn., generally leads as a shipping port, followed by Two Harbors, Escanaba, Superior, Ashland, and Marquette. The iron ore obtained from the Mesabi and Vermilion ranges in Minnesota is shipped by way of Two Harbors, Duluth, and Superior. From the Gogebie range in Michigan and Wisconsin the ore goes to Ashland; from the Marquette range in Michigan by way of Marquette and Escanaba; and the Menominee range ores from Michigan and Wisconsin are shipped from Escanaba, some of the Gogebie ore also reaching the latter port.

finer particles, being ordinarily caught quite as much on the plates as in the mortar when milling with a 20-mesh screen. In rich shoots, however, large nuggets are said to have occurred. The ore from this vein is easily distinguished by the angular appearance of the included slate. The 'belt' is hard, with quartz stringers through it. The main body of the quartz adheres firmly to the hanging and may be taken down by itself after the slate has been stoped.

Fig. 3 shows the Nigger vein, looking east at a depth of about 60 ft. This vein lies 360 ft. north of the Leary, and, according to Mr. Faribault's map, is at this point only 65 ft. south of the anticlinal axis. The dip is about 58° . The belt of slate and quartz is about the same width as the Leary, but is softer, and the quartz and slate come down together. The best ore occurs in the 'rolls' in the vein, one of which is shown in the photograph. The next one is about 12 ft. above this. They

in this, from 8 to 12 in. wide, above which is 12 to 16 in. of quartz with included slate, partly covered in the photograph by the man's arm. Above this is another narrow slate band on the hanging. The width of the whole 'belt' between the 'whin' walls is six feet. The gold occurs here both in the comparatively clean quartz, and in that above, containing slate. It is so coarse that, in a mill-run where 87 tons crushed through 20 mesh showed 80 oz. of gold, 97% failed to pass the screen and was cleaned up from the mortars. During the period of ore deposition some of the pieces of gold had ample room to choose their own form, for crystals are common, one noticed being over a fourth of an inch across. Another piece of ore shows an eighth-inch gold wire in the midst of an inch mass of pyrrhotite, with plates of gold in the white quartz near by. On the pyrrhotite is a coating of chalcopyrite.

The development on this vein showed a feature not

Fig. 3. A Roll in the Nigger Vein.

Fig. 4. Face of Nugget Vein on 240-Ft. Level.

have a slight downward trend, possibly 15° , toward the west. The quartz varies from 24 in. wide at the rolls to 10 in. between them. It differs from that at the Leary in that the slate is not often included in angular shapes, but occurs so as to give the vein a banded appearance. This photograph is especially interesting because of the wedge-shaped quartz and included slate at the 'roll,' as if the quartz had actually been bent when in a plastic condition, and the cracks, diverging from the centre, had been filled with slate, after which the whole was cemented with more silica. Nuggets weighing up to one ounce are of frequent occurrence in this roll while they are rare in the narrow portion of the vein.

Fig. 4 shows the face of the 240-ft. level looking east on the Nugget vein. This vein lies 95 ft. north of the Nigger, but as this shaft is about 1,100 ft. east of the work on the Leary and Nigger already referred to, and the veins diverge from the anticlinal axis in going east, the Nugget vein is at this point about 80 ft. south of the dome of the anticline, according to the map of Mr. Faribault. The dip of the vein is about 60° south. As indicated in the photograph, the ore is quite different in appearance from that in the Leary and Nigger. The vein, which in the inaccessible level 90 ft. above is said to have been 22 in. wide, has here widened to five feet, the larger portion being white quartz. There is one band of slate

observed on any of the other veins accessible. In following the slate and quartz from the surface the quartz entirely disappeared at a depth of 127 ft., and from this point, excepting for a few stringers, the belt appears as an ordinary stratum of slate. However, the pay-shoot was encountered at the point expected, about 17 ft. east of the shaft on the 240-ft. level, and has continued for over 100 ft. toward the east. The pay-shoots on this vein are supposed to trend westerly at an angle of about 45° , but this is not proved.

Why veins so close together, and formed simultaneously, should exhibit such varying characteristics, is a problem for the geologist. It should be said that Mr. Faribault considers the "dome of the anticline," from which there is a slight dip both easterly and westerly in addition to the steep dip northerly and southerly, to be situated at a point about north of the shaft on the Kent. It may be that this condition had some influence on the vein formation, resulting in the frequent small swells in the more distant Leary, the more pronounced 'rolls' of the nearer Nigger, and the broad shoot of the Nugget close to the dome. It would seem, with the multitude of shafts on this property, that there should be some record as to the occurrence of rolls on veins in the vicinity of the Nigger, or of wide shoots on veins near the Nugget.

Re-timbering the Kearsarge Shaft.

Written for the MINING AND SCIENTIFIC PRESS
By LEE FRASER.

As a result of the fire during the month of September, 1906, in No. 1 shaft of the North Kearsarge branch of the Osceola Consolidated Co. at Calumet, Michigan, it has been necessary to re-timber the shaft and to remove a large quantity of loose rock, which had fallen from the hanging wall after the supporting timbers were burned away. The shaft, approximately 3,800 ft. deep, lies in a vein dipping at an angle of 42 degrees.

When No. 2 shaft was bottomed on the 24th level, work was discontinued, and subsequently sinking was begun on No. 1 shaft, 400 ft. to the southwest. Between the 11th and 15th levels the shaft was put down through the stopes and drifts that had been worked from No. 2 shaft before it was abandoned. The ground had been stoped to such an extent that in many places little of the vein remains for a shaft-pillar. The seat of the fire lay in the vicinity of the 15th and 17th levels, and as the shaft is an up-cast no damage from fire resulted below the point of origin. Some damage was done, however, by falling debris, but the great rush of rock was stopped by a jam in the shaft before reaching the 20th level.

ally falling from the hanging wall in large pieces, making it necessary to use every precaution against fatal accidents to the timbermen; both walls were unstable, and no foothold could be obtained for the timbers; the hanging wall was so high that it was impossible to support it with single stulls and impracticable to use spliced stulls.

Cross-Section of Shaft.

Running diagonally across the shaft in the vicinity of the 12th level are heavy seams of calcite and laumontite, and under the action of the intense heat of the burning timbers the rock broke away from the hanging wall along the line of these seams to such an extent that in places the distance between the foot and hanging measures as much as 50 ft. The hanging slopes away to its

Minor difficulties entered into the solution of the problem so as to make it appear almost impossible.

Above the cave, where the height of the shaft is normal (15 ft.) heavy stull-pieces were firmly wedged between foot and hanging and four 12 by 12 in. timbers were set together between the two skip-roads. A substantial temporary foundation was thus formed from

Details of Cable Attachment.

maximum height in a distance of about 200 ft., while on the south side of the shaft for almost the entire distance between the 11th and 15th levels open stopes extend into the vein for a distance of 100 ft. The north side of the shaft, however, is sustained by pillars.

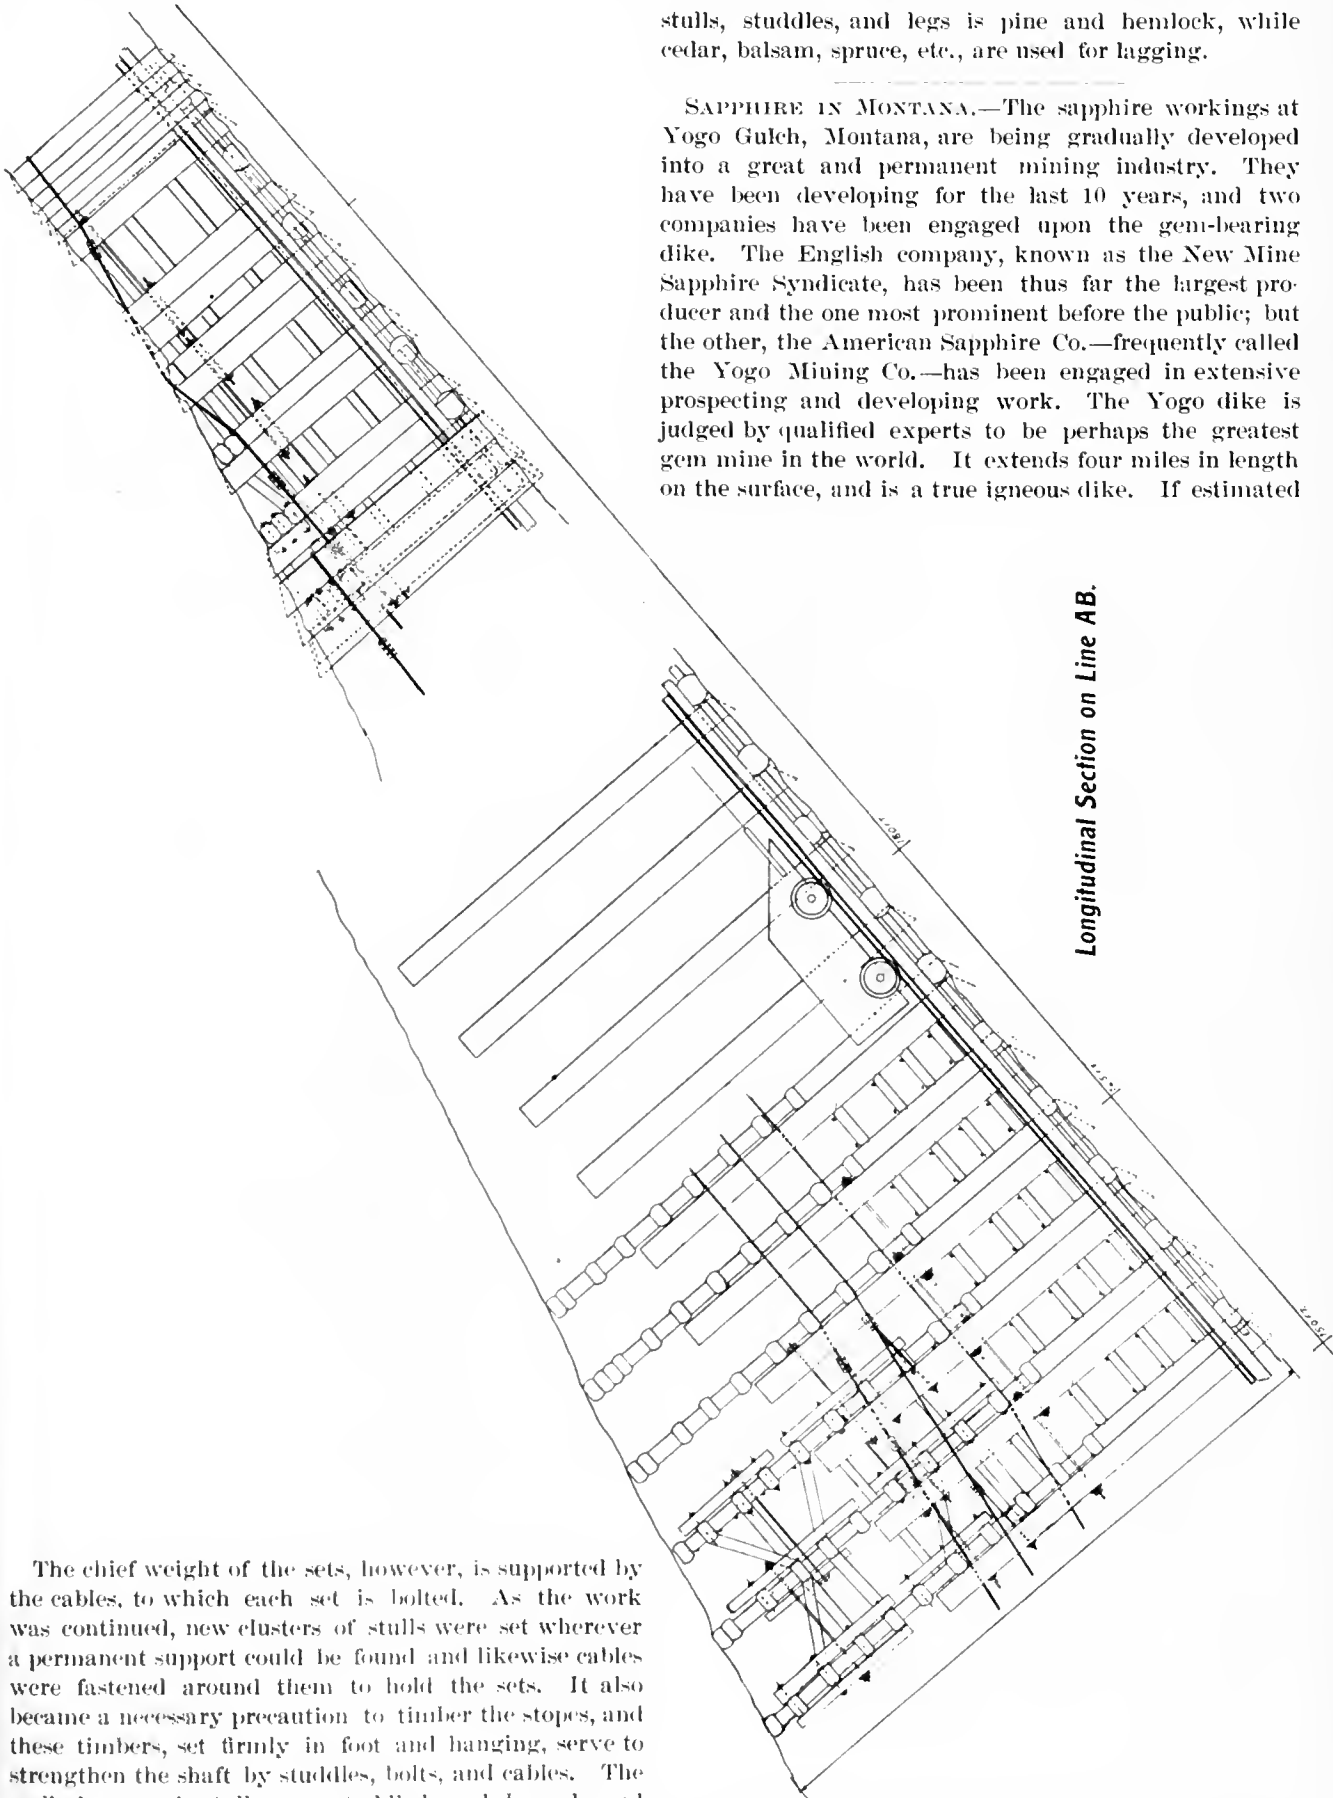

The dangers and difficulties in re-timbering the shaft were many: It was choked with loose dirt; there were half-burned timbers and masses of rock 20 to 30 ft. long and from 10 to 20 ft. thick; loose rock was continu-

ously falling from the hanging wall in large pieces, making it necessary to use every precaution against fatal accidents to the timbermen; both walls were unstable, and no foothold could be obtained for the timbers; the hanging wall was so high that it was impossible to support it with single stulls and impracticable to use spliced stulls. Above the cave, where the height of the shaft is normal (15 ft.) heavy stull-pieces were firmly wedged between foot and hanging and four 12 by 12 in. timbers were set together between the two skip-roads. A substantial temporary foundation was thus formed from which to hang the remaining sets until the hanging wall is found of a normal height at a distance of from 300 to 400 ft. below, where the permanent foundation for the superstructure will be set. Heavy 1½-in. steel cable is fastened about the central cluster of timbers, while the loose ends are carried down the shaft, each set being hung from the preceding set by stay-bolts. The wall-plates are supported by leg-pieces, cut to bring the cap about 15 ft. above the foot-wall. The legs are firmly

wedged into the foot-wall and spiked to the stulls. Short studdles are then set on the caps, supporting in turn another wall-plate, until the set has been built up to the required height.

skip-roads to support the centre of the wall-plates. This will relieve the strain on the cables, for as the cables gradually stretch and give the weight will be delivered to the studdles, making the structure strong and permanent. The timber used in the construction for the stulls, studdles, and legs is pine and hemlock, while cedar, balsam, spruce, etc., are used for lagging.

SAPPHIRE IN MONTANA.—The sapphire workings at Yogo Gulch, Montana, are being gradually developed into a great and permanent mining industry. They have been developing for the last 10 years, and two companies have been engaged upon the gem-bearing dike. The English company, known as the New Mine Sapphire Syndicate, has been thus far the largest producer and the one most prominent before the public; but the other, the American Sapphire Co.—frequently called the Yogo Mining Co.—has been engaged in extensive prospecting and developing work. The Yogo dike is judged by qualified experts to be perhaps the greatest gem mine in the world. It extends four miles in length on the surface, and is a true igneous dike. If estimated

Longitudinal Section on Line AB.

The chief weight of the sets, however, is supported by the cables, to which each set is bolted. As the work was continued, new clusters of stulls were set wherever a permanent support could be found and likewise cables were fastened around them to hold the sets. It also became a necessary precaution to timber the stopes, and these timbers, set firmly in foot and hanging, serve to strengthen the shaft by studdles, bolts, and cables. The wall-plates and stulls are studded and braced, and spiked and bolted securely, while each set is bolted and studded to the next following, and the whole framework double-lagged. As soon as the permanent foundation for the superstructure has been placed each set will be cross-studded again, and timbers placed between the

down to 2,000 ft., below which possible working becomes questionable, and at an average width of only six feet—although it is often much wider—the entire content of sapphire-bearing rock would approximate 10,000,000 cubic yards.

Progress on the Rand.

In his presidential address before the Chemical, Metallurgical and Mining Society of South Africa, Mr. John Yates said:

To speak of the past is easy, but attempts to outline the future are often seen in the after light of developments to be merely caricatures. But so far as metallurgy is concerned, I think I may safely say that its development has in most cases exceeded expectations, that what was in past years hoped of it has been very often surpassed by actual accomplishments, and it may be that this pleasing trait will be maintained in the future. I have often thought that we would do well to thoroughly reconsider our impressions and practices every few years. Our practice at any time is based upon the particular conditions existent at that period, and, as the conditions change, so should our methods if we are to reap the full benefit of economic and other developments. Metallurgy especially has been advancing so rapidly of recent years, and working conditions in the Transvaal exhibit such a betterment compared with pre-war days that we cannot be too watchful of events or too critical in our inspection of our own work; propositions which would have been absurd in the old days may now, owing to the changes which have occurred, be feasible and payable schemes.

I shall not be at all surprised to see a few years hence, economic conditions permitting, 800 stamps or more under one roof on these fields. Such a mill need not necessarily be attached to one mine; for instance, three large adjoining deep level properties, each of 400 stamp capacity, and each independent so far as shareholders' interests are concerned, might advisedly have a joint 1,200 stamp-mill with suitable workshops, power station, and staff; this is what the unrivaled expanse of our gold beds calls for, and this operating on a large scale, a scale commensurate with that of the deposit, is what will have to be done if we have to work these reefs of ours to the depths they should be worked. We want larger properties, great joint mills, and a cheapening of our surface installations and our working costs. Turning now to detail, the use of the rotary sand distributor at work on the Langlaagte Deep is being attended with an improvement in extraction and we may expect to see it thoroughly tested. It is improbable, I think, that any further cyanide plants of the superposed type will be erected; the plants of the future are more likely to have only a few catching tanks, but a liberal number of treatment tanks, all more or less on one level, transference of the sand being effected by conveyor belts. When considering mechanical appliances, like the Blaisdell excavator, we have to bear in mind the cheapness, compared with most other mining fields, of our unskilled labor, and though the machine mentioned works well, I doubt that it can be installed in every case with advantage. Our tube-mills are doing good work and have proved a friend to the shareholders by increasing our profits. Our stamps are, as I have already mentioned, taking on more weight year after year and I am inclined to predict that we will see one ton gravitation stamps and even larger. Compared with the giant steam stamps of the Lake Superior copper mines with their capacity of 300 to 500 tons per stamp per 24 hours our stamps are but toys, and while I fully appreciate the difference in the quality of the product in the two cases I cannot help asking our metallurgists and engineers whether, under the conditions at present obtaining on the Rand, steam stamps are not at least worthy of consideration; I merely put this as a question, you will observe. True progress is often hampered by conservatism on the one hand and ill advised attempts to advance on the other; it is for us to try and avoid both of

these and I think it unfortunate that the continuous slime process has proved unsatisfactory on the New Goch because the failure may deter our engineers and financiers from venturing on any new lines unless absolute safety is assured, and this is often very difficult to guarantee in advance. The idea of all-slimes is in abeyance for the present, but with cheaper power and supplies we may expect a recrudescence of arguments in its favor; the new Usher-Adair process which has, I understand, passed trial runs satisfactorily will, it is to be hoped, cut down the present capital charge for slime tanks somewhat.

Concentration by Frue vanners on the Rand is about to become a thing of the past, the Langlaagte Estate having decided to discard them and fall into line with our general practice. The Wilfley table is still at work on the East Rand Proprietary mines and it remains to be seen whether its undoubted superiority to the vanner will enable it to hold its own. The treatment of residue dumps *in situ* has not been sufficiently successful to induce more than a very few mines to try it.

Relative to our mill construction the next few years will probably see timber battery posts superseded by steel, as the increasing weight of our stamps is likely to turn the scale against fear of trouble arising from crystallization of the metal.

Steel collar sets for our shafts are likely to become popular because of their great permanency compared with timber and the innovation at Kleinfontein in the way of steel sets throughout will be watched with interest. Our shafts are increasing in sectional area as we go south to the deeper zones and the irresistible demand for less capital outlay and for maximum profits will, of course, result in their number, relative to a unit area, being reduced to a minimum. The deeper we go the more costly will our development become because, among other things, of the increasing heat and the longer time occupied in getting to and from ends, etc., and for these and other reasons I foresee the laying out of our deeper levels with longer backs in conjunction with mechanical transport of the ore in the stopes. On hand versus machine stopping our experience on these fields has demonstrated, in my opinion, that we should use hand drilling in stopes under 5 ft. wide, and 2½ in. and larger drills in stopes over this size, and my own experience with 'baby' drills was such as quite convinced me personally that there was little scope for them on the Rand.

On this field we have been more than once accused of indifference to labor-saving devices, but, as a matter of fact, there is little in the shape of labor savers that we have not tried, some have successfully stood the test of practical application and have been adopted, others have failed ignominiously when put to the trial and have therefore been cast aside, and I believe that out of deference to public opinion, and with a whole-hearted desire to economize labor to the full, our engineers and managers are responsible for our having labor-saving devices at work at the present day which it would benefit us to relegate to the scrap heap. And after all, as has already been pointed out, these mechanical contrivances touch our labor army very slightly, and we must remember that both white and colored are affected and that labor savers do not necessarily mean a higher ratio of white to colored labor, nor yet increased profits.

ASPHALTUM IN VENEZUELA.—The production of asphaltum from Bermudez lake in Venezuela, which fell off greatly during 1902 and 1903 on account of litigation between the two American companies claiming the right to work the deposits, attained unusual proportions after the settlement of the legal complications.

The Combination Mine.—II.**Methods of Mining.**

Written for the MINING AND SCIENTIFIC PRESS
By EDGAR A. COLLINS.

Owing to the irregular shape of the orebodies, and their relatively great width, the problem of timbering the stopes merited a good deal of study. Good stulls are expensive and hard to get, anything over eight or nine feet having to be brought from the eastern slope of the Sierra, a distance of 200 miles. For this reason a stull 18 or 20 ft. long and 7 in. diam. at the small end will cost about \$5. Similarly, short heavy round lagging is obtainable from the piñon pine on Montezuma mountain, about six miles distant, at a cost of 50c. apiece. Conse-

tial chutes were placed at every fourth set of timbers, being thus spaced with 20-ft. centres. At first it was thought that it might be necessary to carry the stope in floors and to place a line of stulls every 20 ft. or so in height, to steady the walls, and to act as a break in case difficulty was experienced in drawing the ore from the stope. It was found, however, that the ground stood so well, and so little difficulty was experienced at the chutes, that the idea of the floors was abandoned, and the block of ground was carried as one continuous stope.

As has been already remarked, the orebody had no definite walls, and the limit of the ore was simply the point at which the silicified material was too low-grade to pay. This limit varied in an extraordinary manner and it was found necessary to watch the work closely.

Fig. 1. Method of Stopping 'Old Shaft' Ore-Shoot.

Fig. 2. Method of Stopping No. 3 East Stope.

quently, sawn lumber is used to a great extent in the mines. This is of poor quality and costs \$15 to \$50 per thousand, depending on the stock that the local yards are able to carry.

In the upper levels of the Combination mine, where the ore is oxidized and the silicification especially pronounced, the ground is ideally easy to support. The silicified material is all wedged together and a minimum of timbers is necessary. It was therefore decided to stull and lag the cutting-out stopes over the level, and to fill with broken ore, as the stope progressed. As a further economy it was decided to timber permanently only alternate levels, and to leave arches on the intermediate levels that could be stoped out from the lower of each pair of levels. The following method was therefore established. At the first or 80-ft. level, after the drift was driven to the end of the ore-shoot, hitches were cut and short stulls were set in place, with the usual short head-boards. These were covered with lagging and a second stope commenced. At the same time the stope was widened on an incline above the timbers until the full width of the orebody was reached. The broken ore was allowed to remain in the stope, sufficient only being drawn off to allow room for the men to work. Substan-

As it was absolutely impossible to tell pay-ore from worthless vein-stuff by its appearance, recourse was had to continual panning, the gold being sufficiently free to act as a fairly reliable guide. Samples were therefore taken from every working face each morning, and panned by the mine foreman, who then made out a short report, which was turned in at the office. To further keep in touch with the ore, flat holes were drilled 6 ft. apart and 1 ft. deep, at intervals of 12 ft. in height, on both walls of the stope. The drillings were saved in two parts, those from the first two feet, and those from the second two feet, and were assayed as separate samples. If the results showed ore, the holes were blasted and the operation repeated; otherwise, the holes were left unblasted. As the stope progressed, the ore was found to extend farther and farther into the sides or walls of the stope, and eventually the stope was over 50 ft. wide at one end. By working the stope in sections, and by keeping the 'back' arched, no difficulty was encountered, nor was there a man hurt while the block of ground was being removed. Finally, a hole was made through the last 15 ft. or so to the surface, and the remainder of the arch of ground removed by underhand stoping.

On the second or permanent level (130-ft. depth) the

whole of the pay-ore was taken out to the full width, and the level then timbered with either square sets or stulls, according to the width of the orebody. A second stope was then commenced, and continued, exactly in the same way as the first stope until within six feet of the level above (1st level). Raises were then put through the remaining arch to the level under each chute, after which tramming on the upper level was abandoned. The broken ore remaining above the upper level was run down into the lower stope until the arches over the level were reached. The arches were then stoped out as fast as they were exposed by drawing the broken ore, and at the same time any ore still remaining on the sides of the stope was removed. At the present time, March, 1907, the lower stope is full of broken ore and open quarrying is still going on around the sides. The 'glory hole' left is about 120 ft. long and will average about 30 ft. wide. After all the ore has been drawn out of both upper and lower stopes, it is proposed to fill the excavation above the 130-ft. level with waste from surface. This will be obtained partly from the present dump, and partly from future 'dead work.' It might be of interest to remark that the old incline shaft passed through the centre of both the first and second level stopes, and thus afforded excellent ventilation. A narrow stope on one of the high-grade seams of ore had also been taken for a short distance from the old incline shaft, through the middle of the block of ground. These 'old workings' caused us some little trouble when the big stope was commenced, and care was required to avoid 'caves,' but practically no timbering was necessary.

The above program of stoping was planned for the sulphide as well as the oxidized ore, down to the 230-ft. level, with the difference that in the stopes in sulphide ore, where the silicification was not so strong, and the ground therefore weaker, permanent timbers were placed at each level (50 ft. apart), and chutes were placed with centres only 15 ft. apart. It was planned to fill these stopes with waste from other parts of the mine, after the broken ore had been withdrawn. Below the 230-ft. level, the vein flattens in dip to about 38° and a different method of stoping would have to be employed. No definite plan had been decided on, but it is probable that it will be necessary to lower the ore on inclined movable tracks, laid on the foot-wall of the stopes, as is being done elsewhere, notably on the Rand in South Africa.

The Combination mine has 14 shafts and 7,100 ft. of levels. Only two of the shafts have ever been used for hoisting. The others are mainly prospecting shafts that were sunk to establish the position of the lode. Of the two working shafts, No. 1 was the original incline shaft, which constituted the main opening for the first two years of the mine's existence. It was sunk on the rich stringer that was exposed in the shallow 'tunnel' previously mentioned, and followed it from surface to the 230-ft. level. For the first 80 ft., the vein dipped slightly to the southwest. The next 50 ft. showed the streak almost vertical. From a depth of 130 ft. to 210 ft. the average dip was about 70° to the northeast. At the 210-ft. point the vein flattened to about 38° and the average dip between the 230 and 280-ft. levels is about 35°, also to the northeast. At the 280-ft. level, which is the lowest point at which the vein is exposed, the dip is about 30 to 35°. Below this level the lode has not yet been exposed. In June, 1905, a main vertical hoisting-shaft was started. The shaft, which was 9 by 5 ft. inside timbers, was divided into a hoisting-compartment of 4 ft. 8 in. by 1 ft., and a manway of 4 ft. 8 in. by 2 ft. 10 in. Between these a narrow compartment, 8 in. wide, and the full width of the shaft in length (1 ft.

8 in.), was divided into a box for the counterweight, and compartments for pipe and electric wires.

This shaft was sunk for the first 20 ft. only, the balance of the distance being raised from cross-cuts driven from the main levels of the mine. A small irregular shaped raise about 3 by 5 ft. was carried up from each level, and after connection was made, a chute was put in and the shaft trimmed to full size. In this way the shaft was sunk cheaply and expeditiously during the delay in arrival of the electric hoist, all broken rock being hoisted through the old shaft. The average cost of sinking this shaft to the 230-ft. level, including breaking, raising, mucking, timbering, and all supplies, was \$22 per foot. The cost of the timber alone amounted to \$9 per foot. From the 230-ft. level to the present bottom (400 ft.) the shaft was sunk by day work. Practically no water was encountered. The total cost per foot, exclusive of hoisting but including timber and all supplies and labor was \$23.12 per foot.

As a general rule development work in the lower levels was cheaper than in the oxidized zone. This was due to the less degree of silicification. Cross-cutting beyond the limits of the silicification is extremely cheap, the rock on the lowest level being much decomposed. For this reason it was not considered economical to use machine-drills in the development work. For the same reason the use of the diamond-drill for prospecting the adjoining country, as used in the mines of Tonopah, was not favored. The average cost per foot for driving, raising, sinking, and cross-cutting at the Combination, including breaking, supplies, track-laying, and timbering, where necessary, is as follows:

Average cost per foot driving and cross-cutting	\$5.50 to \$6.00
" " " " raising on lode	6.00 to 6.50
" " " " sinking winzes on lode	8.00
" " " " sinking prospecting shafts (practically no timber, and in soft rock down to 120 ft.)...	7.50 to 8.00
Cost of sinking main shaft, 9 by 5 ft. inside timbers, 400 ft. deep, including all labor and supplies, but no hoisting charges.....	23.12 per foot
The cost of the timber alone.....	6.50 per foot

There are four separate ore-shoots in the Combination mine. These are known respectively as the Old Shaft, No. 2 East, No. 4 West, and Jannary shoots. The Old Shaft shoot has up to the present produced the bulk of the tonnage already treated. It is seen as the 'Glory Hole' on surface, and has been opened up on the 80-ft., 130-ft., and 180-ft. levels. On the 80-ft. level it is roughly 100 ft. long by 20 ft. wide, and is pretty thoroughly oxidized. On the 130-ft. level it is only about 75 ft. long by about 30 ft. wide, while the ore contains a larger percentage of sulphides. On the 180-ft. level, the ore-shoot is about 50 ft. long and 35 ft. wide where cross-cut. Here the general outline of the shoot appears to be triangular. Below this level the ore-shoot has not been found, and it may possibly be cut off, by the flatter-dipping No. 4 ore-shoot, to be described later.

The No. 2 East shoot is the longest continuous ore-shoot in the mine (about 320 ft.), and certainly one of the longest, if not the longest, in the district. For convenience it has been divided into two parts. The longer and more southerly portion, which follows the east, or hanging wall, side of the silicified zone, is known as the No. 2 East stope. This averages only three or four feet wide of pay-ore, bounded on the east side by a thin shell of almost barren silicified material, adjoining the soft bluish country rock, and on the west side by the main mass of the low-grade silicified zone. There is no defined line between ore and waste. The more northerly portion of this shoot extends into the silicified material for (as previously described) an average width of 20 ft. and a length of about 150 ft. This is known as No. 3 East stope. At the present time the whole shoot is exposed

only on the 130-ft. level, where it is fairly well oxidized. On the 180-ft. level No. 3 East shoot has just been found and the ore is still well oxidized. It has not yet been cut on the 230-ft. level. The No. 2 East stope portion of this shoot has not yet been found on the 180-ft. level, but has been opened up on the 230-ft. level, for a distance of about 70 ft. At this point it is partially oxidized and of lower grade, but payable. Below this level the ore-shoot has not yet been found.

The No. 4 West shoot lies immediately west of the Old Shaft shoot, and parallel to it. It occurs in the same silicified mass, and is only separated by about 30 ft. of barren lode matter. It has been opened up on the 80-ft., 130-ft., and 180-ft. levels, and it is probable that the main ore-shoot, as exposed on the 230-ft. and 280-ft. levels, is a continuation of this shoot of ore, as it shows the same well defined flat dip to the northeast. On the

on the 130-ft. level, some 300 ft. northwest of the Old Shaft shoot, on what is known as the January lode. This is the northeast extension of the horseshoe-shaped zone of silicification that enters the west side line of the Combination claim, about 350 ft. north of the main shaft. This ore-shoot occurs in the oxidized and silicified material, and is about 100 ft. long by about the width of the drift (5 ft.) The shoot in all probability extends practically to surface, a distance of about 100 ft., as the adjoining ground in the January mine has been stoped right up to the line, from this level to surface. A winze has been sunk some 47 ft. in ore, but otherwise the ore-shoot has not been developed below the 130-ft. level.

The following detailed mining costs, covering operations at the Combination mine during the year 1906, should prove interesting to those who may be contemplating the operation of mines in the district, and should

Fig. 3. Showing Ore Shoots on the 130-Ft. Level.

80-ft. level the ore-shoot is a lens of high-grade oxidized ore, about 60 ft. long, and about 15 ft. at the widest. On the 130-ft. level it is a little longer and better defined, but averages lower in grade. On the 180-ft. level, the orebody is entirely sulphide in character, and averages a higher grade, and has a length of about 100 ft. At the eastern end the lens narrows to a thin wedge, which is overlapped by a second longer ore-shoot. It is this second shoot that produced the large tonnage of high-grade sulphide ore shipped from the mine. It is a curious fact that this "all-sulphide" ore-shoot does not extend up to the 130-ft. level, although high-grade ore was stoped to within two feet of the track. On the 130-ft. level, the pay-streak is represented by a narrow clay 'gouge.' On the 230-ft. level the ore-shoot is about 225 ft. long, of which some 75 ft. was exceedingly high-grade. On the 280-ft. level the ore-shoot has been followed for a length of 100 ft. Below this level the vein has not yet been proved, but a cross-cut has been driven at the 380-ft. level to intercept the vein. At the time that I left the mine (March 1, 1907) this cross-cut had been driven a distance of 350 ft., and it was expected that the vein would be cut near the 400-ft. point. This was estimated on the supposition that the vein would continue with a dip of about 30° to the northeast.

The fourth shoot of ore, known as the January, occurs

give a good idea of the comparative expense of the various items shown:

Mining Costs per Ton During Year 1906.			
Foreman and shift-bosses...	\$0.199	Assaying	\$0.162
Shaft sinking	0.305	Surveying	0.057
Driving and cross-cutting...	0.940	Tracking and ditching ..	0.038
Raising	0.0165	Tools	0.045
Sinking winzes	0.029	Watchmen	0.118
Surface trenching	0.008	Maintenance, repairs	0.056
Stoping	0.913	Pumping	0.017
Hoisting and dumping	0.139	General	0.002
Tramming and mucking	0.365	Total	3.709
Mining	\$2.41		
Development	1.30		
Total	\$3.71 per ton.	Of this 82¢ is for labor alone.	

It will be noticed that in spite of the high price of labor—probably the highest paid in the world—and the heavy cost of all supplies, especially timbers, the expense of breaking ore and hoisting it to surface is not unusually high, even including development charges. The explanation of this is the fact that the ground at the Combination mine is full of soft shattered seams, which both drill and break exceptionally well, while the method of stoping employed requires comparatively little timber. Prospecting, outside the limits of the silicified lode, is cheap, because the rock is soft and decomposed. It must also be remembered that the mine is practically dry at its present depth, and the cost of pumping is therefore insignificant.

The mill has been described in detail on several occasions, particularly by Mr. F. L. Bosqui, the consulting metallurgical engineer for the company, and it is therefore unnecessary for me to mention it further than to repeat that it is a 20-stamp mill, employing amalgamation, concentration, and cyanidation to treat the mixed oxidized and sulphide ores. Before cyaniding, the pulp is separated into sand and slime, the sand being treated by leaching, and the slime by the Butters vacuum-filter method. By mixing the ore from the various parts of the mine, the grade of ore milled is kept at about \$40 or \$50 per ton, the value being almost entirely in gold.

Record Sinking.

The work done in the two shafts of the Brackpan Mines Co., at Johannesburg, furnishes a new record for rapid sinking. In July the No. 2 shaft was sunk 204 ft., which is one foot better than the record for vertical shaft-sinking, made by Leslie Simson at the Simmer West in 1898. At the Brackpan No. 2 shaft, 210 ft. of timbering was placed in position during July. In the No. 1 shaft the same company has averaged 143 ft. of sinking during six months, and an average of 161 ft. during the three months ending with June. This shaft is of the seven-compartment type, and is 8 ft. wide by 39 ft. long. The Simmer West shaft has five compartments, and measures 7 ft. 6 in. by 31 feet.

Since the beginning of the year the Brackpan Mines record has been:

	Sunk. Ft.	Timbered. Ft.
No. 1 Shaft.		
January.....	98	83
February.....	131	127
March.....	143	158
April.....	148	135
May.....	186	196
June.....	150	143
July.....	125	135
No. 2 Shaft.		
January.....	77	31
February.....	49	57
March.....	100	76
April.....	125	135
May.....	152	166
June.....	170	158
July.....	204	210

The following additional particulars will be of interest:

	No. 1 Shaft.	No. 2 Shaft.
Started operations.....	May 12, '05.	June 1, '05.
Engines started.....	Sept. 16, '05.	Dec. 20, '05.
The depth then being.....	60 ft.	96 ft.
Depth on Aug. 6, '07.....	2,800 ft.	1,930 ft.

Bad ground and much water necessitated large pumps and heavy timbering in No. 2 shaft. This delayed progress from October, 1906, to April, 1907. Since then the average sinking has been 162.7 feet.

Credit for this good mining engineering is due to Charles B. Brodigan, the manager of the mine. Mr. Brodigan is an Associate of the Royal School of Mines.

COMMERCIAL asbestos includes fibrous minerals of two distinct types. The true asbestos is actinolite or tremolite and belongs to the amphibole group, and with it may be placed the other fibrous amphiboles, anthophyllite, and crocidolite. The more important asbestiform mineral, however, is the fibrous variety of serpentine known as chrysotile. Both fibrous amphibole and chrysotile possess qualities which peculiarly fit these minerals for use in the arts. The term asbestos, meaning noncombustible, thus has come to stand for mineral fiber which is more or less resistant to both heat and acids. Although the chrysotile, by reason of its chemical composition, may be affected by very high temperature and strong acids to a greater degree than the amphibole, the greater strength and flexibility of the chrysotile fiber make it the more valuable of the two.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

Pearlite or Pitchstone was sent by C. B., of Reno, Nevada.

A specimen of Gneiss was sent by C. D. C., Quartzite, Arizona.

J. G. of Gem, Idaho, sends a piece of Quartzite, carrying some pyrite and galena.

The two specimens from Sisson, Cal., marked O. L. H., are: No. 1, serpentinized rock; No. 2, Rhyolite Tuff.

E. E. N., of Camacho, Mexico, sends: No. 1, Hornblende Gneiss; No. 2, Hornstone; No. 3, Quartzite; No. 4, Quartzite.

The specimen from Nogal, New Mexico, marked C. E. M., is rock containing disseminated grains and crystals of pyrite.

Specimens from the P. D. Co., Silver City, New Mexico, are: No. 1, yellow Ocher; No. 2, Diorite; No. 3, Feldspar Porphyry; No. 4, Quartz, with some Limonite and Malachite; No. 5, Feldspar Porphyry; No. 6, Epidote rock; No. 7, Quartzite; No. 8, Andesite.

The rocks from Sinaloa, Mexico, marked D. A. McD., are: No. 16, Andesite; No. 17, Quartz Porphyry; No. 18, Andesite; No. 19, Andesite; No. 20, Basalt; No. 21, altered Rhyolite or Andesite; No. 22, Andesite; No. 23, Andesite; No. 24, Rhyolite Porphyry; No. 25, Dacite, No. 26, Basalt; No. 27, Rhyolite; No. 28, Andesite; No. 29, massive Hematite.

VARNISH is a composition or an amalgamation of fossil resins, or gum, linseed oil, and spirits of turpentine, with a certain per cent of oxides worked in to serve as driers. This is varnish in general and applies to all kinds, the proportions and treatment varying according to the purposes for which the varnish is to be used. Gum, strictly speaking, is only properly applicable to those that are soluble in water, such as arabic, senegal, tragacanth, aloe, etc., all of which exude from live trees; but the gums of fossil resins used by the varnish-maker are petrified, only dissolve under great heat, and are the exudations from trees which are extinct. This resinous deposit is found buried in the earth, having laid there from a period before the creation of man. Different kinds are used for different products, the principal of which are Animi or Zanzibar, Sierra Leone, and Benguela; these are found in Africa and the East Indies. Kauri, however, is the resin most used; this comes from New Zealand, and began to be exported in quantity after the Australian gold discoveries. It is estimated since then up to 1904 \$65,000,000 worth has been shipped, and in that year \$52,509,085 worth was shipped to the United States and the United Kingdom. Linseed oil, the other important ingredient, needs no description. It is well known to be the expressed juice of flax seed. This is prepared by boiling, and different makers have different ideas as to the amount and manner of boiling prior to its introduction into the melted gum. Turpentine is used as a dilutant to render the treated gum and oil fluid enough to spread the varnish with a brush, and when the dilutant evaporates it has performed its mission and leaves the resultant film of gum and oil, or, in other words, it leaves all there is of what is essentially varnish.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

COMBINED STAMP AND GRINDING MILL.—No. 866,600; George C. Richards, South Berkeley, Cal., assignor to Western Mill & Machine Co., a Corporation of California.

A stamp-mill having in combination a rotary pan, said pan having a trough the outer wall of which is provided with openings for the delivery of crushed material, and the inner wall forming a central cone, a driving shaft passing through the centre of said cone and fixed to said cone, a series of successively arranged die-members in said trough, a stamp-member, a fixed support on the pan, and means forming a horizontal hinge about which said stamp-member may rise and fall to engage successive of said die-members.

AMALGAMATOR.—No. 866,084; William H. Stiglitz, Louisville, Kentucky.

An amalgamator, comprising an approximately circular case having a mercury-holding basin and provided with means for the admission of water under pressure to its interior, said casing also having, within its interior, walls relatively arranged to provide a centrally disposed sluice column, a series of perfectly flaring outlet columns around said sluice column and a chamber surrounding the base of the sluice column and arranged between the same and the outlet columns, said columns and chamber each opening into said basin and the walls of said chamber and the outlet columns having openings for the admission of water thereto.

APPARATUS FOR EXTRACTING MINERALS FROM ORE.—No. 865,027; Oscar A. Ellis, San Francisco, California.

An apparatus for separating minerals from ores, having in combination, a long, inclined, open chute or launder, provided with riffles, and a precipitating box located adjacent the lower end thereof, whereby a mixture of ore and chemical solution will flow by gravity down the launder

and through the precipitating box together with means for passing an electric current through said precipitating box.

PROCESS OF ROASTING FUSIBLE ORES.—No. 866,580; Albert G. Davis, Washington, District of Columbia.

The process of roasting fusible ores which consists in exposing them first to a high temperature in a reducing atmosphere and thereby preventing fusion, and then to an oxidizing gas, substantially as described.

CONVERTER.—No. 865,671; Ralph Baggaley, Pittsburg, Pennsylvania.

A tuyere having a removable sleeve or tube extending into and through the tuyere orifice and having an accessible tool-seating portion.

DEVICE FOR SHARPENING ROCK-DRILLS.—No. 866,041; Elias Lewis, Denver, Colorado.

In a device for sharpening rock-drills, the combination with a suitable base of a frame erected thereon, four levers fulcrumed in said frame, dies secured to the converging extremities of the short arms of said levers, a cylinder located on said base, a piston having a reciprocating movement in said cylinder, means for admitting and exhausting air or steam in and from said cylinder, a piston rod secured to said piston, guide ways erected on said base, a cross head having a reciprocating movement in said guide ways, being connected with said piston-rod, connecting rods pivotally connected with said cross head and with the extremities of the long arms of said levers, and suitable means for adjusting the length of said connecting rods.

Power Transmission by Manila Rope.

By G. P. HUTCHINS.

The use of rope for transmitting power is one of the most recent developments of modern engineering. One of the causes for late acceptance of this cheap and ready method was the lack of reliable and sufficiently flexible rope of reasonable endurance. Since this means has been perfected, it has displaced gearing and belting in a great number of installations.

In general terms it may be said that where the distance between driving and driven shafts is not less than 10 nor more than 1,200 ft., fibre rope running in properly grooved sheaves offers the cheapest, most efficient, and most durable

the total destruction of fibres by internal movements. No rope can long endure this destructive abrasion without lubrication. The degree of skill with which the lubricant is applied and its character, determine to a great extent the rope's durability. External dressings do not soak into the places where the real friction takes place, so that their effect is merely local, leaving the interior dry. Soaking the strands in tallow before laying up gives imperfect protection. Tallow has not body enough to cling to the fibres. It works out or dries out. The free fatty acids contained in tallow attack the fibres, and if it becomes rancid it causes the rope to rot. 'American' rope is lubricated by thoroughly soaking the core as well as a number of inner yarns of each strand in a bath composed mainly of flake graphite, mixed

Fig. 1.

Fig. 3.

means of power-transmission. No matter at what angle the driver may stand to the driven shaft, power will be delivered at minimum loss and with greatest certainty.

Fig. 2 shows an over-roof drive between separated buildings, transmitting about 80 hp. around corners and at angles quite impossible to any other known form of drive. When shafts are even slightly out of alignment, the wear and noisy pound on any form of link connection are prohibitive. Belts, under such circumstances, cannot be kept on their pulleys. Rope, however, owing to its flexibility and uniform figure of contact, can adjust itself to new positions in the sheave-grooves, thus permitting a considerable degree of eccentricity without derangement of service.

Transmission rope made from manila hemp is particularly

with fish oils of a neutral character. Fig. 4 shows a cross-section of a four-strand 'American' rope, the shaded portions indicating the graphite lubricated core, or heart, and yarns of each strand. This flake graphite is precisely the same material which has established its reputation among engineers for the lubrication of engine-cylinders and bearings. The lubricating compound permeates all the fibres of the completed rope, lodging in the hollows, smoothing out the uneven places, and forming layers of unguent between all fibre and yarn surfaces. This constitutes perfect lubrication. After a short period of service, enough of this mixture is soaked into the external fibres to form a glossy black metallic coating on the outside of the rope, which is absolutely impervious to water. Ropes thus lubricated re-

Fig. 2.

Fig. 4.

subject to internal wear unless scientifically lubricated with the best kinds of material. Weight for weight, these ropes are as strong as steel in the direction of their length, but have little transverse strength owing to their cellular structure. When the stems are sub-divided by machinery, the fibres are made peculiarly rough and splintery. When these rough surfaces are bent around a sheave, they slide on each other with much force, every part of the rope section rubbing upon its surrounding fibres. This may happen many times in one minute, according to the distance between shafts. It is absolutely destructive to the rope, the fibre being wholly ground to powder. If the strands of a worn rope are untwisted, a quantity of fine powder will be found in the interspaces between the yarns produced from

quire no dressing or any attention as to maintenance. If not absolutely abused, they will last ten years and even longer.

For driving the mainshafts on a series of different floors, from an engine in the basement or in an adjoining engine house, the English system is to be preferred. Such an installation for a cotton mill is shown in Fig. 3. This shows the simplicity and compactness of power distribution and the advantages over driving by intermediate stages from floor to floor, in which all the upper floors are shut down by break down on the lower floor. This vividly illustrates the enormous factor of safety provided in the great number of individual ropes, precluding all possibility of the engine's running away from break in the transmission.

Editorial.

THE RIGHT to cut timber on the public domain is a much mooted question among miners. On another page we take pleasure in quoting Mr. Samuel Pratt, United States District Attorney of Nevada, and to his statement we append a few remarks, which will put the present status of the question fairly before the mining community.

PROSPECTING with the diamond-drill has made great advances in recent years, and in the wake of wide experience there has come a better knowledge of the methods likely to give the most satisfactory results. To have a good tool is one thing; to use it effectively is another. In this issue, Mr. Lewis T. Wright, general manager for the Mountain Copper Company, gives advice based upon his personal experience. It will prove useful to mine operators.

IT IS ANTICIPATED that the gold production of the Transvaal in 1907 will approximate 6,290,000 fine ounces, worth \$126,000,000. This is more than double the output made in 1903. At the present time the average monthly yield is 550,000 ounces, valued at about \$11,000,000. There is good reason to believe that the Rand has reached the zenith of its productiveness, and that succeeding years will see a large, but declining, output.

RIVERS have a romance of their own. By their names they suggest the early explorers that first found them; in their associations they recall whole chapters of human history. Of all rivers, the most mysterious, the most historic, the most beneficent, is the noble stream that makes Egypt. We associate the Nile with the poetry of the past and the engineering of today, but it is always as a factor in regional irrigation, never as connected with mining. For this reason the article by an encyclopedist like Mr. Alexander Del Mar will be read with interest.

FROM MEXICO our regular correspondent writes concerning the progress being made at Guanajuato. It is a pleasure to publish the good news. The group of energetic technical men who took hold of the old mines of the Veta Madre and rehabilitated them, substituting modern machinery for the *malacate*, and the cyanide annex for the *patio*, interjecting the virility of today in place of the complacency of yesterday—this group of Anglo-Americans, mainly American, deserves the reward of financial success and the esteem due to professional ability. It has not been plain sailing, but by keeping the prow pointing steadily in one direction the haven has been reached and magnificent holes in the ground have been made once more profitable mines.

The construction of the branch railroad from Marfil, linking Guanajuato with the outside world, is an important step forward; so also is the Porfirio Diaz tunnel, designed to take any excessive rainfall and to prevent a flood such as that of July 2, 1905. To the Mexican authorities our countrymen owe a good deal of help in their efforts to develop the mineral deposits of Guanajuato, and the recognition of this fact will be accorded gladly.

OUR CORRESPONDENT at Denver makes some humorous remarks concerning certain phases of journalism as they are exemplified by a contemporary at Colorado Springs. The responsibility of publishers for the advertisements they display in their papers is a matter that has both its humorous and its serious side, and it is possible that the serious consequences are emphasized most effectively in a humorous way. Mr. T. T. Read, our correspondent, who is about to take an appointment in the University of Tokio, is not without the salt of humor, without which life would lose its savor.

FIVE THOUSAND revolvers, estimated to have cost \$15,000, were taken out to sea and thrown overboard off Sandy Hook on September 28. All of these were weapons seized by the police in New York within the last year and a quarter. The heterogeneous collection of pistols, a veritable arsenal of crime, was collected mainly from Italians during a recent crusade against the carrying of concealed weapons, and from the Chinese during the Tong fights. Formerly revolvers confiscated by the police were sold to pawnbrokers and it was found that they were returned to bad use. By the act of the last Legislature it was provided that the Commissioner of Police might dispose of such property by destroying it. He did so, effectively, and rid the world of a few unnecessary instruments of destruction.

Smelter Smoke.

A DISPATCH from Butte states that Oliver T. Crane, Master in Chancery, who was appointed referee to hear the testimony in the case brought by farmers in the Deer Lodge valley against the Washoe smelter of the Amalgamated Copper Co., has submitted his report to Judge Hunt of the United States Court, and that on October 25 objections to his findings are to be heard, preparatory to a final judgment. The referee finds that the complainants, who are farmers and landowners in the valley over which the smoke from the smelter is supposed to pass, have been damaged, and the plaintiff, F. J. Bliss, is adjudged to be entitled to special damages in the sum of \$350, that amount being loss sustained by him by reason of the injury done to his land by the smoke. The main conclusion of the referee is that a tremendous injury and practical paralysis of the business of the State of Montana would follow such an injunction as has been asked for by the complainants, and that the farmers themselves would suffer greater loss by such suspension than they do now from the fume. It remains for Judge Hunt to decide whether an injunction is to be granted. As most of the mines at Butte are dependent upon

this smelter for the treatment of their ore, the final decision will be awaited with keen interest. Incidentally, we may add that while the referee finds that damages amounting to \$350 were caused by the smoke, the fighting of this case by the Amalgamated Company has cost fully \$500,000, the transcript of evidence covering 27,000 pages of typewritten matter. It is also known that the complainant sold his ranch and left the Deer Lodge valley, going to Idaho, and that he came back and bought another ranch before the suit was started. In other words, this is a good example of an industry essential to the well-being of a community, and, indeed, to a whole State, being harassed by men whose public spirit can be called in question, and whose motives are distinctly anti-social. We hope most sincerely that it may be established that farmers and others are entitled to full payment for any damage done to them, but that they cannot use that damage as a weapon for blackmail or for hindering the metallurgical operations so essential to the development of the West.

Speculation or Investment.

IN OUR LAST ISSUE a reader took exception to a certain statement of ours in which we had said that mining was a sane speculation or a silly gamble, but never an investment. At about the same time an experienced mining engineer happened, in conversation, to express regret that anything so sweeping should have been said in print, because it was true—painfully true—and calculated to do harm to legitimate business. To this we demur, frankly and cheerfully; the economics of mining is a study based upon scientific investigation, therefore the recognition of the truth cannot be injurious; on the contrary, nothing is so harmful, so utterly destructive, as make-believe—the acceptance of things as they are *not*. Mining is based on the application of science to industry, not upon the utilization of imagination in promotion or of fancy to finance; therefore, the more we get alongside of facts, the safer we shall be and the more successful—in the long run—in making money by digging ore.

Speculation is a more or less risky use of money in the expectation of considerable gain, or any business involving such a use of money. Investment is the laying out of money productively, especially in a permanent manner. In the first the emphasis is on the idea of riskiness and large gain; in the second, the emphasis is on productiveness and permanency. To make the distinction clear and brief, it may be said that a speculation is the temporary use of money for large gain, which involves commensurate risk; while an investment is a permanent placing of money at a small interest, which promises a correspondingly less chance of losing the principal. Now, we do not lay stress on the riskiness of mining or the impermanence of it save as it balances the large gain to be made by the judicious use of knowledge and experience. Surely it will do no harm to recognize the essential facts pertaining to the industry in which we are all so keenly interested. Shall we live in a fool's paradise

and call a mine that fluctuates in value from day to day, that may be worth either ten times as much a year hence or one tenth its present valuation, that may suffer from fire, from a creep, from flooding, from sudden change in the ore, from any one of the many vicissitudes incidental to such enterprises—shall we call it an 'investment' and insist that it has a fixed value, superior to the vagaries of ore deposition, the chances of management, or the tyranny of nature? If we do prefer to shut our eyes to facts, we shall do as others have done, and do, continually. Men think all men mortal but themselves; they regard all mines as likely to peter out but their own. So they get nasty jars, and lose money, and swear that mining is a heedless gamble. That is the other extreme. You can make it a gamble by disregarding all the precautions that make it a sane speculation, but, we insist, a man cannot add a cubit to his stature by much thinking, and he cannot metamorphose a speculation into an investment by make-believe.

A striking example is available. When the gold-bearing banket of the Rand was sampled and tested, when the orebodies at Johannesburg had been measured and assayed, when the metallurgical reduction of the ore had been decided upon, it was stated, confidently, by many first-rate engineers, and by more promoters, that here at last we had gold veins that were regular as coal seams and mining enterprises that were as safe as British Consols or United States bonds. So there was a boom; this was in 1895 and at recurrent intervals in later years. The shares of the mining companies went kiting, naturally, for they were capitalized on earnings estimated at 20 or 25 per cent, and when the public had been filled with ideas of a safe investment, of a sure thing, of a form of gold mining the like of which the world had never seen, they naturally thought that a return of 1 or 5 per cent was enough. Capitalists and their followers talked of amortization; actuaries' tables were brought into service; the nicest kind of elaborate calculations were made of the life of the mines, of their ability to repay the capital invested, and of furnishing the required interest on the "investment." Investment, of course, no more of your silly gambling in American or Canadian mines; in South Africa they had the real thing, beyond a peradventure. It was as good as the Bank of England, and more profitable. And the sequel; need we tell it? No chapter in the history of mining is so significant or so bespattered with a tawdry romance. The ore proved patchy—as elsewhere; the lodes were interrupted by dikes—as elsewhere; the orebodies proved to be erratic—as in the risky mines of other regions; the estimates of ore reserves in several cases proved fallacious—as anything human is fallible; the calculations of profits turned out as disappointing in many instances as in the less regular, less simple, less persistent veins exploited in America or Australia. No new type of gold mining had been discovered; it was the old story—big risk and big gain. On the portals of the mines at Johannesburg it might be written, "Dead things will crawl; it is better to be sure than sorry." And so that bubble is exploded and the irides-

cent films of it have made gay the nights of London, Paris, and Berlin. It was a grand gamble; the misrepresentation of fact and the ignorance bred of make-believe had gone their inevitable way; never an investment, mining on the Rand became a wild debauch of speculation; shares were run to five or ten times their worth, men lost money as they did at Monte Carlo or Ostend, the supposititious investments in South Africa were no better than the chances offered to speculators at Cripple Creek, at Bingham, in Arizona, in Nevada. Many mining engineers, lured by the opportunity of participating in big promotions, others carried away by an honest enthusiasm, did, indeed, give their authority to the over-capitalization and, indirectly, to the wild dealing in shares, consequent upon fanciful notions as to the character of the mining enterprises at Johannesburg; but not all. There were many who spoke out fearlessly, and foremost among them was Mr. J. H. Curle, who has seen his warning prove true and is now in the ungracious position of being able to say—but he does not bother to say it—"I told you so." This reference is interjected just to indicate that everyone was not deluded and that the man who pins his faith to facts is likely in mining to win both money and reputation. However, now that the truth is known, the Rand is on a safe basis. People no longer deem 3, 4, or 5 per cent sufficient interest and they do not buy stock to put it in a safe as a heritage for their children; they recognize that mining on the Rand, if properly conducted, affords good chances of making money rapidly, and that the risk is commensurate with the chance of gain; in fact, like mining anywhere else, it is a sane speculation.

PRODUCTION OF GOLD in Australasia continues to decline. According to statistics received for the first half of 1907, there is a decrease of 170,000 ounces as compared to the first half of 1906. Of this decrease 66,000 oz. is due to the diminishing production of the gold mines in Western Australia, particularly Kalgoorlie. No new mining districts have been discovered and many of the largest mines exhibit traces of exhaustion. This fact has become steadily more apparent, and among other suggestions, it has prompted a plan for converting the State into one huge mining company. This idea is a development of the argument employed in support of the big water scheme for supplying the gold-fields, which was carried out successfully by the State. While this audacious proposition is not likely to be carried out, it does indicate the recognition of a waning gold mining industry. In Victoria there is a decrease of 55,000 oz., due mostly to the lessened contributions from the older goldfields of Bendigo, Ballarat, and Maldon. In Queensland the decrease is 25,000 oz., traceable to a smaller output from Charters Towers and Gympie. In New Zealand the decrease is 10,000 oz., despite the maintenance of steady production by the great Waihi mine. The dredges in Otago and on the West Coast are not doing as well as formerly. In New South Wales only is there an increase; this amounts to a trifle over 5,000 oz. and represents the by-product from the smelting of copper and lead ores.

Personal.

ROWLAND C. FEILDING is in Newfoundland.

FRED B. REECE is on a tour in Spain and Portugal.

NORRIS ENGLISH has left San Francisco and is in Utah.

N. C. BONNEVIE has returned to Denver from New York.

SAMUEL NEWHOUSE has returned to Salt Lake from Europe.

W. B. WAINWRIGHT has returned to London from Mexico.

ROBERT E. CRANSTON has an office in the Physicians Bdg., Sacramento.

CLAUDE T. RICE is now on the staff of the MINING AND SCIENTIFIC PRESS.

D. J. A. REES has been appointed manager of the Tuco Cheira mines, in Peru.

M. O'ROURK is superintendent of the Gold Prince mill at Animas Forks, Colorado.

FORBES RICKARD is examining tungsten deposits in Boulder county, Colorado.

J. M. ELMER, of Cobalt, Ontario, is at the Old Hundred mine, near Silverton, Colorado.

WALDEMAR LINDGREN was at Portland recently, on his return from Ketchikan, Alaska.

E. C. LIMBACH, of Denver, has gone to Tulameen, B. C., to investigate a platinum property.

SCOTT TURNER has been appointed superintendent of the Granny mine at Manhattan, Nevada.

GEORGE COPELAND is manager for the Caribou Gold Mining Co. at Bullion, British Columbia.

FRANK BAIRD is smelter superintendent for the Penn Copper Co. at Campo Seco, California.

C. J. GARVIN has resigned as manager for the Green Mountain M. Co. at Silverton, Colorado.

BEN TIBBEY, consulting engineer of the Mascot Copper Co., in Arizona, has returned to Salt Lake.

ROGER TAYLOR is superintendent of the copper reduction department of the Tacoma Smelting Company.

W. H. BLACKBURN, superintendent for the Tonopah Mining Co., of Tonopah, is in Denver for a few days.

HOWARD W. DU BOIS, of Philadelphia, was in San Francisco this week, on his way from British Columbia to Nevada.

E. P. JENNINGS, of Salt Lake, recently examined a property near Battle Mountain, Nevada, for a Salt Lake syndicate.

A. A. HASSAN has organized an exploration company for work in Ontario and Quebec, with offices at 250 Toronto St., Toronto.

J. GEARY has returned to San Francisco from the Round Mountain district of Nevada owing to the serious illness of his father.

W. J. WATSON is the superintendent of the Tye Copper Co.'s smelter at Ladysmith, Vancouver Island, British Columbia.

DONALD F. CAMPBELL is general manager of the mines and smelter of the Noble Electric Steel Co., in Shasta county, California.

THEO. L. LAMMERS has resigned as general manager for the Panhandle Smelting Co., and will take charge of mining operations in Montana and Idaho.

JOHN DERN, president of the Consolidated Mercur Gold Mines Co., of Utah, has been making an inspection of the Nevada-Douglas and other mines at Yerington, Nevada.

J. R. FINLAY, F. L. SIZER, W. H. WILEY, and H. V. WINCHELL are experts in the lawsuit pending between the Federal and Bunker Hill companies, at Wallace, Idaho.

G. CHESTER NOBLE and CHAS. S. DAVIDSON have opened offices in the Crocker Bdg., San Francisco, to engage in the practice of electrical, hydraulic, and power development engineering.

General Mining News.

ALASKA.

At Candle City, north of Nome, C. L. Morris has contracted to build one of the largest ditches in the Seward Peninsula, designed to supply all Candle with water. C. F. Ashford surveyed the course. The chief intake will be on Quartz creek, and it will also get the Hunter creek water. The length will be nearly 40 miles.—Miners are scarce in many parts of the Kaugarok. In Macklin gulch, the pay is \$7 per day and board.—The Port Clarence M. & D. Co. has been incorporated to work claims on Slide Mtn. that show sylvanite ore. Joseph Bartolis is president and Paul Krets treasurer.—Reports from Fairbanks state that the labor strike in the Tanana camp is practically over and the creeks are busy. Underground men receive \$6 and board per day of 10 hours, and top men \$5 for 8 hours. Latest news from the Innoko district says that a few claims are being worked, but enough prospecting has not yet been done to prove the camp. Work is being done on Gane creek and its tributaries, especially Ophir and the left fork.

The annual exodus of miners is at its height. All the boats from Alaska are crowded with miners from the coast and inland districts who are hurrying South to spend the winter. This rush will keep up until winter prevents further navigation.—The thefts of gold from the registered mail pouches still continue. It is said to be due to lack of proper guarding of the registered mail. Often the gold in the registered mail sacks, coming down on the river steamers from camps of the interior, amounts to several hundred thousand dollars, yet no guard is stationed over it. It is locked up in a stateroom and only occasional peeps at it from the purser by day and the watchman on the boat safeguard it at night.

ARIZONA.

COCHISE COUNTY.

While few men have been laid off at Tombstone, many of the miners have been taken from the stopes and put upon development.—Jack Kelly, who located the claims now owned by the Bisbee Extension Co., has discovered, near the old Black Jack mine last worked in 1883, a promising vein, carrying gold, silver, and copper.

GILA COUNTY.

The copper output of the Old Dominion Co. for September shows no decrease, being 3,577,000 lb. The various properties of the Superior & Boston are looking fine. The Gem shaft is 1,025 ft. deep, but still in country rock.

GRAHAM COUNTY.

(Special Correspondence).—The new furnace at the Shannon smelter at Clifton has been blown-in. The output for September was 1,500,000 lb., representing 15 days' run of the new furnace. Perry & Spence, whose mines are in the Carlisle district, 20 miles northeast of Clifton, will make regular shipments to the Shannon smelter. Several cars of ore have already been shipped from this mine. The ore is hauled by wagon to Duncan whence it is shipped to Clifton. Several other mines at Carlisle will soon be producing. Some rich silver ore has been struck on claims in the mountains west of Morenci. These claims were located by Frenchy Langermann; since then he has associated with him several outside parties.—The last six feet of the shaft at the Oregon mine, near Clifton, belonging to the Clifton Gold & Copper Co., is in ore. The shaft will be sunk to a depth of 100 ft. Patches of native copper found in the wall-rock indicates a similarity to the old Longfellow mine. This company has also begun to sink a shaft at their Santa Rita mine on the Coronado railroad, 12 miles from Clifton, where some assays as high as 4% copper have been obtained.

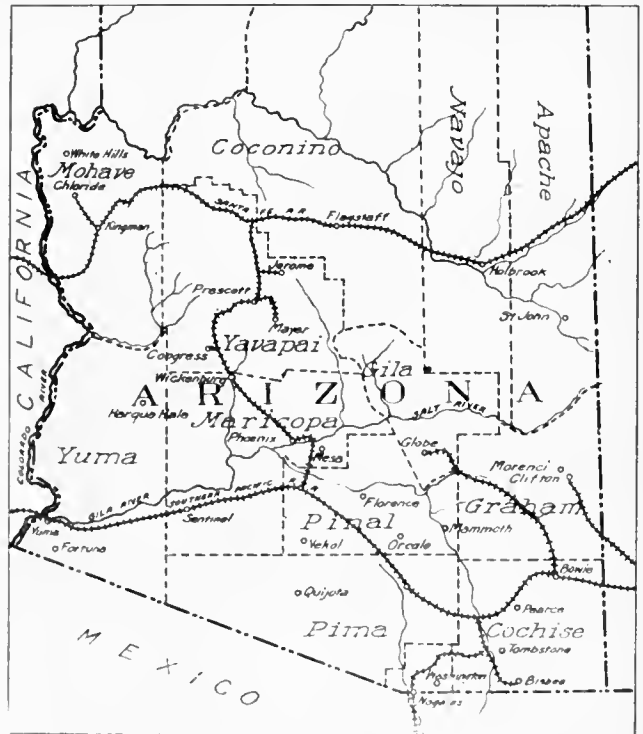

Phoenix, Oct. 8.

All the departments of the Detroit Copper Co. were closed down September 24 in respect to D. Willis James. Every camp of the Phelps-Dodge company, as far as possible, was shut down for the same reason.—The Clifton Gold & Silver Co. was recently organized to develop 22 claims near Morenci, which are surrounded by mines of both the Ar-

izona Copper and the Detroit Copper Co.—The New England & Clifton Co. intends to shut down its Copper King mine. The completion of the tramway to the Antietam mine of this company, has been greatly delayed by the cave which occurred some time ago in the Shannon tunnel.

PINAL COUNTY.

(Special Correspondence).—The Copper Creek Mining Co., operating about 14 miles east of Mammoth, has recently opened several large bodies of fine ore. The four most important workings show bodies of ore as follows: In the first, 7 ft. of rich copper glance at the 200-ft. level; in the second, 52 ft. of carbonate and oxide ore on the first level; in the third, 28 ft. carbonate ore on the first level, 37 ft. carbonate and oxide on the second level, and 45 ft. of good sulphide on the third level; the other working has 73 ft. of carbonate and oxide on the first level, and solid ore all the way down to where the second station will soon be cut. The company is receiving estimates on a 300-hp. central power-plant, and a smelter, which will be installed as fast as the work can be done. An electric surface tramway two

Map of Arizona.

miles long will be put in to handle ore from the mines to the smelter. A post-office, called Copper Creek, has been established at the company's camp.

Copper Creek, Oct. 7.

The old Reward copper mine, 30 miles south of Casa Grande, has been sold to a group of men including H. B. Hovland, L. C. Shattuck, H. A. Smith, S. R. Kauffman, and E. N. Breitung. Charles S. Morris will be the manager of the new organization, which is known as the Casa Grande Development Company.

YAVAPAI COUNTY.

The decline in the price of copper has not affected work in the Jerome district.—The settling of the United Verde smelter has stopped, and construction work on the new furnace is being rushed.—The long tunnel is in 1,550 ft., and when completed will be 7,200 ft. long. The United Verde company is rebuilding the Walnut Spring dam, the water to be conveyed to the smelter through two miles of 10-in. pipe. A 500,000-gal. oil-storage tank is completed at Jerome Junction.—Three shifts are sinking the Verde Grande shaft, and good progress is being made in the Boston Jerome shaft.—The Arkansas-Arizona shaft went down 78 ft. during last month.—Mac Willard has driven a tunnel 515 ft. in the Squaw Plad district, and has a south drift 150 ft. long from the 350-ft. point.—The old 265-ft. shaft of the Sycamore Copper Co. has been enlarged 165 ft. down; a

new road has been built to the power-house and shaft, and an engine installed to run the blower.—Another 80-hp. boiler has been ordered, and a station pump.—The long tunnel at the Eureka is progressing satisfactorily.

CALIFORNIA.

AMADOR COUNTY.

The south drift of the 3,000-ft. level of the Kennedy mine has cut the vein. The ore is three feet wide, but the vein-filling is over nine feet wide. This orebody south of the shaft is the most remarkable both as to size and character that has ever been found in this mine. It is continuous from the 2,400-ft. level to the 3,000-ft. level; in places it is 1,000 ft. long while it sometimes attains a width of 30 feet. While the bulk of the ore is of milling grade, still much bonanza ore occurs in it. The shaft at the Kennedy is to be sunk another 150 feet.

BUTTE COUNTY.

The Butte County Dredging Co. has purchased land on Butte creek, near Chico, on which they propose to install a dredge.

INYO COUNTY.

Considerable work has been done this year at the mines near Big Pine and most of them look quite encouraging. As the owners are not trying to sell their mines, little is heard about the camp.—Twenty miles east of Big Pine is the Eve copper mine, where 30 men are working. Schwab is supposed to be the real owner of this mine. The main shaft is 250 ft. deep and will be sunk to a depth of 400 ft. Developments indicate that the vein down to the 250-ft. level has a width of about 80 ft.—Further to the southeast is the lead prospect which was located four months ago by J. P. Fitting. The vein-filling is six feet wide with a streak 12 to 16 in. wide, rich in gold, silver, and lead.—Twelve miles down the valley from Big Pine is the Poverty Hill mine of the Buckeye company. The shaft is 159 ft. deep and the development indicates a wide vein of free-milling ore.

KERN COUNTY.

The well being sunk by the Yellow Aster Co. is 425 ft. deep at present and a large amount of water is flowing from it.

NEVADA COUNTY.

(Special Correspondence).—The Morning Star mine at Randolph Flat has been purchased by the Nevada County Midas Co. from James Bros. The new owners will sink a double-compartment shaft, and install a gasoline hoist and pump.—A rich shoot of ore has been struck near the 300-ft. level in the Kenosha. The Cornish pump has been installed on the 300-ft. level, and sinking on the shaft is about to commence. George W. Root is manager.—Another rich strike is reported from the California, the latest discovery being made about 20 ft. below the former pocket.—Good ore has been struck in the bottom of the 160-ft. shaft of the Gold Mound, and also in a drift at a depth of 105 ft. Some of the ore assays \$400 per ton. Howard Dennis is the superintendent.—Sinking has been resumed at the Central shaft and is progressing at the rate of 5 ft. per day. Rich ore is being taken from the 2,300 level in the North Star. Much development work is under way.—The North Star has declared the regular quarterly dividend of 20 cents per share.—Several good strikes are reported in the lower levels of the Empire, with excellent ore being taken from various points.—Operations are about to be resumed at the Sunflower, after a period of inactivity.—Several drifts are being run at the Conlan to strike the vein.—Good ore continues to come from the lower level of the Brunswick. The lode is improving with depth, and the average is excellent.—A shaft is being sunk on the Gambrinus vein, near the Gaston mine.—It is reported that the Gaston will resume operations at an early date.—The vein recently encountered in the lower levels of the Murehie is showing up well, and some rich ore is being extracted.—Good ore is being taken from the lower levels in the Champion, where much development is being carried on. The mill is running constantly on ore running from \$20 to \$50 per ton.—It is reported that the Gold Flat will resume before the end of October.

—Good ore continues to come from the California copper mine near Spenceville. The tunnel has opened up a large body of sulphide ore.—Local stockholders in the New York-Grass Valley have decided to oppose the action of the management, which provides for the transfer of the mine to a new company to liquidate indebtedness, with the provision that if the amount is not paid within one year, the property will pass completely to the new organization. The local people demand that the period for payment be increased to three years, and will bitterly contest a shorter period.

Grass Valley, Oct. 7.

The Morning Star property at Randolph Flat, two and a half miles west of Grass Valley, recently passed into the hands of the Nevada County Midas Mining Co., which is mainly composed of local people.

At the Gold Mound mine at Deadman's Flat, rich ore has been struck in a drift at the 105-ft. level. A few days later still richer ore was struck in the shaft at a depth of 160 ft. The ore carries galena and metallic gold and is seven feet wide. The Gold Mound mine is in new ground some distance west of the older mines. Last week rich ore was also struck in the California mine at Deadman's Flat but, as the California mine is one of the older mines of the camp, this strike is not so important to the camp in general as that at the Gold Mound.—The developments during the last few weeks at the Austin mine, in Willow Valley district, have been very satisfactory. High-grade ore has been found in the north drift where a 14-in. vein has been found. As this vein was only from 4 to 8 in. wide where developed nearer surface, the owners are greatly encouraged. In the south drift of the 400-ft. level a strong vein 2½ ft. wide of good milling ore is being developed.

PLACER COUNTY.

(Special Correspondence).—The Placer Gravel Mining Co. at Last Chance is running a cross-cut and raise from the old El Dorado tunnel to catch the lower end of the Big Lead channel, which they cut some time ago, in a raise some 1,800 ft. upstream from their former workings. The new cross-cut leaves the old El Dorado tunnel near where the Sharp Stick channel was discovered. At the upper end of the Big Lead the gravel pays well, but as they are working downstream mining is proceeding at a disadvantage. Dave Ray, the superintendent at the mine, has 14 men at work. This mine is about 1,700 ft. above where the north fork joins the middle fork of American river, and has a good dump. The gravel at the mine is fairly free from cement, but as a precaution Mr. Ray has arranged a series of drops in the sluices and consequently the loss in the tailing is quite low. As yet no rare minerals have been found in the black sand from this gravel.—At the Rubelin group, a quartz property in Last Chance ravine, about one mile below the town, the drift on the lode is in about 40 ft. The vein has an 18-in. streak of ribboned quartz which assays \$10 per ton. The ore carries some galena and pyrite with scattered specks of free gold. It is intended to install a 2-stamp mill soon. This drift on the vein will give a good back of ore. The vein is said to have been traced for over two miles.—At the Home Ticket drift mine on the same channel as the Placer Gravel company 12 men are blocking out the gravel. The gravel in this mine is cemented and so will require crushing.—The Deadwood Drift property is not working at present owing to the litigation on account of which it has been shut down for several years. The Hazzard drift mine on the Turkey Hill channel is also shut down for the same cause.—George Wingfield has failed to make the payment on the Queen mine which recently became due. The owners, Savage & Warden, will work it themselves.—At the Herman mine, where the old 10-stamp mill has been started, but owing mainly to the distance of the mine from the railroad, trouble is being had in getting miners.

East Auburn, Oct. 9.

Much prospecting has been done on the Upper Forest Hill Divide this season. Several quartz veins have been discovered and the developments are quite encouraging.—It is reported that the upper 'lead' has been discovered

at the El Dorado gravel mine at Last Chance. The lower pay has been worked for 4,000 ft. along the channel. After long prospecting the upper pay was discovered in a raise 1,600 ft. from the mouth of the tunnel.

Reports have reached here from Australia concerning Francis P. Bray, who was well known in local mining circles. According to these reports, he has made a good record for himself in managing the Peters' Gully mine at South Heathcote, Victoria.

SHASTA COUNTY.

The Noble Electric Steel Co. has let a contract for the first unit of a battery of 12 charcoal furnaces. The by-products will be saved and the proceeds from their sale will materially decrease the cost of the charcoal to the company. The sample consignment to the Union Iron Works of electrically smelted pig iron made at Heroult was pronounced the finest pig iron ever received by that company.

SIERRA COUNTY.

The well-known Keystone mine near Sierra City, where the buildings were swept away last winter by a snowslide, has been leased to several miners who formerly worked at the mine. They intend to repair the 10-stamp mill and

the quartz belt that runs through the China gulch basin. Osgood & Wintering are the owners of the property.—Milton Dunphy and Roy Vincent are developing the White Swan and neighboring claims near Sawyers Bar. They have opened a vein of free-milling ore that promises well.—E. H. Scott has bonded the Corson & Kradle and the Gardner properties at Oro Fino. The ore is of good grade but requires cyaniding.—At the Home group of mines near Sisson a copper vein is being prospected in the north drift of tunnel No. 3, while in the west cross-cut the blue-quartz vein has not been reached as yet.

TUOLUMNE COUNTY.

The Spring Gulch mine will resume work this week but, owing to the supply of wood being small, only a few men will be employed until the power line from the Tuolumne Electric Co. plant can be stretched. This will be completed within 90 days. A new mill is to be erected at the mine and a cross-cut is being started on the 600-ft. level to catch the rich ore-shoot recently found on the 300-ft. level.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—A 2-ft. vein of smelting ore

running 20% copper, and \$5 in gold and silver, has been struck 700 ft. from the entrance of the fifth level in the Santiago. The drift will be run 100 ft. farther, at which point stopping will commence. An aerial tramway is being built from the fifth level to a point above the Wilcox tunnel to facilitate the shipment of ore.

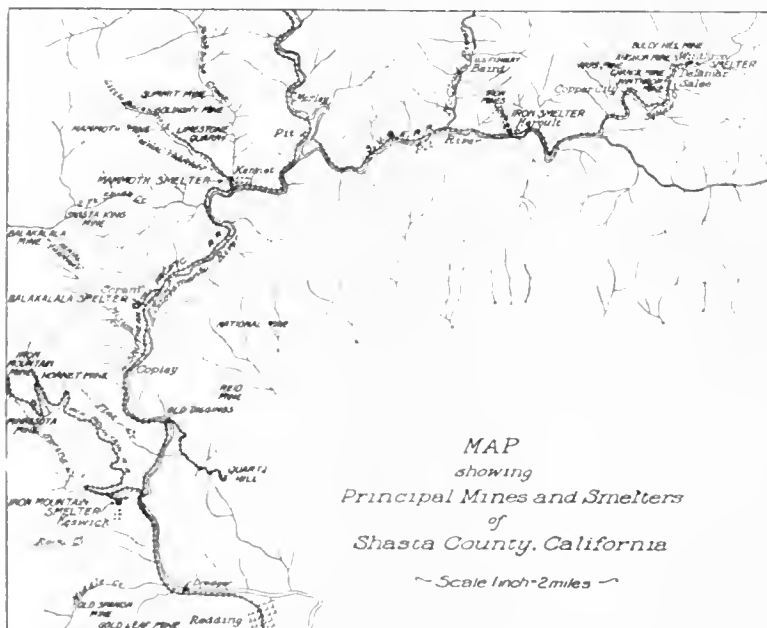

The Maud S. mine on Douglas Mtn. is making heavy shipments of ore running 70 oz. silver per ton.—The Beyers lease on the Zero tunnel is shipping silver-lead ore running \$100 per ton. A 9-in. vein is being developed.—A rich vein of silver-bearing ore has been struck in a blind drift on the Aster. The streak is 11 in. wide, and runs 3,000 oz. silver per ton. A 3-ft. body of ore running 330 oz. silver is being developed. The mine is worked under a lease by Butts & Co.—A rich vein of silver ore 16 in. wide is being developed on the Seven-Thirty through the Hercules tunnel.—Work has started on the 100-ton mill of the Capital Co.—The Boston mine is shipping 30 tons per week to the smelter. A 3-ft. vein carrying silver and lead is being developed in the upper

workings.—A 9-ft. lode running \$50 per ton in gold and silver has been struck in the Collin mine on Young Mtn. in the Atlantic district. The strike was made 175 ft. from the portal of the adit. The shoot has been opened for 60 ft.—A 4-ft. vein rich in lead has been struck in the east drift on the Flossie vein, in the Vidler tunnel.—At several points in the Tobin mine, silver telluride has been encountered. Eight leases are operating on the mine in good ore. Shipments are being made to the Denver smelters.—An 8-in. streak of silver-lead ore running \$50 per ton has been struck in the Mendham mine in East Argentine. W. S. Graves is operating the property under lease.—The new mill of the Ramsdell Co. is completed, and will soon be running.—The Honest John tunnel will be driven several hundred feet, with the expectation of cutting several veins and opening up virgin territory. On the Delaware lode, recently intersected by the tunnel, much development is under way.—A body of smelting ore has been struck in the east drift on the Aetna vein.

Georgetown, Oct. 3.

OURAY COUNTY.

(Special Correspondence).—Walter Bunce, manager for the Chipeta Tunnel Co., started work about one year ago in his tunnel to find the American Nettie ore-shoot. A few days ago he encountered what he believes to be it, beyond the fault. How the ore turns out remains to be seen, although the strike is of considerable importance. The tunnel which he started one year ago is 8 by 8 ft., and over

begin to mine as soon as possible. The mine was paying well when the snowslide occurred; a good pay-shoot is in sight.

Arrangements have been made to push development on the property owned by the Sierra Gold & Copper Mining Co. at Purdy's station. There are four or five parallel veins in this group of claims, all of which show up well at surface. Rich ore has been found in several claims in the district and the camp as a whole is looking well. Prospecting, which has been done this summer between the Purdy and Loyalton districts, indicates that the latter is the eastern extension of the Loyalton mineral zone.

SISKIYOU COUNTY.

The Humboldt Siskiyou Mining Co. was recently organized to operate a prominent group of quartz claims near Callahan. The main vein is about 3 ft. wide, with numerous rich stringers. Development has exposed much good ore near the surface. A 10-stamp mill has been ordered and the site is being graded. H. Hersey is superintendent.—Rich ore has been found in the lower level of the Ten Lakes copper mine near Edgewood, which is operated by the Osborne brothers. The lode is several feet wide and in places is quite rich. Considerable development work is being done and several of the veins have been stripped for quite a distance. The latest strike is said to be the most important discovery made in the mine.—The quartz ore recently found on the ridge between South Russian and Apple Sauce gulches, in Liberty district, appears to be a continuation of

2,500 ft. long. The first 2,000 ft. was made in six months. An average of 341 ft. was made for five consecutive months, which it is believed to be as rapid work as has ever been done in Colorado. Two shifts were employed to do the work. No timbering was necessary, except at the portal. Ingersoll drills are used. Only one angle has been made, and that on account of ownership territory, and this angle was 1,500 ft. from the portal.—One mile from town, the Mineral Farm is producing about 60 tons of concentrate per month with 10 stamps. Another 10 stamps is being put in order, and B. H. Du Praw, the superintendent, hopes to increase the shipments to 120 tons inside of 60 days. The adit is 300 ft. long, and a shaft from the adit level is down 180 ft. Ore is coming from the shaft, and some crude ore is shipped to the smelters. Temple-Ingersoll drills are used for driving and development work, and Sinclair and Waugh drills for stoping. Electric power is used in the mill and mine. On account of the scarcity of water they are obliged to pump it up and use it over again.—The Thistledown M. & M. Co. is operating one shift while waiting for the compressor and drills which will be installed in the next 30 to 60 days. A 3,000-ft. adit has been run and an 800-ft. raise is being made to the ore opened in the upper workings. About 200 ft. has already been made in the raise, and when machinery is installed work will be pushed as rapidly as possible. It is understood a mill will be erected below the adit level when more development work has been done. M. L. Thistle is manager.—Some of the operators in the district report a scarcity of good hammermen, but machine men are plentiful. A number of men have recently come in from Butte and other copper camps, which has materially changed the situation here regarding shortage of miners.

• Ouray, Oct. 5.

SAN MIGUEL COUNTY.

(Special Correspondence).—Some time ago the Pandora Co. began to work the lease which they had secured from the Smuggler-Union Co. on the Pandora vein in Smuggler ground. They are taking out 80 tons per day, which is sent to the Pennsylvania tunnel, where it is transferred from the Jigback tramway to the Smuggler tram and sent to the old Smuggler mill at Pandora. There it goes to the 20 stamps that the company leased. The first-class concentrate averages \$175 and the second grade \$125 per ton. The saving from the plates and Pierce amalgamators pays all running expenses of mine and mill. The company is mining some shipping ore which averages $3\frac{3}{4}$ oz. gold and 160 oz. silver. Two per cent monthly dividends are being paid. The company also has a bond on adjoining property, which they will undoubtedly take up if they are unable to get the lease extended when it expires next July. Thirty men are employed on the property. The company has leased the old Valley View boarding-house which adjoins the Pandora property. W. F. Smith is manager.

Telluride, Oct. 2.

TELLER COUNTY.

Good progress is reported by William Bainbridge, the superintendent for the tunnel company in sinking the intermediate shaft. This is to be sunk to a depth of 1,000 ft.—The large Crane washer at the Cresson was started last week, when the mine resumed operations.—A new body of ore is reported to have been found at a depth of 145 ft. in the Lucky Corner claim on Gold hill. It is also reported that a four-inch seam of rich ore has been struck on the 800-ft. level of the Granite property on Battle Mtn.—It is reported that the ore below the 1,000-ft. level of the No. 2 shaft of the Portland company is fully as rich, if not richer, than the ore above. The No. 2 shaft is now 1,265 ft. deep, and will be sunk to 1,500 ft. where a station is to be cut.—The Portland company has declared a \$120,000 dividend, payable Oct. 15.

IDAHO.

ELMORE COUNTY.

The Atlanta mining district, 80 miles from Mountain Home, is the scene of considerable mining activity. The Franklin mine and mill at Pine are producing, under the charge of C. L. Hopkins. The property is owned by R. P.

Chattin. The Atlanta mines, comprising the Buffalo, Last Chance, and Monarch, are owned by T. N. Barnsdall, of Pittsburg. Dan Kirby is in charge, and in five years, 10,000 ft. of work has been done, including a 625-ft. vertical shaft, and a 900-ft. drift on the 600 level. The Last Chance mine is on a different vein, and is connected with the mill by a $1\frac{1}{4}$ -mile Bleichert tram. The new mill, which will have a capacity of 150 tons per day, will treat ore by amalgamation, concentration, and cyanidation, and was designed by F. W. Sherman, of Salt Lake. Water power, applied to two De Reymer wheels, will operate the mill, and a 100-hp. electric motor has been installed. W. E. Gracey is the mine superintendent.—The Petit group covers a continuation of the Monarch lode, and belongs to the Bagdad-Chase company, of California, for which Wayne Darlington is the manager. A good deal of ground has been opened and a 20-stamp mill is being erected, the ore to come over a half-mile aerial tramway. A power-plant is being built two miles from the mill. C. S. Stevens is mine superintendent.—The Tahoma mine, in Quartz gulch, is owned by C. W. Miller, of Pennsylvania. It has been idle for years, but will be worked again. Drifts aggregating a mile in length are open, and an old 10-stamp mill is standing.—In the Minerva mine, 3,000 ft. of workings stand open, and a 10-stamp mill is running steadily, being operated by steam-power. W. F. Oden is superintendent, and Ogden Brown manager.—The Big Lode and Jessie Benton, both having mills, and situated in Quartz gulch, are idle.—Across the river from Atlanta, the Bonanza M. & I. Co. is operating a placer property, in charge of L. N. Franke. There is a 750-ft. bedrock sluice, and two giants are working on 15c. ground.

SHOSHONE COUNTY.

(Special Correspondence).—News comes of a strike of a shoot of galena on the 2,200-ft. level of the Tiger-Poorman mine at Burke, which was closed by the Federal M. & S. Co. several weeks ago, and the breaking into of a wide vein of silver-lead ore on the 900-ft. level of the Hecla mine, across the gulch from the Tiger-Poorman. Reports from Burke are that the bottom of the shaft of the Poorman mine is in ore and that it is purposed sinking it 200 ft. A large force of men is at work in the mine.—Arrangements have been made with the management of the old Bull Pen mine, known as the Independence property, adjoining the Copper King, Missoula Copper, and National Copper properties, whereby the 1,000-ft. tunnel driven and abandoned by that company, has been leased to owners of the Missoula Copper Co. to drive an extension 600 ft., cutting the Missoula Copper Co.'s orebody at a vertical depth of 800 ft., or 500 ft. below the present workings. The concern has a capitalization of \$1,500,000. A compressor will be installed on the Missoula ground, and 150 ft. per month will be driven with the new equipment. Several stringers of copper have been cut and reports are that the orebody has been encountered at depth, and some ore in the cross-cut averages 4% copper, while stringers have been found that assay higher.—Reports issued by W. D. Greenough, manager of the Snowstorm Mining Co. at Mullan, show the net earnings of the mine for the fiscal year were \$498,013. Dividends paid to stockholders amounted to \$359,910, leaving a surplus in the treasury for the year of \$91,625. Estimates of the value of ore in transit is \$135,055. During the year the mine produced 87,503 tons of ore, of which 77,782 tons were shipped directly to the smelters and 9,721 tons milled at the mine. Extensive improvements, including a tramway of 5,800 ft., connecting No. 3 tunnel with the railroad, and compressor, power, and lighting plants have been installed. To meet the growing needs of the mine an additional 300-hp. compressor and motor have been ordered.—Stockholders of the Senator Stewart Mining Co. at the annual meeting at Kellogg, elected these directors: C. R. Leonard, N. W. Bacon, Butte; E. J. Carter, Spokane; B. F. O'Neil, Wallace, and Stanley Gifford, New York. Leonard and Bacon are president and secretary. The Senator Stewart is two miles from Wardner. Regular shipments will begin as soon as a railroad spur to the property is completed.—The 124th consecutive monthly dividend of \$180,000 by the Bunker Hill & Sullivan mine has been declared. The payment

brings the amount paid to stockholders since January 1, 1907, to \$1,620,000, and the total dividend paid to date \$9,486,000. The Snowstorm Mining Co. has also declared its monthly dividend of three cents per share, or \$45,000. This brings the total for the year to \$360,000, and the total to date to \$450,000, the company having paid a \$90,000 dividend a year ago.

Spokane, Oct. 4.

WASHINGTON COUNTY.

Considerable interest is being shown in the kaolin deposit recently discovered eight miles from Idaho Falls. The deposit is said to be eight feet wide and can be traced for over a mile. The kaolin is said to be quite free from grit. Tests of its pottery properties are being made.

NEVADA.

CHURCHILL COUNTY.

(Special Correspondence).—Fifteen lessees are working in the new camp of Rawhide, 45 miles south of Fallon and 40 miles east of Schurtz, and ore running as high as \$8,300 per ton has been taken out. Another lessee has an 8-ft. vein which pans gold, and a 12-in. streak which assays \$238. The mineral belt is at least five miles long by three wide and the formation is very similar to that of Goldfield, the general character being eruptive rocks, principally rhyolite, andesite, dacite, and porphyry, often capped by a Malapai of later origin. About five miles to the north is a belt of stratified rocks, including schist, slate, and limestone. A townsite has been formed and between 200 and 300 prospectors are at present here, and a number of business places.

Rawhide, Oct. 7.

(Special Correspondence).—The Eagle's Nest property has been the scene of another wonderful strike, a good body of \$400 ore having been opened in the drift from the 100-ft. level.—The strike was made by the Eagle's Nest Mining & Leasing Co., locally known as the Davis lease. Work was started less than a month ago, and owing to well-advised development rich ore was struck almost immediately. Sacks have been ordered and will soon be on the ground. A complete hoisting plant, purchased in Fairview, will be installed.—This strike has demonstrated the continuity of the rich Fairview Eagle vein; consequently leases on the Eagle's Nest and the Hailstone properties are urgently sought. The outcrop is traceable into Hailstone ground, and with proper development, the rich silver sulphide ore should be opened there also.—This part of the Fairview district is coming to the front, as the Nevada Hills, Eagle, Eagle's Nest, Dromedary Hump, and Golden Boulder are in rich ore, and are sacking it for shipment.—The Nevada Hills is the pride of the camp. It is estimated that over \$5,000,000 of ore is now blocked out in the different workings. Most of this is of a shipping grade. About 50 men are employed in the Nevada Hills, and more are added as fast as places can be made for them. The new railroad, arrangements for which are practically completed, will be built right up to the loading station.—The Jarvis lease on the Fairview Eagle is daily sacking ore, some of which will assay \$1,000 per ton, while the main company workings are being opened to good advantage.—The producing area of the Fairview district is fast expanding, and rich ore has been found for a distance of about seven or eight miles. At the extreme northern end of the district, and out in the flat, is the Hot Onion group. High-grade ore has been found on this property, and shipments are regularly being made, while fully seven miles to the south of the Hot Onion some high-grade ore has been found on the Gold Crown, the Nevada Fairview, and the Nevada Condors properties.—The camp generally is picking up rapidly. The railroad from Fallon, the electric lighting and trolley system are in prospect, and preparations are being made for an active fall and winter.

Fairview, Oct. 8.

HUMBOLDT COUNTY.

(Special Correspondence).—The Brown Palace is developing into one of the richest properties in this county, and the mine is a steady shipper. It is said that the ore assays well in gold and silver.—The main shaft at the Dream-

land is down 100 ft. and some ore is being developed. Shipments will be deferred until the Western Pacific railroad reaches this property.—Several shafts and tunnels are being driven to develop the orebodies in the Golden Triangle, but no shipments will be made until the railroad is completed.—A vein is being developed in the Big Six, and the shaft is going down rapidly.—A 20-ft. low-grade vein has been struck in the main tunnel of the Springfield. The strike was made near the surface.—Some ore is being opened in the shaft at the Durango Girl. The shaft is going down, with driving on the vein.—It is said that a rich strike has been made at a depth of 400 ft. in the Seven Troughs.—A strike is reported from the Fairview.—A body of sulphide ore has been struck in the 212-ft. level in the Buckhorn, so the shaft will be sunk deeper.—Excellent ore is being taken from the vein in the Kindergarten, and the mine is showing up well. Development is under way and a reserve of milling ore is being blocked out. Some shipping ore has been sacked.—Another strike is reported to have been made in the main shaft of the Mazuma Hills.

Rosebud, Oct. 7.

NYE COUNTY.

The Shoshone mill, though running continuously, is working two shifts, but this week three shifts have been put on at the Tramp mill. Good shipping ore is being mined in the south drift on the 200-ft. level on the Tramp vein, where three shifts of miners are being worked. The smelter returns from a 23-ton shipment of high-grade ore from the National Bank mine gives an average of \$485 per ton. The underground development is quite encouraging as considerable good milling ore is being found. The company intends to equip the mine with 2½-in. Ingersoll-Sergeant drills. The Mayflower mine is showing up well on the 400-ft. level. It is announced that the Clark road will be completed to Goldfield by the middle of the month.

OREGON.

JOSEPHINE COUNTY.

The Rogue River M. & D. Co. is preparing to put in a long flume for the winter's run on its placer property on the Rogue river, at Blossom Bar, Paradise Bar, and Little Tommie East creeks. Edwin J. Porteous is the superintendent.—A good winter's run is expected at the placer property of the Swastika Mining Co., of which A. C. Howland is the manager.

WASHINGTON.

SHOSHONE COUNTY.

(Special Correspondence).—The case of Jonathan Bourne, Jr., owner of the Ontario mine, v. the Sierra Nevada Mining Co., was heard by Judge Wood of the District Court at Wallace last week. The case involved a question of extralateral rights. The hearing attracted much interest, as it appeared to be virtually a controversy between the Bunker Hill & Sullivan Mining & Concentrating Co. on behalf of the plaintiff and the Federal Mining & Smelting Co. on the side of the defendant. The interest was further intensified by the prominence of those who gave expert testimony, among whom were F. L. Sizer and W. F. Word of Helena, H. V. Winchell of St. Paul, W. H. Wiley of Los Angeles, J. R. Finlay of New York, and N. E. Linsley of Spokane. A mine model was produced in court, as well as elaborate maps, to make plain the surface boundaries, the extent of the workings, and the position of the orebodies. Stanly A. Easton, manager for the Bunker Hill Co., and W. Clayton Miller, manager for the Federal Co., were in attendance.—Considerable development has been done this year at the Stanley mine, which is near the Hercules mine at Burke. On the lower levels high-grade stibnite has been found. The ore is quite clean and also carries some silver and gold. Parties from Galena, Ill., have been examining this mine, and three carloads of the stibnite have been shipped to that point. It is claimed that the ore carries as high as 70% antimony. The property is being developed by the owners, among them being M. J. Farrell, H. J. Rossi of Wallace, and W. W. Merk of Spokane.

Wallace, Oct. 7.

Special Correspondence.

Denver, Colorado.

Tunnels or Adits.—The Daily Press and Gas.—General Mining Activity. — Humor in Journalism, Especially at Colorado Springs.

Possibly the squeeze in stocks has attracted attention to the water question. Certainly tunnels have evoked an unusual amount of interest lately. At Idaho Springs a contract has just been let to drive an adit 4,000 ft. from the mouth of Trail creek to unwater the workings of the Metropolitan, which has so far labored under unfavorable drainage conditions. The Honest John Co., at Georgetown, also announced its intention to extend their adit to a distance not yet determined. At Red Mountain the Joker tunnel has passed through the Guston and Yankee Girl workings and will soon reach the orebodies exposed in the Genesee workings. At Telluride it is reported that work on the Meldrum tunnel will soon be resumed, as negotiations with a syndicate for the prosecution of the work are well advanced. This last is a most ambitious undertaking, the attempt being to pierce directly through the divide from the head of the San Miguel to the Red Mountain side. The adit is being driven from both sides and has penetrated about 4,000 ft. of the total distance. In the course of the work some exceptionally promising veins have been cut, but no exploratory work on them has so far been done.

The daily press has found opportunity for the publication of a lot of rubbish following the incident of last week when several miners were temporarily imprisoned in some workings tributary to the Ophelia tunnel by an unusual development of the 'bad air,' so familiar to those operating in the Cripple Creek district. As is well known to all mining men, the rather porous rock of the crater is full of gases that appear like the last exhalations of the Cripple Creek volcano. These consist chiefly of nitrogen and at times, when the barometer is low on the surface, and the atmospheric pressure is correspondingly diminished, the gas comes pouring out of the wall-rock and frequently so fills the working places as to absolutely prevent entrance for the time being. The appearance and disappearance of the gas is most generally abrupt and frequently exhibits no visible connection with any apparent cause. The simple facts of the incident were that 23 miners, when at the end of their shift, descended from their working places to the adit-level, found the adit filled with gas that barred egress. They simply returned to the working places and waited until a rope could be let down an unused shaft so that they could be drawn up by a windlass, as waiting for the gas to disappear might involve too long a period for hungry men. This simple incident was magnified by the irresponsible journals that seem to find the bracing atmosphere of Colorado particularly suited to their development, into an exposure to deadly peril and a thrilling rescue. Seriously, however, the gas forms little more than an inconvenience to working in most of the few mines that are subject to it.

Development work throughout the State continues encouragingly active. At Young Mtn., near Georgetown, the recent find of petzite in the Tobin mine has caused not a little excitement, while the opening up of a good body of galena in the Boston mine on Democrat Mtn. promises to be no less remunerative, though it does not stimulate so much interest. Near Salida, an organized attempt is being made to develop the copper deposits on Cottonwood creek, which have been irregularly exploited from time to time. At White Pine, production is

active and several transfers have taken place that promise to stimulate it even further. At Breckenridge, the Senator mill has begun operations, while at Silverton work continues active in spite of the slight damper put on operations by the closing down of the local smelters of the Ross Mining & Milling Company.

Few towns of 35,000 inhabitants possess a comic paper that is genuinely funny. Colorado Springs has the unique distinction in a paper called the *Mining Investor*. In its editorial columns it has patronizingly attempted from time to time to point out the errors and shortcomings of the journalistic activities of such periodicals as the *MINING AND SCIENTIFIC PRESS* and *The Engineering and Mining Journal*, as seen from its standpoint. In a more recent issue it proceeds to demolish (as it fancies) *Collier's Weekly* for a series of articles relating to the adventures of an investor with little cash and less wisdom who attempted to acquire much cash, but gained wisdom instead. To any rational thinker the series of

A Part of Colorado.

articles appear to be eminently illuminating to a group of people whose participation in mining speculation is far from desirable. To the strabismic vision of the *Mining Investor* it appears an attack on the legitimacy of the mining industry. With rare and unparalleled humor it follows its remarks on the subject with a full-page advertisement of an enterprise the chief assets of which consist of an excellent press agent and unlimited audacity; follows it by a half-page of another that is offering shares by the million at 10c. each with the assurance that they will go to 25c. by the end of the year; and most appropriately concludes its remarks by a tail-piece consisting of the advertisement of a similar periodical where with each year's subscription at \$1 one may secure 50 shares of the Bootlace (or something like that) Mining Co. with the full assurance that they will pay a dividend soon. When to stimulating the activities of a moribund mining stock exchange and to painting 10-ft. prospect holes into a glittering blaze of glory equal to that of a dividend-payer, are added a general oversight of national journalism, the ambitious individual is apt to find himself in the case of the drunken man in the bar-room who successively challenged to fight any man in the room, in the

county, and in the State; and regretfully concluded a few minutes later that he had attempted to cover too much territory.

Mexico City.

Progress at Guanajuato.—The Porfirio Diaz Tunnel.—The MacDonalds.—George Bryant and His Useful Work.—The Pinguico.

The message of Governor Obregon to the legislature of the State of Guanajuato at its opening session recently was a noteworthy communication in calling general attention to the remarkable progress at Guanajuato during the last few years. The Governor stated that the large companies now operating in the camp represented a capital of over P50,000,000, the greater part of which had been expended in equipment and development work; that these companies now had a weekly payroll of

the regeneration of this famous old camp of Guanajuato. Now the Sirena, after spending some \$200,000 in development work, is producing 300 tons per day, the mine and mill being in charge of still another brother, Joseph MacDonald. The MacDonalds also have charge of operations at El Carmen, located by M. E. MacDonald, and the first to attract special interest to the cross-veins of the Mother Lode, Los Cordones near El Cedro, and La Barragona near El Monte de San Nicolas. Next to the MacDonalds, the present prominence of Guanajuato is perhaps due, more than to any other one man, to George W. Bryant of the Guanajuato Development Co. The beginning of his success dates from the time, just six years ago, when he first interested Frank G. Peck and Colorado Springs capital in his Guanajuato schemes and got work started at the Peregrina, which is now a steady

Map of Mexico.

P150,000; and that all people in the city could banish fear in the knowledge that the great Porfirio Diaz tunnel would probably be completed by the last of January next, or at least before the coming of the next rainy season. Only those who have watched the progress of Guanajuato during the short years of this present century and seen the death and destruction wrought by the two most recent floods in these last five years can know what these things mean. The Porfirio Diaz tunnel will catch the waters of the rainy season well up the gulch in which the city of Guanajuato lies, and lead the devastating flood around and past the city to the valley below, assuring the future safety of the community. Six years ago the only property in this old silver camp that was producing a sufficient quantity of ore to be worthy of consideration was the Sirena of the Guanajuato Consolidated Mining & Milling Co., which with a small battery of 20 stamps and amalgamating pans was making a very creditable showing under the management of M. E. MacDonald. But not fully satisfied with the results of amalgamation, experiments were even then being carried on with cyanidation, and these were finally worked up to a successful issue by Bernard MacDonald, a brother of the former, and to his work with the cyanide process is due

producer. He has never been able to interest sufficient capital in his dredge scheme in the Guanajuato river to carry it through, and the enterprise has now been indefinitely laid aside. After getting the Peregrina started, Mr. Bryant got options on the Valenciana, Cata, Rayas, and Mellado, the most famous old properties on the Mother Lode and turned them over to the Guanajuato Reduction & Mines Co., which has 160 stamps dropping and promises soon to double that number; is unwatering the old mines comprising practically all the old and ancient workings of Guanajuato, and in addition to the ore from the upper portion of these workings, is treating 500 tons per day from the old dumps, which are variously estimated to contain from one to three million tons on the old Valenciana and another one or two millions on the Rayas and Mellado. Mr. Bryant then took up the Nayal, several miles southeast from Guanajuato, which some years before had been abandoned by Dwight Furness because of the vein pinching and the work being no longer profitable under the methods then in vogue, but Mr. Bryant's lamp seemed to respond to the rubbing and the Nayal is on his producing list. About this time Mr. Bryant organized the Guanajuato Development Co. and started work on the Pinguico, which is situated on

the same cross-vein as El Carmen and the phenomenal richness of the orebodies found therein have been heralded throughout the Republic. It has been as the crowning jewel to this man's work for and faith in Guanajuato. The mill for the treatment of the ores—a model of its kind—is just about completed. The mill consists of two units (a crusher, 20 stamps, and Chilean mill) of 100 tons each; an aerial tram runs from the mine, half a mile away, to the crushers (9 by 15 in.), a drop of 90 ft., thence to the stamps, each weighing 1,000 lb. and dropping 5 in. with 100 blows per minute; the coarser than 30-mesh goes to the Chilean mills and then all to Wilfley tables, whence the tailing goes to the cyanide vats. Assays in both the Pinguico and Carmen have shown almost conclusively that gold may be looked for in the cross-veins in the Guanajuato district in distinction from the ores in the Veta Madre wherein silver predominates. The Pinguico mill is completely equipped with electric power furnished by the Guanajuato Light & Power Company.

Butte, Montana.

Decrease in Production.—Question of Lower Wages.—The Barnes-King Fiasco.—John Gillie's Report.—A Wretched Affair.—Other Poor Schemes.—Work Stopped at the Stewart.

Officials of the companies concerned say that during the past week the curtailment of production by the Amalgamated, North Butte, and Butte Coalition companies reached about 75% of the normal; in other words, the output has been just a fourth of what it was last June. The reduction in the number of men employed has been corresponding, and instead of 10,500 miners there have been working during the past week not to exceed 2,500 men in the Butte mines. The companies are still mining the same grade of ore that was taken out before the orders for a curtailment were given, and, due to that and the reduced production, the cost of operating has been considerably advanced, some estimates placing the cost at 14c. per lb. It seems unlikely that such a condition can be continued very long, and it is anticipated that unless there is a speedy and material improvement in the metal market an entire suspension of operations in the Butte district will be ordered.

No action has yet been taken by the mining companies looking toward a reduction of wages of miners, although according to the terms of the contracts entered into some months ago the men are due to return to the old scale of \$3.50 per day. They were granted \$4 per day under an agreement that the old scale should be resumed if the price of copper should fall below 18 cents per pound and remain below it for 30 days. The companies have not yet taken advantage of the contracts, but have sent written notices to the Miners' Union that in view of the unsettled condition of the copper market the companies would not reduce the wages at the present time. It is understood that these notices were sent so that the companies would not waive their legal rights under the contracts by failure to enforce them. Similar notices were sent by the Amalgamated companies, North Butte, Butte Coalition, and the W. A. Clark company.

The Barnes-King Development Co. fiasco, the character of which has been disclosed by a report made to stockholders by John Gillie and the new board of directors, is really the first actual wild cat and mining fraud that has come out of the scores of new concerns that have been organized for operation in Montana. After an exhaustive examination of the mines of the company in Fergus county the president, John Gillie, and the vice-president, C. W. Goodale, find that the company has probably \$50,000 worth of ore in sight, for which the

stockholders paid \$2,000,000, the amount of the company's capitalization, and even that body of ore has been found since the new company took over the property, so that in the opinion of the new officers the property practically had no value when it was capitalized for \$2,000,000. It is stated that the experts who examined the property for the promoters were Will Word, of Helena, formerly an Amalgamated engineer; Walter Harvey Weed, formerly connected with the Geological Survey, and R. B. Lamb, a mining engineer well known in the West. The Word report was especially flattering to the property, as it accounted for a vast tonnage in sight, figured out tremendous values and profits, and extremely low cost of mining and milling. What was contained in the Weed report is not known as it was never made public in its entirety, and Mr. Gillie has been unable to get possession of the original. Only extracts from the Weed report have been given out, and they are very favorable to the property. John C. Lalor, manager of the Marcus Daly estate, and one of the promoters, was elected first president of the new company and he continued to give out the most glowingly optimistic reports of progress and wealth of the mine, coupled with promises of early and continuous dividends. R. B. Lamb was retained as general manager of the mine, and operations were directed by Superintendent Brule. Very favorable reports came constantly from the mine until the new board of directors was elected in August, and then the resignations of Lamb and Brule were requested and the new officers made the examination of the property, finding that the mines had been worked out before they were turned over to the new company. Mr. Gillie finds that the stockholders were not only defrauded in the first instance but that after the organization of the company its affairs were shamefully mismanaged. An immense amount of useless machinery was purchased, "enough to run the Anaconda mines," as Mr. Gillie says. A shaft was sunk at the most inappropriate place, and poor judgment was used in doing development work. A lot of money was spent in erecting a saw-mill many miles from the mine and in sawing a lot of lumber that can never be used by the company. The chief promoters appear to have been the late A. J. Campbell, attorney for the Daly estate, and John C. Lalor, manager of the same estate. Because of the prominence of the name of Daly and the close association of the promoters with leading officials of the Amalgamated Co., the Barnes-King proposition gathered a great and influential following. W. W. Cheely, who represented the promoters in Butte and took the Butte subscriptions, had great faith in the reports of the experts and the judgment of Campbell and Lalor, and is now himself a ruined man because of the investments he made in Barnes-King stock. The promoters claim they paid \$1,200,000 to E. W. King and his associates for the property, but it is known that an option of \$400,000 on the property was turned down by others. The promoters gave the new company the property acquired and a treasury of \$400,000 in exchange for the \$2,000,000. The treasury still contains about \$260,000, which is to be used for development purposes in the hope that another orebody will be found. The mines did not pay expenses for some time before they were turned over to the new company, as the latter discovered when it assumed control and had to pay an overdraft at a bank for \$24,700. Some of the most experienced mining men and the most astute bankers in Butte were taken in on the Barnes-King proposition and lost hundreds of thousands of dollars. It is estimated that nearly \$1,500,000 was taken out of Butte by the apparent swindle. Mr. Gillie says that if \$100,000 had been paid for the property it would have been a high price. Some of the stock-

holders are preparing to institute suit against the persons who are supposed to have benefited by the alleged fraud, and others are threatening to ask for the appointment of a receiver.

There have been few failures among the scores of new mining companies that have been organized to operate in the Butte district during the past two years, but there have been none that can be regarded as absolute frauds or wild cats, though several have been the causes of great loss to investors and have been the subject of severe criticism. The first of these was the Butte Copper Exploration Co., promoted by well known Boston bankers and brokers; the public purchased stock under the belief that the company owned the property it was attempting to develop, but which it only held under bonds and these were allowed to lapse after insufficient work had been done and the treasury exhausted. Another wretched scheme was the Butte Copper Co., the promoters of which did much like the Barnes-King promoters, in that they took in all their friends and sold them all the stock they could. The similarity ended there, however, for after the sale of quantities of stock in Butte the Butte Copper men went to New York and organized a new company on the majority of the stock in the old company, which so discredited the old stock that it has been worthless on the market ever since. This company has also ceased operations, and the stockholders count their money as lost. With few exceptions, all the other companies organized during the height of the copper boom are still working, and a number of them have good chances to develop producing mines.

All work at the Stewart mine in the Cœur d'Alene, owned by F. A. Heinze, has been stopped. The reason for the suspension is not known, but is presumed to be in the fact that the property on which the Stewart mill is situated has become involved in litigation. The mill is on the Silver King lode, adjoining the Stewart, and the Silver King is owned by the Cœur d'Alene Development Co., with which Heinze is in litigation.

Salt Lake, Utah.

Decrease in Copper Production.—General Curtailment.—Lead Output.—The Deepest Shaft.—Shipments From Park City.—Utah-Apex.

The copper mines of Utah have begun curtailing their output. As a result of this, there has been a marked falling off in the demand for labor at the mines and smelters. This slowing down process began at Bingham, where more than a thousand less men are employed than was the case three weeks ago. The first of the big copper companies to decrease the working force was the Boston Consolidated where 300 men were dropped from the payrolls; then the United States Co. shut down its Telegraph mine and practically stopped work at the Galena mine; the Bingham Consolidated fell into line and ceased production at its Commercial mine and a few days ago the Tintic Mining & Development Co. closed the Yampa mine and smelter indefinitely. While the lowering of the price of copper has been an element contributing to this situation, there have been other conditions confronting operators that have made it advisable to ease off at this time. The difficulties experienced in the matter of railroad transport, the shortage of fuel due largely to the inability of the common carriers to meet the demands of consumers, unreasonable demands of labor, and the greatly increased cost of materials, machinery, supplies, and nearly every other thing required in the operation of mining—these factors, in connection with the falling metal market, have caused a serious state of affairs calling for adjustment. It is claimed by operators and engineers that the cost of pro-

ducing copper from the leading mines of Bingham need not exceed 8 or 9 cents per pound under normal conditions; some of them can produce it for much less and this was demonstrated last year by the Utah Consolidated, which has a cost sheet showing the expense to have been a little under 5 cents per pound. The smelting companies operating lead furnaces in the Salt Lake valley have complained of a congestion of ore and have urged the producers to curtail production. Attention is also called to the fact that the time of year has arrived when there is less demand for lead; that like copper, the metal has fallen off in price lately and that a slowing down in production at this time might be the means of averting further depreciation. While no concerted action has been taken as yet, it is believed that many of the lead producers will comply with this request.

No effort has been made toward a settlement of the strike in the Daly West, Daly, and Ontario mines at Park City, and there is little indication that the companies involved contemplate making a change of front. The Little Bell mine, which is practically under the same

Utah.

management, has been shut down because of the agitation for recognition of the union.—The deepest shaft in the State of Utah is in the Tintic mining district and is on the property of the Mammoth Mining Co. It is down 2,300 ft. At this depth the company has encountered some immensely rich bodies of ore, running high in gold. The company is preparing to make a shipment of high-grade ore and it is likely that it will soon pay a dividend. The treasury has something over \$300,000 on hand.—Work in the Uintah Treasure Hill mine at Park City will be resumed in a few days. The shaft of the Creole property, now owned by the Treasure Hill Co., has been cleaned out and put in shape for operation.—The ore production from Park City last week amounted to 1,615 tons, the contributing mines and amounts being: Silver King Coalition, 1,030; Daly Judge, 537; Little Bell, 261; other properties, 22 tons.

The construction of the aerial tramway (12,000 ft. long) of the Tintic Mining & Development Co., at Bingham, is progressing and will be completed in about six weeks. Pending the shut-down of the Yampa mine and smelter, several new furnaces will

be installed at the latter so as to raise the capacity from 600 to 750 tons daily.—The Utah Apex mine is operating with the usual force and is sending ore to the Markham Gulch mill for treatment. The new manager, R. S. Oliver, who was promoted from the position of superintendent, has taken charge, relieving Walter C. Orem, who resigned to give his attention to the operation of the Nevada Douglas Copper Co.'s property at Yerington, Nevada.—The Horn Silver Mining Co. has paid another quarterly dividend of \$20,000. J. M. Ceballos, of New York, is to succeed the late Allan C. Washington as president of the company.

Cripple Creek, Colorado.

New Find in the Abe Lincoln.—A Tunneling Machine.—Promising Discoveries.—The C. O. D. Shaft.—Leases on Bull Hill.—The September Production.

A vein in new territory has been opened in the Abe Lincoln property. This property was recently acquired under lease by Jack Sharp. The vein contains a streak of calaverite varying from a knife blade to an inch in width; assays run into the thousands of dollars.—The plans for the new Trilby mill make it one of the most complete in the district and allow for 100 tons per day. The excavation is finished and the concrete foundation will be started in a few days.—Inventors of rotary tunneling machines are not discouraged by recent failures. Another machine is to be given a trial in the Hull City placer mine on Bull hill within a few days. This machine has 62 piston-drills, the operating principle of which is to chip the hard rock in the same manner as a chisel in the hands of a stone-cutter; the power of a 10-drill compressor is deemed sufficient to run it at full capacity. Fred Russell is the inventor and gave the machine a thorough test in a Denver shop, where it gave promise of success when put to practical use.

In conducting operations deeper than any yet undertaken on the Chicken Hawk property, a new vein has been encountered, which is believed to be an extension of the main Mary McKinney vein, as the ore is a quartz similar to that in the Mary McKinney. Additional interest is given to the find for the reason that it is in virgin territory and assays run from 2 to 4 oz. gold per ton.—Large quantities of low-grade ore are known to exist in the region south of Victor, about Trail Mtn., but no real development work has been undertaken until recently. The Northwestern Co. has installed a modern plant, operated by gasoline and electricity; three Fairbanks-Morse gasoline engines, with a total of 50 hp., operate a 15-kw. generator, which in turn runs the drills and furnishes light for surface and underground purposes. The main shaft is 150 ft. deep and has two compartments 4 by 4 ft. each; it is timbered and ready for installation of cages, which will be put in on the completion of 200 ft. more of sinking. The vein can be traced for a distance of two miles on the surface north and south of the shaft. The plant is also equipped with a complete cyanide mill; there are 4 solution-tanks with a capacity of 45 tons each. Iowa capital is behind the enterprise.

It is announced that the C. O. D. Leasing Co. will rebuild the C. O. D. shaft-house, recently destroyed by fire. A portion of the shaft for 75 or 100 ft. below the collar will need retimbering, and a new plant of machinery will be erected. It is intended to sink from the 900-ft. level to 1,000 ft. and cross-cut through unexplored territory. The C. O. D. mine is one of the old producers of the camp; previous to the fire ore was taken from the upper workings and it is for the purpose of cutting these orebodies at greater depth that the new work is planned.—A mud seam in a vein upon which the

Union Leasing Co. is operating on the Proper claim of the Stratton estate is giving high returns, though it is difficult to separate it from the rest of the ore broken, the width of which is 6 ft. The vein contains fluorite and shipments on an average of two carloads per week are made to the Portland mill at Colorado City.

A number of properties report new strikes. The Western Investment Co., operating on the 400-ft. level of the Morning Glory, is reported to have opened up an ore-shoot from which regular shipments are being made. The vein is 6 ft. between walls and assays from \$30 to \$60 per ton.—The Sitting Bull claim of the Keystone Co. on Bull hill has a new orebody exposed on the 250-ft. level in basalt.—W. J. Hill and associates, in doing development work on the 360-ft. level of the North Burns property, have encountered a new orebody, assays from which yield 5 to 6 oz. per ton; the width of the vein ranges from 7 in. to 3 ft.—The Joe Dandy property has a strike on the 250-ft. level 200 ft. north of the shaft; a vein 3 ft. wide contains a streak of sylvanite giving returns of 27 oz. per ton, and on either side of this streak the ore averages 2 and 3 ounces.

Considering that many of the large properties were short of men in the early part of the month, September exceeded expectations as regards production of ore. The cyanide plant of the Golden Cycle mill, which was not wholly destroyed by the fire, shows an increase in the amount of ore treated, and the Portland mill reports an increase of 1,000 tons; altogether the output was little under that of August. The local mills kept up to their capacity, showing that they are on a solid basis. The Vindicator Co.'s experimental plant has given great satisfaction and a larger mill is reported as assured. Many of the smaller mines closed down or sent their ore to local mills, thus reducing the receipts of the smelters. Following is a table of the tonnage and value of ore treated during September, from which it will be seen that the cyanide mills are steadily forging to the front:

Plants.	Tons.	Average per ton.	Total.
Golden Cycle	24,000	\$ 2.50	\$ 60,000
U. S. R. & R.	12,300	24.00	295,200
Portland	11,500	22.00	253,000
Smelters	4,900	54.00	264,600
Isabella	3,000	6.00	18,000
Ironclad	2,500	3.00	7,500
Phoenix	2,000	2.00	4,000
Vindicator	750	20.00	15,000
Smaller plants	2,000	10.00	20,000
Total	62,950		\$537,300

Pioche, Nevada.

Optimism Dominant.—Confident Outlook.—Nevada-Utah Co.—The New Railroad.—Bristol Con.—Boston & Pioche Co.—The Rights of Surveyors.

It would be hard to find in the West today a mining camp where a more pronounced feeling of optimism exists than in Pioche today. As the region of which Pioche is the commercial and distributing centre is going to produce large quantities of lead and copper, a natural inference would be that the recent depreciation of those metals and the fall in mining stocks would result in gloom here. Such is far from the case. Not a man whom I have interviewed during the past week has shown any evidence of mistrust or apprehension. Perhaps the most interesting fact is that the misfortunes of other camps are regarded here as the most encouraging incidents that have occurred since the contractor began work on the grade last spring.

There are many reasons for this. Calamity has been the portion of these people for a very long time, and deliverance is now close at hand. That is doubtless the

controlling reason. The man who has been living sumptuously and sees himself compelled to retrench and to accept plainer fare may regard the situation unhappily, but the man who has been starved and sees abundant food coming up is not at first likely to grumble if that food is not as choice as some people enjoy. Another reason is that people who look at things from a distance get a better perspective than those who are *in medius res*. In the large financial centres, where stocks are declining and the injured are groaning and exchanging condolences, the atmosphere of distress becomes general and optimism has hard sledding. In a place like this, far from the madding crowd, it is easier to analyze the situation and to realize convincingly that the country generally is prosperous, that seven billions of dollars is going to be soon let loose in return for abundant harvests, and that the need for lead and copper will be greater than it ever was. The law of supply and demand has not been overturned even if Wall Street did have a panic and some rash parties parted from paper profits. Silver and gold are stable and at present will afford the larger proportion of value from the ores of the region, and by the time we get properly started lead and copper should recover some of the price they have temporarily lost. Another reason which appeals to the mine manager here is that he sees better promise of a labor supply. Good miners have been scarce. There has been a disposition to grumble about wages and hints that the high-pressure conditions prevailing at Goldfield will soon be established here. Since the exodus began at Butte things have changed and there seems promise now that Pioche can have all the good miners she needs and that they will be content with fair wages.

Mr. Swanton, superintendent of the Nevada-Utah, told me last week that they are planning more extensive operations even than they contemplated thirty days ago, and actually seemed elated at the prospects rather than depressed because Nevada-Utah stock is just now in the doldrums. And so with Ohio-Kentucky. The Susan Duster is developing a valuable orebody. In the Prince the main shaft is down 250 ft., where the ore is said to be fully as good as anywhere in the mine.

Our branch railroad, which is approaching from Caliente, has been substantially completed to Panaca, the old Mormon town 12 miles below here. A neat freight and passenger station has been erected at that point and an agent installed. Regular passenger service has not been initiated, but the construction trains run on a fairly regular schedule and carry any passengers who desire to ride. The entire grading force is now working within sight of town. Within about two weeks, barring accidents, the grade should be ready for the rails to Pioche station, which will be built about a mile from the centre of the town. Owing to the rapid rise in the ground in that mile the railroad will not approach any nearer for the present. Condor canyon, which begins two miles this side of the Panaca station, was regarded as the difficult part of the enterprise and the one in which the rate of accomplishment could not be closely estimated, but that is now a worry of the past, as the rails are already laid miles this side of it. The steel for the line has been obtained from portions of the main line where the 65-lb. rail to be used on the branch was replaced by heavier steel for the through traffic. This steel has been a little slow in coming in, but the engineer of the branch expects it to come now fast enough so that 2,500 ft. of track can be laid a day until the branch is completed.

The Bristol Consolidated is hauling its high-grade copper ore by wagon to Panaca for shipment instead of waiting for the railroad to reach here. The Mendha and Lyndon mines are also shipping from that point.—A

most important mining transaction was completed last week when the Boston & Pioche Mining Co. bought the famous Yuba East and auxiliary claims and added these properties to their already extensive holdings. The Yuba East is on the great porphyry dike east of the Old Yuba. In the days of the first period of Pioche's prosperity the American Flag on that dike made a great record. In the second period, when W. S. Godbe and his associates were striving to restore this camp to its former activity, the American Flag, rechristened the Yuba, was their great reliance, and is said to have yielded for them over a million dollars. Several years ago, long after this second period passed into eclipse, John R. Cook located the eastern extension of the Yuba, and taking Wm. Lloyd in as partner, started to prospect in their ground for the rich ore which had yielded

Map of Eastern Nevada.

so abundantly in the old mine. It was not long before they struck bonanza ore and began shipping cars of stuff so rich that wealth seemed imminent, when they were stopped by injunction and the mine remained closed until the recent sale removed the embargo. The case was tried, and although there were other points put in issue the only point upon which the court decided against Cook was that because at the time of his location he was a U. S. Deputy Mineral Surveyor, his location was for that reason utterly void. The case was before the Nevada Supreme Court on appeal and a decision had been expected several weeks. Whatever that decision might be it was the determination of both parties to the litigation to carry the case to the Supreme Court of the United States. The Boston & Pioche purchased the claims of each side and while it means a great deal for the prosperity of Pioche to have this important property revitalized it is a serious loss to mining jurisprudence. No adequate motive now remains to induce any one to incur the great expense which would be involved in getting from the court of final resort a ruling on this question, which involves fundamental rights of citizenship. The Boston & Pioche has succeeded to the status of each side to the controversy, and so far as it is concerned the privileges of a U. S. Deputy Mineral Surveyor become purely an academic question. Some years ago this question was decided by the Supreme Court of Utah adversely to the Mineral Surveyor. The case went to the U. S. Supreme Court, which dodged the question and decided the controversy on another point. Other cases involving the same question are now pending in this State, but it seems doubtful whether it will ever be authoritatively settled.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

MALAPAI is a corrupted form of *mal pais*, from the Spanish *mal*, bad, and *pais*, country. It is used in Arizona and the Southwest to designate the black lava-fields or bad lands.

THERE is only one gold dredge in operation in Queensland; this is at Cania, in the Gladstone district. But there are four dredges at work on tin gravel. One of these has paid its first dividend.

THE drip-drop of cyanide over the head of each zinc-box that is precipitating from the weakest solution, makes the zinc more active, so that a precipitation is obtained in a manner usually unattainable from a solution of, say, 0.02% cyanide.

VOLCANIC ash is a misnomer. Ash is the product of combustion; the volcanic 'ash' is the result of violent explosion or fragmentary ejection from the vent of a volcano; it is broken rock that has undergone grinding by abrasion, due to the collision of particles in mid-air. It is dust.

WHEN a valve in a pipe is closed while the water is flowing, the velocity of the water is retarded as the valve descends, and thus a dynamic pressure is produced. If the valve is closed quickly, this dynamic pressure may be much greater than the static pressure, and the result is a 'water-hammer,' or 'water-ram.'

FILTRATION in cyanidation is apt to be hindered by the separation of silica in a colloid form by the action of sulphuric acid (from decomposing pyrite) upon the silicates of alumina and magnesia in weathered ore and old dump. This colloid silica is also likely to explain the film that settles on the zinc in the precipitation boxes, even from a clear solution.

WHEN water is pumped through a pipe from a lower to a higher level, the power of the pump must be sufficient not only to raise the required amount in a given time, but also to overcome the various resistances to flow. The head due to the resistances is thus a direct source of loss, and it is desirable to arrange the pipe so as to render this as small as possible.

ALLOTRIMORPHIC is an adjective used to describe those minerals in an igneous rock which do not possess their own crystal faces or boundaries, but which have their outlines impressed on them by their neighbors. They result when a number of minerals crystallize at once, so as to interfere with each other, and are especially characteristic of granitoid textures.

THE hydraulic ram is an apparatus that employs the dynamic pressure produced by stopping a column of moving water to raise a part of the water to a higher level than that of its source. It has been widely used for pumping small quantities of water, but is not so well adapted to lifting a large quantity. The efficiency of the hydraulic ram is the ratio of the useful work done to the energy expended in the waste water.

WHERE ores of a number of metals are attacked by surface waters, the result of their difference in solubility is the formation of rough mineral belts. These follow the surface in general, and each is characterized by a preponderance of certain minerals. The effect of descending

waters in deposits containing lead, zinc, copper, and iron, is to form galena above and zinc blende below, with often a third and lower zone characterized by copper, and more rarely, a fourth with iron predominating. These zones, of course, are only defined in a broad way, different minerals occurring together.

A owns a placer mining claim; also a ditch which at one time carried water for use on the claim. The mining claim is not now being worked, but **A** disposes of the water flowing through the ditch to others who apply it to beneficial uses. Has **A** the right to dispose of the water, or does his failure to utilize it on his mining claim deprive him of all right to the water, rendering it subject to appropriation by others?

The answer is: One acquiring a right to divert and use water from the running streams for a specific purpose may change the point of diversion, place, and manner of use, if intervening rights are not prejudiced. So long as **A**, or those acquiring rights through him, apply the water to any useful or beneficial purpose, there is no abandonment, and he, or his lessees cannot be deprived of their right by subsequent hostile appropriations. These rights are measured by the extent of actual use and can only be lost by abandonment or non-user for a period of five years. Many of the oldest and largest ditches in the mining regions of California were originally constructed to conduct water for hydraulic mining. Since this industry has ceased, the water is sold by the ditch owners for power, irrigation, and other useful purposes and is delivered at places remote from where the water was originally used. Their right so to dispose of the water cannot be seriously questioned.

An incorporated mining company owns several claims which are not on patented ground; but the title is that of the original locators; the required amount of work being done upon them at stated periods, in the usual way.

The stock of the company is held by two parties, whom it will be convenient to refer to as the Minority and the Majority parties. The Majority, which naturally controls the concern, is careless and indifferent, and among many sins of omission, fails to take proper action to protect the property or provide for the performance of the assessment work; and the Minority, in order to keep the title alive, advances the money required to do the necessary work and takes chances on being reimbursed later.

Several questions arise. One is, what remedy or recourse has the Minority in a case of this kind?

Another is, does the Minority, by so performing the work, the Majority interest having failed or neglected properly to provide for same, although requested to do so, thereby acquire title to the property, *de novo* as an outsider would do? Or would the work so performed be considered as done for and on account of the corporation? The answer is:

Where one of two or more co-owners of a mining claim defrays the expense of performing the annual labor required by law to be performed, he may either compel contribution from the nonparticipating co-owners, or acquire their interest by forfeiture proceedings known as 'advertising out.' Where the property is owned by a corporation, however, the only redress of the contributing minority is by an action against the corporation upon an implied contract to reimburse them for money necessarily expended in protecting the title to the property. Stockholders of a corporation are not co-owners of the corporate property and the forfeiture proceeding of 'advertising out' is not available to the minority furnishing funds to perform the assessment work.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Conveying Tailing in Launderers.

The Editor:

Sir—The courteous query for more light in your issue of September 14, and signed by Mr. G. A. Overstrom, deserves full data in answer.

The conditions are not quite as Mr. Overstrom takes them. The ore crushed is an exceeding hard tough quartz, with very small admixture of calcite, and no other gangue; it is therefore very sharp and granular. The coarser portion of the pulp which results from battery crushing through 26 mesh 28 wire steel screens is tube-milled, and the resulting screen-test after tube-milling is, as follows:

PULP WHEN USING TUBE-MILLS.		
	Mesh.	%
Remainng on	40.....	3.1
"	50.....	4.1
"	60.....	2.8
"	80.....	4.1
"	100.....	4.3
"	120.....	10.0
"	150.....	3.1
Passed	150.....	68.2

The line has for several weeks at a time, however, been run without the tube-mills running, therefore taking the straight battery product, screen test of which is as follows:

STRAIGHT BATTERY PULP.		
	Mesh.	%
Remainng on	40.....	5.1
"	50.....	5.2
"	60.....	5.2
"	80.....	5.7
"	100.....	5.6
"	120.....	11.8
"	150.....	1.7
Passing	150.....	59.7

The normal proportion of water that these pulps contain in the pipe-line is about five to one by weight, and while there is no doubt that the hydrostatic head formed behind riffles of sand in the pipe *when such occur* greatly assists in preventing the complete clogging of the pipe, this action has only occurred a few times in the eighteen months that the pipe has been running, and normally has no influence whatsoever. Under normal conditions, embracing all but a few hours since the line was installed, there are no riffles whatsoever in the line and the upper three-quarters of the pipe is entirely clear, the pulp flowing in a smooth rapid stream without ripples or disturbance in the lower quarter of the pipe, precisely as in an open launder. I may say that since adding the second 80 stamps, the line which now carries pulp from 160 stamps is running slightly less than half full.

Mr. Overstrom's difficulty in reconciling the performance with many detailed experiments is shared by many. During the time of installation of the line the number of expert opinions passed upon whether it would run or not and based upon experiences with launders, was very large and with one solitary exception, flatly unfavorable. We had, however, demonstrated experimentally that pulp much thicker than that now being handled and somewhat coarser, would run freely in an identical pipe-line 300 ft. long on a 2½ % grade—running so freely, in fact, that we felt justified in going to a 2¼ % grade to better fit the contour of the country.

The limitations of the line seem clearly marked. With the tube-mills running, no tendency to clog has ever been discovered. With the tube-mills out and on straight battery pulp if the water is reduced to less than five to

one, riffles of sand commence to form at a point about 500 ft. from the upper end of the line, giving notice there by a whistling noise, due to the air disturbance in the pipe, which issues through a blow-hole placed at that point. The restoration of the proper dilution at the thickening cones at once corrects the fault.

The economic importance of being able to transfer tailing over great distance at such small grades and at practically no cost (as evidenced in our expense of P3.57 as the total charges against the carrying of 100,000 tons of ore a mile in distance) is considerable, hence the intrusion upon your space with the foregoing detail.

The wear upon the line to date is not measurable after eighteen months' service.

C. W. VAN LAW.

Guanajuato, September 28.

[In behalf of our readers we thank Mr. Van Law most cordially for these valuable data.—Editor.]

Methods of Advertising.

The Editor:

Sir—Your recent discussion regarding the selling of advertising space by the American Institute of Mining Engineers, has suggested some thoughts which I think it well to offer, whatever may be their destiny in action. Necessity is the Mother of—several things; and Dr. Raymond's suggestion that advertisements be used as a natural and suitable support for the finances of the Institute is well made, and should be carefully and favorably considered; and herein, it seems to me, there lies a great opportunity. This suggestion is not new; it is as common as the annual banquet of the advertising associations; but the idea that it is possible to make the advertising pages of any reputable publication as valuable and as interesting to the reader as the body of the text, is certainly worth following out. No one can give any attention to the remarkable phenomenon of advertising in the modern press without being struck by the fact that not half of the advertisements are well written, and not half of these are properly displayed. Now here is something which needs the attention of the editor of the publication in question, and also by the man who pays for the advertisement. And usually these are the two people who neglect both the phrasing and the display of the advertisement. The latter, the display of the advertisement, is usually left to the foreman of the composing room, or to an over-worked 'advertising editor;' whereas both the display and the wording of the advertisement should be the subject of careful study on the part of everyone concerned. It is possible to tell something in connection with every advertisement which shall be directly connected with the subject matter of the advertisement, which shall be interesting, and which shall be valuable. This idea is possible of almost infinite development and its proper execution will mark a new departure in the history of advertising. A few cases are known where information has been given in connection with advertisements; thus the short series of illustrations showing the different stages in the making of a collar button, another series showing the successive stages in priming, filling, varnishing, and polishing the surface of a well-known make of wagon, are in point. Of course, one will not look for a complete encyclopedic treatise on every subject which is advertised; but the idea of giving some helpful information in connection with every advertisement will draw attention to the advertisement; it will help the advertiser, and it will help the publisher. Every advertisement ought to have a short clear paragraph written in newspaper English, or the English of the street, direct and concise without

being vulgar or careless, which may tell something new but always something interesting and useful. The salesman for the object covered by the advertisement in question always has these paragraphs on his tongue's end—why not put some of them into the advertisement? Why not let the manufacturer put a line or two of his own experience and judgment into the advertisement to help other men? But further enlargement is not necessary. The idea is here; and however difficult to execute, it has come to stay; neither the American Institute of Mining Engineers in its proceedings, nor any other reputable publication, has anything to lose by the wise and judicious use of advertisements. Indeed, as Dr. Raymond says, they contribute directly to the history of the progress and status of the art and however difficult to execute, the idea will undoubtedly be worked out, and successfully. However crude this presentation, I hope that the suggestion may be given the prominence it deserves.

CHARLES S. PALMER.

Boston, October 2.

The Blow Out.

The Editor:

Sir—Referring to the article by Mr. Garrison in your issue of September 28, the very expressive term 'blow out' is, I think, of Australian origin. I found it in common use among miners and mining men in that country in 1884. There it is always used as a term for an isolated mass or small boss of rock, never for a "relatively small narrow mass of rock forming a ridge, rib, or dike, sometimes continuous over a long distance." Such a deposit would be a 'reef,' synonymous with our vein or dike. The word 'blow' also usually carries with it an idea of poorness or barrenness, though often qualified as "a barren quartz blow."

The now famous Mt. Lyell mine was for many years known as the Iron Blow, the blow consisting of a mass of hematite projecting from the ground, somewhat resembling Fig. 1 of Mr. Garrison's article as to situation and size, and having a length of 100 ft. by about 40 ft. in thickness before uncovering. Blows are often used as landmarks or points of locality, as Morris' Blow in the Silverton district, New South Wales. The words 'blow out' would only be used in a descriptive sense as "a great blow out of white quartz, etc." Fig. 3 and 4 would hardly be referred to as blows. They do not stick up out of the ground enough. Fig. 3 would be referred to as a 'half buried reef;' Fig. 4 as a 'low bluff' or a 'low bench of rock;' Fig. 1 and 2 are typical blows. The word 'blow' as applied to isolated outcrops of rock without length is descriptive and satisfactory, if not scientific.

G. F. BEARDSLEY.

Fruitvale, Cal., October 3.

BARYTES or heavy spar is barium sulphate, the chemical formula of which is BaSO_4 . The mineral is composed of barium monoxide (baryta, BaO), 65.7%; sulphur trioxide (SO_3), 34.3%. The specific gravity is 4.3 to 4.6; the hardness, 2.5 to 3.5. Barytes is usually a white, opaque to translucent crystalline material, about as hard as calcite, but differing from the latter by its greater weight and the fact that it does not effervesce with acids. A common form of the mineral is that of an aggregate of straight or slightly curved plates. It also occurs in granular, fibrous, and earthy masses, and in stalactitic forms, as well as in single and clustered crystals. In nature the material is rarely pure, the most common impurities being silica, lime, magnesia, and the oxides of iron and aluminum. Commercial grades as mined carry 95 to 98% barium sulphate and 1 to 3% silica.

Right of Mining Locators to Cut Timber in Public Domain for Mining Purposes.

The following query has been sent to us:

"May a person cut mining timbers on 'vacant' land—that is, on either agricultural or mining land which lies handy to his claim, but which is still 'government' land? Or must he confine himself to his own mining claim?"

On this subject the views of Mr. Samuel Platt, United States District Attorney of Nevada, who, under instructions of the Government, is engaged in investigating timber depredations at Manhattan, Nevada, are quite opportune. We quote from an interview appearing in a local paper:

"The law relative to the use of timber upon a mining claim has been very often misconstrued, and in many instances its provisions grossly abused. Until a title in fee by United States mineral patent has been secured by the locator of a mining claim, or his grantee or grantees in interest, the Government retains right to the timber upon his claim. While a possessory owner of a mining claim, performing every act required by the law to hold and work his claim, is for all practical purposes an owner in fee, yet until he receives his patent, the title to the land is in the Government and the right to the use of timber thereon is subject to governmental regulation and control. If it were not for this construction of the law, every mining community could be deprived of all right to the use of timber for building and domestic purposes by a few unscrupulous timber speculators, locating so-called mining claims with no intention of ever working them as such. On the other hand the mere possessory owner is simply encouraged to use whatever timber upon his claim may be necessary for legitimate development of his property. Good faith is the essential thing, and when this is shown, the courts have even given the locator the right to use timber growing on Government land which may be adjacent to his claim and which has been shown to be mineral in character and manifestly unfit for agricultural or other purposes."

To this we may add the following as a matter of general interest to owners of mining claims:

The right to cut timber on unreserved nominal public lands for mining purposes is also given by statute, but this right must be exercised in good faith and in accordance with the rules and regulations which the Secretary of the Interior may from time to time promulgate. Timber so cut must not, however, be transported for use beyond the borders of the State where it is cut. The aim and policy of the law is to enable actual settlers and bona fide locators of mining claims to obtain the timber necessary in the development of their claims and at the same time so to limit and regulate the right as to prevent the wanton destruction of the timber, or its use for commercial purposes.

Where public lands have been included within the limits of a forest reserve, the right to cut timber for mining purposes is so guarded by the Department that it is available under existing regulations only to bona fide miners or prospectors who are personally and in good faith developing their own claims without the assistance of hired labor and who need the timber for the purpose of placing the mine upon a paying basis. Companies and corporations are denied the right, and they, along with the owners of revenue-producing properties, must purchase their timber. No timber may be cut without a permit therefor. Timber from one mining claim may be used on another claim only when they are contiguous and part of a single group of claims which have been located in good faith and not for the purpose merely of obtaining the timber for use on denuded claims.

Handling Residue.

The accompanying photographs, which we owe to Mr. D. E. Bigelow, illustrate the manner of handling the tailing from the South Blocks plant at Broken Hill, New South Wales, and at the Oroya-Brownhill mill, at Kalgoorlie, Western Australia.

The South Blocks mill is peculiar as compared with

launder delivering to the product-bins at the railway siding. There are two of these bins, one being filled and drained while the other is being discharged into the railway trucks. The residue coming away from the Wilfley tables is raised on bucket-elevators and laundered into a nest of settlers, as shown in the photograph. The settlers overflow clear water into the storage-vat, in the foreground, while the down-flow from the

The Tailing-Stacker at the South Blocks Plant, Broken Hill.

Tailing-Conveyor at the Oroya-Brownhill Mine.

other mills at Broken Hill in that there are no trucks used on the surface. Bewick, Moreing & Co. installed the first skips that have been used at Broken Hill for hoisting from the shaft, and these dump direct into a rockbreaker, which in turn delivers onto a belt-conveyor, which empties into the mill-bins. The concentrate from the jigs and Wilfleys discharges into launders, which deliver to an elevator boot, to be raised thence to a high

pointed boxes is run onto a broad draining-belt; this belt is 3 ft. wide and 30 ft. long between centres of terminal pulleys. By means of troughing idlers a basin is formed on the top into which the wet pulp is discharged. The pulp is thickened as much as possible by means of the pointed boxes and a small amount of slime overflows from the tail pulley. The belt runs at a slow speed; the upper pulley, being some-

what higher than the basin, throws the sand with a portion of the entrapped slime onto a standard belt-conveyor, which delivers to the dump. After this dump is built up and settles firmly enough for a foundation, a boom-stacker is to be erected which will carry a belt 60 ft. long at 30° incline and be capable of swinging through a horizontal arc of 180 degrees.

Acetylene Lighting.

By N. GOODYEAR.

*A pound of absolutely pure carbide will yield from 5.5 to 5.8 cu. ft. of acetylene, but chemical purity is not practically possible from an economic standpoint. Between 4.25 and 4.75 cu. ft. is the average efficient yield when used in a good generator. The relative quantities, by weight, of water and carbide necessary to form acetylene and dry slaked lime are 36 parts of water and 64 parts of carbide, which yield 26 parts of acetylene and 74 parts of slaked lime. Water will, therefore, decompose nearly twice its weight of carbide, theoretically, but in practice, in a good generator, about 17 times this quantity is used. The reason for this is that the decomposition of carbide and water into acetylene and lime liberates heat. The quantity liberated from good carbide is 406 lesser calories per gram of carbide, or 730.73 B.T.U. per pound of carbide. One pound of carbide will raise the temperature of 8½ lb. (one gallon) of water about 87° F. Cool generation is essential, as at temperatures in the neighborhood of 700° C acetylene becomes polymerized, forming benzene and other hydrocarbons which condense in the pipes and cause great difficulty.

For the above reasons a good generator should be constructed on the principle of dropping a small quantity of carbide into a relatively large quantity of water. A few years ago, before these principles were understood, nearly all generators were made on the reverse principle, dropping a small quantity of water on a relatively large body of carbide.

Acetylene is conveyed from the generator to the burner through ordinary gas-pipes, but on account of the relatively small quantity of acetylene necessary to give an illumination equivalent to ordinary illuminating gas, much smaller pipes can be used; that is, pipes of half the diameter are ample for the same number of burners. For practical purposes it has about two and one-fourth times the heating capacity of ordinary gas; its calorific value being 1,504 B.T.U. per cubic foot.

In this connection, however, it should be made clear that acetylene for lighting purposes is much cooler than ordinary gas on account of the small quantity consumed to give a stated amount of light, being nearer the electric light in this respect than any other gas. Compared to ordinary 20 candle-power gas it actually emits one-fourth the heat while giving the same light.

According to Prof. Vivian B. Lewes, acetylene is what might be called a 240 candle-power gas; that is, an efficient 1-ft. burner will give 58 candle-power; but, as with electric lamps, efficiency is dependent upon various factors, such as the size and make of the burner.

Some of the most misunderstood facts concerning acetylene are those relating to its safety. It has been shown that acetylene is far less poisonous than the usual illuminating gas sold in cities. It is still to be said that far less gas can pass through an acetylene burner, ½ ft., than would pass through an ordinary coal-gas burner, 5 ft., assuming that both are accidentally left fully turned on and gas escaping at full head. Asphyxiation, in the sense in which we know it as resulting from respiration

of coal gas and stove gas, is entirely unknown to the character of acetylene.

The combustion of all oils or gases used for illumination pollutes the air in an unventilated space. Since the results of burning acetylene are exactly the same in character as when petroleum or coal gas or water gas is used, namely, robbing the air of oxygen and charging it more or less with carbon dioxide; since acetylene, on account of its great brilliance, is used in remarkably small quantities as compared with other gases, one-tenth the volume giving the same amount of light; it would be manifestly unfair to acetylene to dwell on so remote a possibility of danger. It offends only one-fourth as much in this respect as does ordinary illuminating gas.

In case of acetylene or any other combustible gas whatever, two things are necessary for explosion: 1. Admixture with air. 2. Ignition. The gas must escape and ignite. In no other way can explosion result. Suppose a jet of gas is left open; it passes at most a foot of gas in an hour. A room 10 ft. square and 8 ft. high, scarcely more than a closet, is certainly small enough to make a fair illustration. Granted that this room is perfectly gas-tight—a highly improbable condition—in just 24 hours enough gas will be admitted to charge the air of the room to the lowest explosive limit, of 3%. Still this mixture must find a way to become kindled before explosion can possibly ensue. Acetylene in the gaseous form at ordinary temperatures is not explosive in any sense except as referred to above, when mixtures with air become ignited. Acetylene in the gas-pipes or generator cannot be exploded by electric sparks, heat, or concussion.

Work in connection with the opening of the new coal mines situated in the Campine district, in Belgium, is reported as going ahead in a satisfactory manner. In the commune of Zolder the sinking of the first pit is nearing completion, and the company working this concession proposes sinking a number of other pits. At Coursel four pits will be sunk. The two most important companies holding concessions in the district of Mechelensur-Meuse have amalgamated, and the preliminary work of opening these mines is going ahead rapidly. At Asch the work of exploiting is also being pushed. The most engrossing question in connection with the opening of these new mines, and one that holds out little hope of satisfactory settlement, is the difficulty of securing sufficient labor to operate the concessions. It is estimated that about 10,000 Flemish workmen are at present employed in the Wallon districts, and it is thought that nearly all of these men will return in time to take up work in the mines; but this number is not nearly sufficient to meet the demand that will be created. Each of these concessions to be successfully operated will require probably from 2,000 to 3,000 men, and no one seems to know where they are to come from. Already the agricultural interests are complaining of the scarcity of labor needed to handle the crops, so that unless the present supply of labor can be largely augmented, the companies proposing to operate the new concessions will find themselves seriously handicapped.

AGATE is obtained in considerable quantities in India and is exported both to Europe and to China, as well as worked at some points by native lapidaries. Its source is in the amygdaloidal portions of the Deccan trap flows, and it is collected at numerous places along or near the edge of the trap, especially in the State of Rajpipla, from a conglomerate near a village named Ratanpur. The principal place where it is sold and cut is Cambay, in the Bombay Presidency, though agate cutting is also done at Jabalpur and some other points.

*Abstract of paper read before the Illuminating Engineering Society.

The Diamond Core-Drill in Prospecting.

(Written for California Miners' Association but original burnt in the fire of April, 1906. Now first published.)

By LEWIS T. WRIGHT.

Having had considerable experience in the use of the diamond-drill, I am frequently asked for particulars as to what it can do, or will cost, or for advice as to its applicability. It is exceedingly difficult to answer such questions, even approximately, without a full knowledge of the particular circumstances. I have prepared these notes in order to give engineers who may not have used the diamond-drill some basis for estimating or weighing its advantages or disadvantages for any cases of prospecting they may have in mind. I do not intend to give any instructions as to manipulation of the machine; this must be known to the skilled operator and only a skilled operator should ever be employed for such work.

Diamond-drilling has two prominent advantages. The high speed of operation and the low cost, as compared with driving or sinking by hand or machine-mining, render it a most effective agent. The disadvantage of the small extent of a true orebody that can be sampled by one drill-hole can be compensated for generally by a 'fan' of two or more drill-holes.

The rate at which holes can be drilled depends to some extent upon the hardness of the rock, but by no means upon this alone. The best ground for drilling both as regards speed and loss of carbon (diamond) is often hard, firm ground. Ground that contains soft places, which cave in and clog the drill rods, is most dangerous, not only resisting their rotation but also preventing their extraction, and in such ground a bit with valuable stones may easily be lost. Such ground is not suitable for diamond-drilling without casing. Fissures, or fractured ground from which small pieces of hard rock or quartz may fall into the hole, may interfere with the rotation of the rods and cause the loss of diamonds, on the drawing out of the bit. The best ground for drilling is a moderately hard but even formation, free from broken rotten places, or seams or fault-planes with drag. The casing often indispensable in passing through soft ground or the reaming out of a hole to recover lost rods result in much loss of time. No doubt in hard firm ground the drilling proceeds slowly, but in such cases progress is sure and the rock cores well. In very deep holes the time spent in raising rods for the examination of the bit and lowering is severely felt; but a deep hole generally means good drilling ground. Of course, all other things being equal, the deep hole would go slower on an average than the shallow, but there are many difficulties that cause delay other than the hardness of the ground to be penetrated. In a general way, the influence of depth of hole as affecting the average rate of drilling is felt, but it often happens that the speed of the drilling of one hole to 1,000-ft. depth may average as well as that of another to only 200 ft. in more troublesome ground. In hard ground, such as silicified felsite, I have found in exceptional cases drilling to go as slow as an average of five to seven feet per 10-hr. shift, with holes of moderate depth, say 300 to 500 ft., but in a general way in what is considered by drillers to be hard ground the drilling will proceed for holes to 200-ft. depth at the rate of 20 to 25 ft. per shift; from 200 to 500-ft. depth, at the average rate of 15 ft. per shift; and from 500 to 1,000-ft. depth, at average rate of 12 ft. per shift. It may happen that particular holes average 20 ft. to 500 ft. per shift, and one of the same depth, owing to special difficulties and interferences due to the broken or soft character of the ground passed through, may only average 10 ft. per shift.

As regards ground that is difficult on account of ex-

treme hardness, an average of 5 to 7 ft. per shift is the slowest in my experience. There is a case cited by the Ontario Bureau of Mines, of exceptionally hard granite and some quartz, that drilled at the average rate of 4 ft. 3 in. per shift. The same report mentions limestone that was drilled at the rate of 30 ft. per shift (presumably one shift). Carson gives* the following daily rates of progress:

Rock.	Ft.
Hard gneiss.....	11 to 12
Decomposed gneiss.....	23 to 28
Clay, gravel, and boulders.....	7 to 9
Clay and gravel.....	25

Riley, in hard sandstone and conglomerate, shows an average of 19 ft. per shift. From 33 ft. 7 in. for a hole of 640 ft. to 7 ft. 2 in. for a hole of 373 ft. depth.†

The influence of great depth is shown in the case of a drill-hole in the Transvaal that went to a depth of 5,560 ft., which averaged 13 ft. per day of three shifts, or 4½ ft. per shift, of eight hours. It required seven hours to raise and lower the rods to a depth of 5,000 ft. In the Rand, the ground is considered to be exceptionally good for drilling and short holes drill at the rate of 80 ft. per day.

From the foregoing, a general idea of the speed of diamond-drilling can be formed and compared with driving with compressed air rock-drills, it is seen to be vastly superior. Of course, in the one case a small borehole is left, of no value; in the other, there is a mine working useful for extraction or for development. In ground that, with three shifts working at high pressure, would average 10 ft. per day, for drifts of 1,000 ft. long, it might be easy to put in a drill-hole at the average rate of 40 ft. per day, or four times as fast. Hard ground in which progress could be made by driving at the rate of 5 ft. per day could be easily drilled at the rate of 20 to 30 ft. per day by the diamond-drill. Thus in many cases, special information that a diamond-drill core can afford, could be obtained in one-fourth the time required to obtain it by driving with the best mining methods. The rate of drilling is one of the principal elements of its cost, and that is why I have enlarged upon it.

The loss of carbon by wear and tear in drilling depends chiefly upon the hardness of the ground. It is true that some carbons are softer than others, but for a large amount of drilling, this will maintain an average, for it is hardly likely that all the carbons will be soft. There is about 10% of the weight of carbon purchased that may not be actually exhausted by abrasion, but is lost in splinters or in stones reduced by wear, so as to be no longer serviceable in drilling and having a selling value that is nominal. The black diamond, or carbon, used in drilling, which formerly cost \$10 per carat (1 K = 1 carat = 205 milligrams) now costs \$85 to \$90 per carat. Many of the published costs of diamond-drilling are for work done when carbons cost from \$10 to \$12.

What is the consumption of carbon, both that actually used in abrasion as well as that rendered unserviceable in drilling? This is most important: It depends as before remarked chiefly on the hardness of the ground. The greatest consumption I have noted is 0.08 K per foot drilled. In the case of the hole drilled by the Ontario Bureau of Mines in intensely hard granite, the consumption of carbon was also 0.08 K. In my experience in Shasta county, California, in hard felsite, said by experienced drillers to be harder drilling than in the iron ranges of Michigan, the loss of carbon may amount to 0.04 K, in exceptional cases, and even in rare cases, to 0.08 K, but on an average, for such hard silicified acid eruptives, from 0.01 to 0.025 K might be expected. In the Rand, where the ground is hard, but even and good for drilling, a consumption of 0.02 K per ft. drilled has

*Trans. A. I. M. E. 1890.

† " " 1876.

been noted. In the iron ranges of Michigan in jasper, iron slate, hematite, dioritic schist, from 0.012 to 0.027 K has been recorded.

In addition to the loss by abrasion and reduction of carbon to unserviceable size, an accident may happen by which carbons are lost. The whole bit may be lost. A stone may be pulled out in the lifting of the rods. This is attributed sometimes to a small pebble that has fallen as a broken piece of rock, from the side of the hole when in broken ground, which piece of rock jams between the rod and the side of the hole and rolls around with the rods. The drill-runner if careless may start drilling without water and tear and burn the bit. The rods may clog in the hole from soft sticky ground, which should have been cased, and be torn apart on lifting, leaving the bit, irrecoverable, in the hole. With skilled men these accidents do not often happen, but they have occurred. No doubt most of these accidents could be avoided by extreme care and caution. It happened to me once that the bit unscrewed. Why that happened was never quite clear, but it was connected with a large vug or cave that was encountered in the drilling. It is unsafe to drill in soft ground, and in hard ground, seamy and fractured, great care must be exercised to avoid the stones being torn out of the bit. It is useless to begin diamond drilling without a thoroughly competent and careful bit-setter and drill-runner. Having indicated sufficiently what are the speed of drilling and loss of carbon in different classes of ground, it will be possible to discuss the question of cost.

In regard to labor for operating the drill; the crew will be assumed to consist of a bit-setter, two runners, and two helpers for two shifts, at a cost of, say, \$17 per day of two shifts, though one bit-setter should be able to set the bits for two drills. Thus, for a hole averaging 20 ft. drilled per day of two shifts (not very fast), we have a cost of 85c. per foot for drilling crew. For extremely hard ground, the cost would hardly be twice that, and for softer, but firm rock, one-half. There are, however, other labor expenses, such as cutting cordwood, as well as in grading drill-stations, making trails, handling and packing supplies. The extent of this must depend upon the locality and nature of the work. The cost of cordwood alone amounts to 25c. per foot drilled, where wood-choppers are paid \$2.50 per day. Sundry supplies, lubricants, and so forth, may cost 15c. per foot drilled.

The cost of drilling will therefore depend upon the circumstances of the case. Let us suppose a case of hard but firm ground that offers no other difficulty to its penetration by the diamond-drill than its hardness. In such ground the wear of carbon may be 0.025 K at \$90 per K, and the rate of progress to 1,000 ft., 20 ft. per day. The cost might then be:

Item.	Per foot.
For labor operating the drill.....	\$0.85
Carbon 0.025 @ \$90.....	2.25
Cordwood (or other power).....	0.25
Sundry supplies.....	0.15
	<hr/> \$3.50

In less hard ground that drills at the rate of 50 ft. per day of two shifts and with a consumption of carbon of 0.01 K per ft. the cost might be estimated as follows:

Item.	Per foot.
Labor for operating drill.....	\$0.34
Carbon 0.01 K @ \$90.....	0.90
Cordwood or power.....	0.25
Sundry supplies.....	0.15
	<hr/> \$1.64

These two estimates will fairly represent the two extremes.

This does not include any superintendence other than that of the bit-setter, who is generally the foreman, or

expenses in getting the machinery onto the ground, or wear and tear of machine, drill rods, boiler, or tools, or loss in value of equipment. These other items will be very much affected by the amount of drilling done in the campaign. The diamond-drill requires steam, compressed air, or electric motive power. It would be well if some gasoline motor could be devised, to save the heavy expense of moving a boiler in difficult country, or the consumption of water where this is scarce. Also the discovery of a substance (such as might be made in an electric furnace), that would be a substitute for the now enormously expensive carbon or black diamond. As regards cost, it will be readily seen that an orebody could be reached and a core sample taken at a cost less than one-third the cost of driving, and in one-fourth the time. It is only with the full knowledge of the circumstances governing each that an engineer is able to decide whether to diamond-drill or to drift or sink.

A drilling machine with its equipment, to drill under ordinary circumstances to a depth of 800 ft., will cost f. o. b. Chicago about \$3,000. This does not include diamonds. The engineer can estimate the amount to be charged to the drilling for the amortization of the capital outlay for the drill and its equipment. It would seem that where the amount of drilling to be done is but a few thousand feet that it would be better to contract for it rather than to buy an outfit and organize a drilling crew.

THE Canadian Government recently published the report of a commission appointed to investigate the zinc resources of British Columbia. The conclusions drawn are that although the zinc industry is yet in its infancy in British Columbia, it is capable of great development. While several of the mines now being worked are essentially zinc mines, there are some silver-lead mines in which zinc blende is found in considerable quantities. Until recently the zinc in the silver-lead ores was regarded as an impurity to be gotten rid of by the easiest and cheapest means possible. The increased demand for zinc of late has made valuable as a by-product this zinc blende, which was formerly a troublesome impurity. The commission regards 15,000 tons of zinc ore of 50% grade as a liberal estimate of the present annual production of the Slocan district, and it is calculated that the Ainsworth district can produce 100 tons daily of 50% ore. There are many mines and prospects in other portions of the Province which are supposed to carry zinc in paying quantities. A zinc smelter has been established at Frank, Alberta, the plant being close to a coal mine and on the route from the mines to the market. The large amount of fuel required in reducing zinc ore renders it necessary that coal shall be near the smelter.

MINING IN TURKEY.—In the past six months more than 160 petitions have been presented to the authorities for prospecting licenses in the Vilayet of Trebizond, Turkey, most of the mines in question being situated between Kerassund and the Russian frontier. The whole of this country, to a distance of 10 hours from the shores of the Black Sea, would appear to be extremely rich in minerals. Doubtless much wealth is still awaiting exploitation, and the late rise in the price of copper seems to be tempting capital from certain quarters to enterprises which, owing to obstacles that should not be insurmountable, have missed prosperity of recent years. In the Vilayet of Trebizond are to be found manganese, copper, silver, lead, and zinc, and iron is everywhere abundant and within such easy reach that villagers extract, smelt, and fashion it themselves into implements of everyday necessity. Mineral springs are plentiful, and many of them appear to be of medicinal value.

The Nile as a Mining River.

Written for the MINING AND SCIENTIFIC PRESS
By ALEXANDER DEL MAR.

It may appear surprising that the Nile, which from time immemorial, has been regarded chiefly as a great agricultural stream, should be classed among mining rivers; yet there is ample warrant for so doing. Not only this, but its history as a mining river appears to be more ancient and—considering the geographical changes it has brought about—it is certainly more important than when viewed from an agricultural aspect.

In the remotest historical period, the Nile, though never a rapid stream below the junction of the Blue river, had undoubtedly a greater fall than at present. The occurrence of rock at numerous places in the bed did not as now form merely rapids, but cataracts, as their ancient names attest. The hills of Sennaar and Nubia, which are now destitute of timber and water, were once wooded, and from their flanks flowed numerous feeders, which, after enriching the soil, added their floods to the Nile. These feeders now flow underground, through the mining debris which underlies the plains. Klunzinger's 'March from the desert of the Nile to the Red Sea,' contains many allusions to these streams, for example: "Channels are seen on the sides of mountains, traces of brooks, of waterfalls, of the beds of rivers, some of them strewn with wide valleys of embouchure. Nay, along the very summit of the mountain mass runs a regular water-shed, from which waters must run either westwards into the Nile valley, or eastwards into the Red Sea." "The soil in which we are marching is not loose sand, but very solid gravel."

The Bisharee or gold country was once cultivated and populous. "That the valley was once a busy scene of life is evidenced by the numerous ruins and ancient Egyptian sculptures hewn on the rocks," says Klunzinger. It is now and has been since the time of Cambyse, a vast desert of sand and gravel. The Nile, which now washes the Arabian side of the valley, formerly skirted the Lybian side. There are still some traces of an ancient river-bed along the western hills. From Lat. 27° N. to the sea, a portion of Egypt was at one time a morass. It seems to have been like the Po and the marshes of Lombardy during the Middle Ages. This was probably during the first era of mining and before the river was diked by Menes; it is now all dry land and treeless. The Nile once emptied into the sea, a little below where Cairo now stands. At the present time it runs 90 miles farther, through a delta whose vast dimensions owe their foundation to the operations of those multitudes who for countless generations were employed in washing the sands of the Bisharee region for gold. The certainty that at least a portion of the vast quantities of gravel and sand which can be seen to have been washed down from the Bisharee region, lies beneath the loam which now covers the Delta, defeats all devices for maintaining the level of the water in the canals and reservoirs by pumping, bailing, and lading. This work and the digging of fresh canals engross the labor of the people for months. Without this incessant struggle with nature the land would become uncultivable and even with it, the result is often doubtful; for if the next overflow of the river exceeds 30 ft. in height everything on the land is demolished and swept away; while if it fall short of 18 ft. the harvests fail and famine ensues. The abject and defenseless character of the people that had to depend upon it for support, explains the frequency of their subjection to foreign conquerors and the great number of alien dynasties to which Egypt has been compelled to submit. Dur-

ing the course of 26 centuries these have been no fewer than 16 in number, with an average duration to each dynasty of not more than 165 years, as follows: B. C. 525, Persians under Cambyse; B. C. 411, independent Egyptian kings; B. C. 351, Persians; B. C. 332, Greeks, under Alexander; B. C. 30, Romans, under Augustus; A. D. 616, Persians; 626, Romans; 639, Arabs; 1171, Turks; 1250, Mamelukes; 1517, Turks; 1798, French, under Napoleon I; 1801, British protectorate; 1802, Turkish protectorate; 1804, independent Pashas, like Mahomet Ali; 1881, British protectorate. This furnishes a curious contrast with China, which during 40 centuries has not changed its dynasties half a dozen times.

The civilization of Egypt, like that of most ancient countries, appears to have begun in the hilly regions. Before the Delta assumed its present vast proportions the only considerable agricultural surfaces in Egypt were in the Fork (anciently called the Island of Meroe), in the plains below the Fork, and in the foothills of Nubia. The edifices and works of art discovered in Meroe and elsewhere in Nubia and Upper Egypt appear to have preceded those which have been found in the lower country. The Egyptians and Nubians are regarded as of Indian origin. Their physical appearance, their complexion (that they were not black like the Ethiopians is noticed by Pliny and Rawlinson), their pyramids and earliest edifices, their ecclesiastical and political institutions, and the origin of some of the plants and many of the articles of commerce found in their tombs, all point to this conclusion.

The term Nubia appears to have originated in Egypt, where Nob or Nub signified gold, hence Nubia, the land of gold. Nubia has been regarded as the Ethiopia of the ancients; it embraces the foothills of the mountainous ranges that constitute a great part of Abyssinia. Egypt is a country where the characteristics of all great gold mining countries are apparent, thus, the Sierras, Abyssinia; the foothills, Nubia; the plains, Egypt; the connecting link between them all, the Nile. Analogous geographical surroundings characterize the Po, the Rhone, the Rhine, and the Sacramento. Like Italy and Abyssinia, Nubia has also its coast range. This separates the Bisharee country from the Red Sea and rises to an altitude of 6,000 ft. Below the foothills of Nubia is a vast expanse of sand and gravel, known as the Bisharee or great Nubian desert. This, as we shall presently see, was once the centre of the greatest gold mining works known to the ancient world. According to Diodorus, the Pharaohs derived from this region in gold and silver, a sum which Jacob computes to have been equal to \$30,000,000 per annum. If this computation can be depended upon, the Nubian mines were as prolific as have since been those of either Italy, Spain, Brazil, Russia, Australia, or California.

In lower Nubia, in or about the same latitude as the second cataract of the Nile, lie "vast and fertile, but neglected, plains, which, it is conjectured, were, at some remote period reached by the inundations of the Nile," says the encyclopedist. If the inundations of the main stream could have reached these plains at any former period, they certainly can reach them now, when the bed of the river is higher than it ever was before. At Thebes it has been raised seven feet in 1,700 years and at the Delta more than half as much. So that the encyclopedist must be mistaken as to the cause of the desolation noticed. The fact is that anciently Nubia was watered by numerous small streams that flowed into the Nile and were employed to irrigate these deserted plains—once the Lombardy of Africa—but which, after they had been diverted by the gold miners, and their sources of supply destroyed by the felling of mining timbers in the foot-

hills, fell into the condition of 'washes,' which now are only flooded for a brief period during the rainy season, March to May, and are dry for the remainder of the year. These dried-up water-courses are called by the Arabs, 'wadies.'

Such is Nubia today. Its hills have been leveled into a plain of sand and gravel; its alluvial soil has been washed into the Nile, which has transported it a distance of several hundred miles to fill up the morasses and form the Delta of Egypt; its rivers have been either dried up or submerged; and where man has not abandoned it, he has degenerated to the level of a savage.

Treachery, dishonesty, and drunkenness characterize the men, and vulgarity and licentiousness the women. The Bishareen are dishonorable, faithless, and vicious, say Khunzinger, Malte Brun, and McCulloch. Many of them are worked as beasts of burden to tow the boats on the Nile. Both sexes go naked, and the money of the country is a sort of broom-corn, called *dourra*.

Gold has been found in nearly every region tributary to the Nile, from the equator to the first cataract. The following is a summary of those regions too distant or too unimportant to be connected with the supply of water or the integrity of the great river channel of Egypt:

Curzon says that in the 'fifties he met at Assouan a European from the mountains beyond Darfoor; this man showed him several iron-bound chests full of gold from that region. Some of the gold was in nuggets, but most of it was in the form of rings the size of bracelets, and others of the size of large heavy finger rings, all of pure gold. These rings were passed in Darfoor as money and were of the exact form of those used for the same purpose by the ancient Egyptians and of the rings or bangles found in ancient Celtic and British countries.

Kordofan lies between Darfoor and the Nile. It abounds with auriferous placers, which were washed by slaves. The trade in gold was formerly monopolized by the Pasha; when gold was sold clandestinely at the rate of \$8 in silver for 430 grains of fine gold, equal at the old rate to \$17.30 per oz. Troy, or about 15% under the mint value.

The Takale district, on the west bank of the White Nile, in the Kordofan country, Lat. 12° N., is spoken of by Pinkerton as a placer country. At Luca, apparently in the same district, as well as at Sheiban, gold, probably gold dust in quills, is the only money.

Albuquerque, a Portuguese commander, gold-hunter, and pirate, landed on the Coast of Abyssinia about the year 1510, and at once proceeded to ransack the country for gold. Among the means that he employed, was to enslave the living, and plunder the graves of the dead. His rapacity and cruelty left so strong an impression on the natives down to a very recent date, that the use or possession of gold was strictly forbidden in the kingdom of Shoa. The monopoly of the gold trade by the sovereign of that country may have something to do with this interdict. The Suakin merchants deal in gold brought from the Fazooglu country, on the Blue Nile, which is in latitude 11° N. In October, 1838, Mahomet Ali left Cairo in a steamboat to visit this region. The mines proved to be near the confluence of the Blue Nile and the Fazangoro. After inspecting them, he left a colony to work them for wages, and laid the foundation of a town near-by, to contain 1,500 families; but the mines failed to pay, and the workings have gone to ruin. The previous productiveness was due to the fact that they were worked by slaves, who were paid nothing for their labor but blows and a scant living.

In the Kaffa country south of Abyssinia and in Lat. 7° N. gold used to be found so plentiful that it was not

much dearer than silver. But all this has changed since the railroad reached Khartoum.

Adowa is in Abyssinia about 50 miles from the Takaze and in Lat. 14° N. Gold is one of the principal articles of the transit trade through this place and of the export trade from Abyssinia generally. Some of this gold probably comes from the Kappa country. Cosmas, a Greek trader, who visited Ethiopia (Abyssinia) about A. D. 535, gave an account of this trade, which in his time appears to have centred at Axum, the capital. The gold came from a country called Sasu.

Strabe, while describing Meroe, says: "There are also mines of copper, iron, gold, and various kinds of precious stones." This reference is applicable not merely to Meroe, which is an alluvial plain containing no gold mines, but to the whole of Nubia. The mention of gold mines in connection with Meroe may have been derived from the fact that Shendy was a mart for the gold of the Upper Nile regions. It is so still.

There are no gold mines below the cataracts. The first or lowest cataract is in Lat. 24° N., and this, therefore, is the northern limit to the gold mines of Egypt.

The above list comprises all except the Bisharee gold mines in the valley of the Nile from the 11th parallel, which may fairly be regarded as the extreme southern limit of Egyptian authority, to the 24th parallel, north of which no mines have been found. Besides the gold mines of the Nile valley, there are numerous others in the surrounding countries, other than those mentioned by Herodotus, in Thalia, which are supposed by Rawlinson to have been in the Somali country. This is on the south coast of the gulf of Aden. At the present time there are some small lots of dust shipped from Leila and Berbera. There are gold mines, also, in the Kaffa country previously noticed, and others in the Coast range of the Red Sea.

We now come to the principal gold region of Egypt, and the greatest of all antiquity. The principal gold mining district of antiquity was in the Bisharee country, situated in the great Nubian bend of the Nile, between Lat. 20° and 22° 40' N. and Long. 32° 30' and 35° 20' E. In the Pharaonic period, the produce of these mines was sent down the Nile; the shipping port being Edfou, or Epollinopolis Magna, or Redesiab, in Lat. 24° 53'. It was ten days journey northwest from the mines. Opposite to Edfou was Bahayreh. In the Ptolemaic period the shipments were to various ports on the Red Sea, among them Berenice, Lat. 24° N., a distance of about 260 miles from the most productive mines. This place is now a mere ruin. The southern extremity of the Bisharee country is below the 3rd cataract; while its northern extremity extends to half way between the 2nd and 1st cataracts.

The Bisharee country forms the foot-hills to the sierras of Abyssinia, which are 12,000 to 15,000 ft. above sea-level, the highest of the hills being about 6,000 ft. in altitude. They gradually diminish until they meet into the plains of Egypt.

According to Linant de Bellefonds, there were gold mines at about twenty places in the Bisharee region, the uncouth names of which we omit.

Next to the mines of the Altai mountains in Asia the Bisharee mines of Egypt are probably the oldest in the world; and in view of the supposed East Indian origin of the Egyptians, and the distant researches and conquests which have been made by the leading nations for the acquisition of gold, it seems not at all improbable that there existed a close connection between the discovery of the Egyptian mines and the settlement of the country by Asiatic races. At what era this occurred cannot be determined with any approach to certainty. If conjecture be

admitted where dates are uncertain, it appears likely that the Bisharee mines were worked as early as the era of Menes, which is variously assigned to from 16 to 19 centuries B. C., for in the time of that monarch the Nile was diked, and from the character of this river and its surroundings there could have been no necessity to dike it until mining had surcharged its waters with sediment.

That Menes was an Indian conqueror and lawgiver; that the Indian code of Menu, still extant, and assigned variously to from the 16th to the 21st century, B. C., is evidently re-compiled from an older code, now lost; and that commerce between India and Egypt existed from the remotest times mentioned in history or derived from archaeological remains, are some of the facts that support these dates.

However this may be, the Bisharee mines are known to have been worked for quartz so long ago as the 15th century B. C. From the fact, understood by every miner, that quartz is never worked as long as the placers are profitable, and judging from the experience of Italy, Spain, and Brazil, where equally extensive placer deposits were worked, as in Egypt, by the hand-labor of slaves, the Bisharee placer mines were at least 200 years old when the quartz was worked during the 15th century B. C. This carries the era of their discovery back to the 17th century B. C.; and they may be even older.

The next date at which these mines are known to have

of people. For the Kings of Egypt condemn to these mines not only notorious criminals, captives taken in war, persons accused of false dealings and those with whom the King is offended, but also all the kindred and relatives of the latter. These are sent to this work either as a punishment, or else that the profit and gain of the King may be increased by their labors. There are, thus, infinite numbers thrown into these mines, all bound in fetters, kept at work night and day, and so strictly guarded that there is no possibility of their effecting an escape. They are guarded by mercenary soldiers of various barbarous nations, whose language is foreign to them and to each other, so that there are no means either of forming conspiracies, or of corrupting those who are set to watch them. They are kept to incessant work by the rod of the overseer, who besides, lashes them severely. Not the least care is taken of the bodies of these poor creatures; they have not a rag to cover their nakedness; and whoever sees them must compassionate their melancholy and deplorable condition; for though they be sick, maimed, or lame, no rest or any intermission of labor is allowed them. Neither the weakness of old age, nor the infirmities of females excuse any from the work, to which all are driven by blows and cudgels; until, borne down by the intolerable weight of their misery, many fall dead in the midst of their insufferable labors. Deprived of all hope, these miserable creatures expect each

In the Nubian Desert.

On the Road to the Nile Valley.

been worked is under Thutmes III of the 18th dynasty; Seti Sethos, or Sethosis of the 19th dynasty, and Ramses or Rameses II; son of Sete. All these dates are derived from inscriptions on the neighboring rocks and temples and possess the highest archaeological value.

The vast sum of silver and gold that is said to have been contained in the treasury of Rhamsinitus, a monarch whose era is attributed by Rawlinson to the 18th dynasty, points to the working of the Bisharee mines for gold and commerce with India for silver. The quantity of gold among the spoil carried away from Egypt by Cambyses, about B. C. 526, part of which was regained by Ptolemy Euegetes B. C. 346; the extent of the tribute imposed by Darius, which was 700 talents besides 7,000 talents worth of corn and the produce of Moeris and the annual revenues of Ptolemy Auletes, the father of Cleopatra, which were 12,500 talents per year, imply—if these treasures are meant to be expressed in gold—the production of this metal upon a large scale.

In B. C. 50 the Bisharee mines were visited by Diodorus Siculus. He says: "On the confines of Egypt and the neighboring countries there are regions full of gold mines, whence, with the costs and pains of many laborers, much gold is dug. The top soil is naturally black, but in the body of the earth there are many veins of shining white quartz, glittering with all sorts of bright metals, out of which, those appointed to be overseers cause the gold to be dug by the labor of a vast multitude

day to be worse than the last; and long for death to end their griefs."

During recent times the Bisharee mines were visited by Mahomet Ali, Belzoni, and Linant de Bellefonds; the first of these reopened and worked some of them for a short time, but without success.

TUCKED away in an editorial article on the transmutation of metals in the *Independent*, is a statement which, if true, should influence powerfully the imagination that has lately played over the phenomena of radium. "That we may be able some time to reverse the process [the breaking down of atoms]" says the writer, "and change lithium into copper and copper into gold, is conceivable, but if possible it would not be profitable, because the amount of energy necessary to be absorbed to effect the transmutation would cost more than the gold produced." The alchemy toward which science was just groping, thus turns out to be an industry that could never hope to pay dividends. Instead of the unimaginable enrichment of the inventor, or the utter demoralization of values predicted by various romancers, the actual making of gold from a base metal will be a mere laboratory curiosity, considerably less entertaining than Prince Rupert's drops. We can even foresee the philosopher's stone being peddled about Wall Street in the hopeless search for a banker willing to underwrite so useless an invention.—*Evening Post.*

Lining for Tube-Mill.

The use of silex for lining tube-mills has been discarded at the El Oro mill, in Mexico, and in place of it bar plates, made of cast iron, are employed. See accompanying drawing and photograph. This device has

Fig. 1. Bar Plates for Lining Tube-Mill.

proved most successful. During the revolution of the mill the pebbles are hammered by each other into the recesses between the bars or ribs, and thus a kind of silex lining is formed. The pebbles lodge there very firmly indeed and wear down almost to the one-inch web. This

Fig. 2. Bar Plates.

is also allowed to remain until it is completely worn out, just as in the case of the ordinary flat cast-iron liner, and, naturally, at very much less cost. The plates are made of such lengths as to best suit the bolt-hole spacings of the mill. The use of the more flinty portions of the ore as grinders was not a success.

GYPSUM IN CANADA.—Gypsum occurs in New Brunswick, near Hillsboro, Albert county, and in Ontario, where it is exploited principally along the valley of Grand river from Paris in Grant county to near Cayuga in Haldimand county. Extensive, but undeveloped gypsum beds occur also along Moose and French rivers, near James bay; and in Nova Scotia thick beds of gypsum occur near St. John harbor, Port Bevis, and Baddeck bay. A large deposit of gypsum occurs on Manitoba lake.

The Camp Bird Mine.

This splendid gold mine, near Ouray, Colorado, has proved one of the best speculative enterprises in which English money has been placed. The property was bought from Thomas F. Walsh in 1902, the price being \$5,300,000, mostly cash. The annual report just issued shows that for the twelve months ending April 30, the mill crushed 38,295 tons of dry ore, giving a gross value of \$1,273,475. The gross earnings during the period were \$1,341,513, and operating expenses \$416,201, leaving net earnings for the year of \$925,312.

The detailed statement gives the results of operations, which shows an increased cost of nine cents per ton, due to a lower ratio of concentration; on the other hand, mining costs show a decrease due to less ore having been broken down. The operating results, however, have been satisfactory in view of the difficulty that has been encountered in securing labor.

The total amount of development work undertaken was 2,997 ft. In the report William J. Cox, the general manager, states the result of every foot of exploration in the various parts of the mine, the nature of the development being indicated by statements as to 'pay-ore,' 'no ore,' and 'country rock.' In this way the stockholders can see at a glance how the mine is being opened up.

"During the past year," says the report, "there was expended \$26,562 in construction work. The operations during the year have confirmed the estimates given in the last annual report. A careful and conservative estimate of the present ore reserves shows: Broken ore reserves of 112,000 wet tons which will yield a net profit of \$1,850,981; unbroken ore reserves of 89,000 wet tons which will show a net profit of \$1,736,906.

"The total net profit to be derived from the ore reserves is estimated at \$3,500,000, a decrease of \$800,000 as compared with the net value of the ore reserves shown in the last annual report. The reserves have decreased in a large part due to the fact that the company has been unable to carry out development work as vigorously as it had wished to on account of the shortage of labor, and also that our development work has only been carried on during about half of the year.

"The new plant, which started operations on November 1, 1906, was rapidly built, and is now running satisfactorily. It was built for less than the estimated cost, and also within the estimated time mentioned in the last annual report."

The results of the operations during the last five years are shown in the table below:

Year ended April 30	Gross earnings.	Profit at the mine.
1903.....	\$1,976,289.68	\$1,233,007.42
1904.....	1,923,911.74	1,217,783.56
1905.....	2,342,361.45	1,656,301.54
1906.....	1,910,567.93	1,231,864.68
1907.....	1,341,513.99	925,312.55
Total for five years.....	\$9,494,634.79	\$6,324,269.75

From the ore treated during the year an extraction of 95% of the gold contents has been obtained, yielding \$34.99 per ton. The manager reports that, exclusive of depreciation of plant, the cost was \$7.69 per ton, of which amount 67 cents is for taxes. There was, in addition, \$1.56 per ton expended in development.

The report shows that the ore reserves have decreased to 201,000 tons, as compared to 210,920 tons in 1906 and 231,497 tons in 1905; concurrently the estimated profit on these reserves has decreased from £993,853 in 1905, to £881,117 in 1906, to £717,213 in 1907. Developments in depth have proved disappointing.

Attachment Between Rope and Sinking Bucket.

Written for the MINING AND SCIENTIFIC PRESS
By CHAS. B. BRODIGAN.

During the sinking of the deep-level shafts on the Brakpan Mines, Ltd., in the Transvaal, a lot of trouble was caused by the sinking-bucket developing a tendency during the hoist to swing violently and foul the shaft-timbers. This trouble has been experienced in practically every deep-level shaft sunk by the aid of buckets, as distinct from skips, and it generally occurs at a depth of 1,700 to 2,500 ft. The reason for the swing is hard to determine and perhaps, when found, possesses but an academic interest. The writer decided that looking for reasons was a vain pursuit, and that the swinging was a necessary evil; the only thing to do was to shorten the connection between the rope and the bucket and so prevent the swing attaining a dangerous amplitude.

To accomplish this shortening, the 'capping' shown in Fig. 1 and 3 was designed and made. It has now been in use for four months without the slightest trouble being

claim made for it is, that applied to hoisting ropes, it satisfied all that was required of it.

In order to illustrate the shortening that was effected by using the new capping, a sketch of the ordinary thimble splice attachment, formerly in use, is given in Fig. 2. The new form of attachment can be fixed up in a shorter time than would be taken in making a splice, the actual time taken being 45 minutes.

THE production of roofing slate in the United States in 1905 amounted to 1,241,220 squares (a square covering 100 sq. ft.), valued at \$1,575,000. In 1906 the value of the product was \$5,668,000. Generally speaking, the difference between a shale and a slate is that the former is straticulated parallel to the planes of deposition and the structure is due more or less to the pressure of the overlying material, while slate has more even layers, with a smoother cleavage, and has derived its slaty structure from lateral pressure, the plane being independent of the bedding and at right angles to the direction of the pressure. This makes slate an intermediate

Attachment for Rope of Sinking-Bucket.

experienced from the swinging bucket. The construction of the attachment is clear from the diagrams, and it will therefore only be necessary to describe how the rope is fixed to the cap.

The rope is threaded through the central hole, and then the end is spread and each individual wire cleaned thoroughly. This is best effected by boiling the end of the rope in a solution of caustic soda, and then wiping the wires with a cloth. The clean wires are then dipped in a solution of zinc chloride and into a bath of molten tin. In this manner a coating of metallic tin is given to the wires, which enables the subsequent stopping of Magnolia metal to adhere firmly to them. As soon as the wires are properly tinned, the rope is pulled back until the tinned wires fill the cone of the cap; Magnolia metal is then poured in, and the attachment is complete.

As regards strength, the writer has had a capping tested in the Government Testing Laboratory, and it was found that the rope broke outside the capping, showing that the attachment is stronger than the rope. The idea of this new capping was suggested by seeing the engineer of the testing laboratory using practically the same white metal cone for testing ropes to destruction, and the only

stage between a clay rock, like shale, and mica schist, and slates may be of any age where metamorphism has altered clay rocks to the slate stage. They are generally absent from the Archean, because if clay rocks did exist in that age they have been changed to mica schists; also, they rarely exist in post-Paleozoic rocks, as these have usually not been exposed to extensive metamorphism. The commercial value of slate depends upon the presence of the perfect cleavage. If jointing is too strongly marked in the deposits, too much goes on the dump as waste, as was found to be the case in the Huronian slates in Baraga county, Michigan. Good roofing slate is quite rare, as either it cannot be mined economically, or because the texture is not uniform, the color not suitable, cleavage not sufficiently, or too highly, developed, or joint planes too numerous. A good roofing slate must have only one well developed cleavage, must be massive and strong, of permanent color, and not too brittle to be cut into regular forms. The principal use is for roofing, but it also is valued for slates, strips, flagging, mantels, sills, washbowls, and many other purposes. Pennsylvania has always produced more than any other State, with Vermont second, and Maine third.

The Great Comstock Lode.

Written for the MINING AND SCIENTIFIC PRESS
By G. MCM. ROSS.

The discovery of the Comstock was a natural consequence of the prior discovery of gold in California. From the eastern slope of Mt. Davidson in the year 1850, it was possible to see the trains of emigrants moving westward. Those who had learned the limit of physical endurance of man and beast rested after their weary march across the desert before undertaking the crossing of the Sierra Nevada, the last barrier between them and the land of gold. The young and vigorous men discovered that their camp was made in a plain below a splendid mountain range that could be reached between two canyons, one to the north, the other to the south.

These gulches led to the Comstock, and they were natural concentrators of the metals removed from the outcrop of the lode by erosion. The most northern gulch forked within two miles of the lode, forming the Six Mile and Seven Mile canyons. Six Mile ends at a point just below a massive outcrop; at the end of it, free gold and silver sulphides were found by prospectors on June 8, 1859. Prior to this date the placer miners had followed the gold up through Gold canyon, through the present site of Silver City up to Gold Hill, so that by 1859 the Comstock lode had been reached from both sides.

The value of the silver sulphide was not discovered at once as it was an unknown black metal to all of the prospectors. When the value of this ore was disclosed silver mining sprang into being and moved forward rapidly. The rich gold and silver ores were shipped to San Francisco, while experiments were being tried on the Comstock and at San Francisco on all sorts of processes and devices for the recovery of the metals. The mining companies themselves undertook the reduction of their ore with an equipment whose magnificence was only equalled by its inefficiency. To this work can be credited the imperfect and costly treatment of the Comstock ores that has lasted until the present day. Shrewd men built mills and as a result of their joint efforts the Washoe process was evolved. When this process had been established as the one best adapted for the reduction of the ore, the profits derived from milling were so large that powerful milling companies were formed and any effort to treat their own ores by the mining companies was effectually discouraged.

The Washoe process is the American form of the Mexican Patio process and is used in the following way: The ore is crushed wet in 5-stamp mortars to a fineness ranging from 20 to 40 mesh; the crushed ore is then settled in square vats on the pan-floor; the finest of the slime is settled in a reservoir outside of the mill. The pulp, after settlement, is charged into fast-running grinding pans holding a charge ranging from one to two tons; the pans are either steam-jacketed or arranged to take live steam into the charge; the ore is kept at such a consistence as, with a motion in the pans, will keep the quicksilver in suspension in the charge. The chemicals used are bluestone and salt. The treatment lasts from three to six hours in the pans, which are finally discharged into settlers (a pan of slower motion, to which large quantities of water are added) to insure the settling of the quicksilver with its gold and silver. The pulp is slowly discharged from the settlers, the quicksilver recovered and strained to secure the gold and silver amalgam, which is then ground in a clean-up pan to remove all impurities, re-strained, and retorted; the resulting crude bullion is melted into bars of fine metal.

The equipment is as follows: For ten stamps of 900 to 1,000 lb. each four standard 2-ton pans are required,

together with two settlers and a slow-motion clean-up pan, retort, assay-office, etc. The actual horsepower required would be 60, but to provide for extra rock-breaking service, or a modification of the process, it is well to provide 75 for the work.

Such a mill will treat from 30 to 40 tons of ore per day at a cost ranging from \$3 to \$7 per ton, depending upon the loss of quicksilver, cost of water, power, etc. In the treatment of the ore such a mill will use 50,000 gal. of water per 24 hours, about 50% of which can be settled and used over again when water is expensive. Plate and battery amalgamation is being used successfully. The free gold contained in the ore is amalgamated and recovered upon silvered copper plates before the ore reaches the settling vats; after passing over these plates the ore is treated by the Washoe process as already described. In ores containing heavy sulphides, it has been found that by removing these sulphides before treating the ore in amalgamating-pans, a higher percentage of the metals is recovered at a reduced cost. Any type of concentrator that will remove the sulphides can be used for the work.

With the Washoe process established, the production of gold and silver bullion from Comstock ores was rapidly increased. In 1860 the yield was gold \$550,000, silver \$200,000; in 1861, gold \$2,500,000, silver \$1,000,000; in 1864, gold \$6,400,000, silver \$9,600,000; in 1869 the output of gold and silver dropped to \$7,405,578; from 1870 to 1877 there was a rapid increase culminating in the last named year with a grand total of \$14,520,614 gold and \$21,780,922 silver, or a total of over \$3,000,000 per month in gold and silver from the Comstock mines. From 1879 to 1895 the output varied from \$7,000,000 to \$1,000,000; from 1896 to 1899 there was a steady decrease until in 1899 the output was less than \$200,000.

The total output of the Comstock in gold and silver to the end of 1902 is close to \$371,000,000; of this sum there was about 60% silver and 40% gold. Besides the amount thus recovered, the losses are estimated at about \$60,000,000 and \$80,000,000, respectively, of which modern methods would have saved 70 per cent.

The discovery of the silver sulphides having been made by placer miners it was some time before the nature of the lode was understood. The first ore was found in small westerly dipping veins that connected with great masses of ore; these turned when nearing the easterly dipping foot-wall, the main fissure following this wall to a depth of 3,200 ft. below the surface. The great riches of the Comstock created intense excitement throughout the world, so that in a short time every country was represented on the spot by men interested in some phase of mining. Added to them were the speculators and gamblers. The result of their combined efforts was to cover the surface of the earth with hundreds of mining locations, for the speculators and gamblers soon discovered that mining claims had a speculative value. The main lode was soon outlined and reduced to ownership by many companies.

The high wages that were paid to the miners and mechanics attracted the most skillful of these men from the ends of the earth. The managers were thus enabled to meet the unusual difficulties of mining large bodies of ore, handling large quantities of water, and opening up new ground where the temperature was unusually high. All of these difficulties were fairly met. The quartz miners of the Comstock had penetrated the lode to a depth of 3,000 ft. within 20 years of the discovery of silver sulphides on the surface. Within that time the simple hand-windlass had been superseded by more and more powerful machinery until direct-acting hoisting engines of 1,000 hp. were being used. These engines were de-

signed for work to a depth of a mile below the surface. An adit (the Sutro tunnel) was started and connected with the lode from a point in the valley of the Carson river four miles distant, thus forming a new base of operation 1,600 ft. below the surface. Powerful pumping machinery was installed at various points.

During these years of intense activity the Comstock mines were controlled by individual owners or by small numbers of men with headquarters at San Francisco. The properties were irregular in size and in the number of shares that represented them. The stock of these mines was regularly bought and sold, so that the controlling ownership often changed; but the policy of those in control was always the same: to make the most money possible out of the mines in the shortest possible time, either by manipulating the stock, or by working the mine, or by both. While the management of the mines was generally capable, the spirit of the gambling speculator dominated the situation, and when, after a splendid dash at attaining great depth the workings were threatened with hot water, a retreat was ordered and 1,700 ft. of partially developed ground was abandoned. The reason for this was the fact that no unity of interest had ever been acknowledged by those in control of the various mines on the Comstock, and even science failed to give a reasonably definite statement of what might be expected in depth.

As a vertical depth of 3,300 ft. was reached before the lower levels were abandoned, it was several years before the water again rose to the level of the Sutro tunnel. During these years many millions of dollars were extracted from orebodies that formed the margins of the old bonanzas. It is one of the remarkable features of these orebodies that they begin and end in quartz bodies, quartz being the matrix in which the ore is found, forming a central core or lens surrounded by low-grade quartz. During the mad rush to extract rich ore the heart of the bonanza was literally torn out of its quartz body and in every instance where a bonanza was mined it has paid to work the ground again. It is also true that in several instances a greater tonnage was extracted during the second period of mining than during the first, even when it was not possible to explore the ground thoroughly. Had a more conservative and rational system of mining been adopted, there can be no doubt that many of the Comstock mines would have continued to pay dividends for many years, and that the bullion production would have been much greater.

By the year 1898 the condition on the Comstock was nearly hopeless. Many of the mines were abandoned; ruin and decay were prominent. At this period a few men succeeded in getting together the loose ends of the many interests and in convincing those in control of them that to save the Comstock from complete abandonment a united effort must be made to recover the lower levels of the lode. They were so far successful that a provisional and temporary union of all Comstock interests was formed by 28 mines forming the Comstock Pumping Association. The operations of this Association were successful.

The device used for draining the mines is a modified hydraulic elevator designed to work under a head of 2,000 ft. and over. Using water under such great pressure brought forward problems in hydraulics that are not yet solved. Before \$100,000 had been expended more water was discharged into the Sutro tunnel than had been discharged by the \$5,000,000 worth of pumps formerly in operation. Shortly afterward it was decided to operate the mines by electric power. A company was formed that secured contracts for power paid in advance of delivery and the power plant was built. The plant is now in

successful operation delivering power that is used in mining, pumping, milling, and lighting from a generating station at a point on the Truckee river 33 miles distant from Virginia City.

Of late years there have been no startling developments on the Comstock. The discovery at Goldfield and mining through Nevada, generally, has served to hold the attention of the speculative public, to such an extent that the Comstock has nearly escaped notice. But recent developments to the west and south of the Comstock may serve to attract attention to the famous lode. At Silver City, an important discovery has been made, undoubtedly the result of patient effort, for Silver City has been self-supporting for many years, and judging from the appearance of this camp at the south end of one of the branches of the Comstock lode, Silver City looks as though it could sustain itself without assessments for some time to come.

Encouraging prospects have been found in American Flat, the south branch of the lode; these, if developed, will undoubtedly revive interest in a number of mines that have been practically abandoned for years. Just west and south of American Flat, there are excellent copper prospects that have not been developed, probably because they are so near the Comstock.

The only change in the Gold Hill mines is the change of management at the Yellow Jacket. The new managers are building a large concentrating mill to work the dumps and the ores that are known to exist in the mine, but to be successful they must add a cyanide plant to their concentrating works. At the Ward Combination shaft, there is a struggle between hot water, hot air, and human endurance to get below the 2,560-ft. level. At this shaft, interesting, and what seems to be satisfactory, results were obtained with a light Starrett pump. A station is being opened on the 2,400-ft. level to install one of the series of powerful electric-driven piston-pumps on hand at the Ward shaft. Extensive repairs are being made in the Sutro tunnel. Encouraging developments have been made from the Sutro Tunnel level in the Hale & Norcross and Savage mines. Work is being planned for the Best & Belcher on the tunnel level. Tributaries are still able to find ore in the Chollar Croppings. North of the Con. Virginia, all the work is confined to the east vein (which has yielded all the ore extracted since 1904) or a search for it, and no work is being done on the main lode.

To the Butters plant there has been added a modern 20-stamp mill, with table and belt concentrators, sizing devices, and tube-mills for re-grinding the coarse tailing before cyanidation. The Comstock now possesses a complete modern reduction plant that can recover at least 90%, but, unfortunately for the Comstock, this modern mill is not treating the output of the Comstock but outside ores from Tonopah that are delivered to the mill from the Virginia & Truckee Railroad by an aerial tram.

Work in the long tunnel driven into Mt. Davidson by the Hale & Norcross has been temporarily stopped at a very interesting point; there is a good stream of hot water now flowing out of the adit from a westerly dipping formation. The latest geological work on the Comstock, in which appears an account of the formation passed through by the Hale & Norcross tunnel, is given in John A. Reid's paper 'The Structure and Genesis of the Comstock Lode' published by the Department of Geology of the University of California. It is to be hoped that work on the Hale & Norcross tunnel may be resumed and the adit extended at least 1,000 ft. farther west and that the work now being done to the east of the main lode will serve to attract such attention to the main lode that rational development work will be resumed.

Rapid Hoisting With Light Equipment.

Written for the MINING AND SCIENTIFIC PRESS
By GEORGE A. PACKARD.

The visitor to the zinc-lead district of southwestern Missouri, who is accustomed to the almost continual ringing of signal-bells in the shaft-houses of the West, is struck with the quiet system, and wonderful rapidity with which the hoisting is accomplished at some of the mines in the vicinity of Joplin. For those unacquainted with the district it should be said that the ores occur in beds of limestone and chert, lying nearly horizontally, and rarely at a depth of over 400 ft. Until within a few years mining was confined to the pockets of richer ore and was done almost exclusively by lessees. As the lessees also operated their own mills, the mining and milling machinery was naturally rather crude, being constructed with a view to small first cost and possible removal.

With higher prices for spelter has come the development of large bodies of low-grade ore in the 'sheet ground,' company management, and larger daily production from a single shaft. Yet hoisting with a bucket, or 'can,' as it is locally termed, continues to be the usual practice, though the mill has a capacity of 400 tons or more. Perhaps one reason for this is found in the fact that the mills are placed close to the shaft so that no tramping of the ore is necessary after hoisting.

The hoist at the plant of the American Zinc, Lead & Smelting Co., and the results attained, may be considered as typical of the advanced practice.* The hoist is driven by a vertical engine having a single cylinder of 8 in. diam. and 7-in. stroke, under 120-lb. steam, using a double exhaust. The cast-iron pinion commonly furnished is replaced by one of rawhide, giving longer life to the gears. The single drum, loose on the shaft and driven by a clutch of the band type, is 18 by 18 in. as furnished, but is lagged up to 24 in. diam. This machine is hoisting from a depth of 320 ft., and I saw the round trip made in 42 seconds. This speed is kept up for long periods, and I was told by the manager that 620 buckets had been hoisted through the single-compartment in a 10-hour shift, of which three-quarters of an hour should be deducted for dinner. This means an average of 67 buckets per hour, or more than one each minute for an entire shift. To accomplish this only two men are necessary. The buckets, which hold from 850 to 1,000 lb., are delivered by the trammers to the station at the level. One man does all the work here. He pushes the first full bucket into place; the empty is dropped and detached; the full one is hooked on and hoisted. Before the latter is dumped and lowered the empty has been delivered to a sidetrack, from whence it is taken by the trammers, and another full bucket is ready.

On top, the hoisting engine is placed close to the line of the shaft, though at a considerable distance above the ground in order to gain dump-room. The engineer stops the bucket, hooks on to the bottom, and dumps it in the usual manner. He then detaches the hook, lowers the bucket, and after a few seconds starts hoisting again. No signals are given. The engineer simply waits what he knows is a proper time for the empty bucket to be replaced by a full one at the bottom. Then he raises the bucket about six feet, holds it for a second while the man below stops the swinging and gets it in line with the vertical shaft, and hoists as rapidly as possible to the top. The speed of the rope reaches 1,250 ft., and averages 1,100 ft. per minute. In spite of this speed the bucket is almost invariably stopped at exactly the point for attaching the dumping hook. The entire leeway between the top of

the well and the sheave is only 10 ft. Of course, signals are used in handling men, timbers, and supplies; and the hoist is made extremely small, and with abnormal wearing surfaces, to stand this service.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

H. W., of Paris, Cal., sends a piece of Chalcedony.

The specimens sent by T. L. G., of St. Louis, have not been received.

Two Chalcedony pebbles were sent by F. A. F. of Tehachapi, California.

B. W., of Challis, Idaho, sends a specimen of Limonite, the hydrous oxide of iron.

The specimens sent by C. W. E., of Ashland, Ore., are: No. 1 and 3, Carbonaceous Shale; No. 2, Chlorite and Clay.

A specimen of Limestone containing small pyrite crystals was received from S. S. S., of Winthrop, California.

The specimen from Bearmouth, Mont., marked J. S., is rock stained with the red oxide and the green carbonate of copper.

The specimens from Pasto, Porto Rico, marked M. L. M., are: No. 1, Diabase with copper oxide stains; No. 2, Chloritic rock; No. 3, specular Hematite.

The specimen from Girdwood, Alaska, marked G. D. H., is a basaltic rock containing crystals and streaks of pyrite which may carry gold or copper. An assay is necessary to determine its value.

The samples sent by M. C., Silver Hill, Ariz., are: No. 1, Quartz, Feldspar, Garnet, and Pyrite; No. 2, Quartz and Feldspar with specks of bornite and chalcopryrite; No. 3, an altered volcanic, apparently a rhyolite; No. 4, Hematite in garnetiferous rock; No. 5, amygdaloidal Andesite with a copper phosphate, probably Libethenite; No. 6, altered Porphyry stained by hematite; No. 7, Quartz Porphyry.

The large share which manufactures form in the exports of the United States to all parts of the world except Europe is shown by an analysis just completed by the Bureau of Statistics of the Department of Commerce and Labor. These figures show that manufactures formed 86% of the exports to South America in 1906, 85% of the exports to Oceania, 75% of the exports to Asia, 66% of the exports to Africa, 62% of the exports to North America, while even to Europe manufactures formed 27% of the total domestic merchandise sent in the fiscal year 1906. This general group, 'manufactures,' upon which the above percentages are based, includes both manufactures ready for consumption and manufactures for further use in manufacturing. The first group includes all manufactures in the fully completed form and ready for immediate use. The second is made up chiefly of chemicals, leather, naval stores, lumber, copper in pigs, bars, and ingots, and various grades of iron and steel which have passed through a process of manufacture but are to be further used in manufacturing, such as steel bars, billets, ingots, blooms, sheets and plates, tin plate, wire rods, and pig iron.

* The hoisting-engine is of the type made by the English Iron Works Co., of Kansas City.

Transport of Machinery in Mountainous Countries.

Contributed by H. H. KRESS, of the A. S. Cameron Steam Pump Works.

American capital is being constantly invested in many

Burros on the Trail.

promising enterprises throughout Mexico, Central and South America. Only recently, the U. S. Consul General at Mexico City estimated that during the last four years \$125,000,000 of American money had been invested in the

mines of Mexico alone, while in other industries the investments are also very large.

The greatest percentage of capital, however, is invested in the mining industry; as, indeed, it was owing to the discovery of precious metals in the various parts of these

ous districts, there are still a large number of mining camps without close railroad facilities; and in some places, the settlements are many miles from a railroad. Transportation is costly and the methods, in many places, are crude: in some parts, merchandise and machinery are carried only on ox-carts; although in western Mexico, the burro or donkey is a most important factor, and is preferred on account of being quicker and safer in the dangerous mountain passes. Thus the traffic between the railroad and the interior is largely done on burro-back. These little animals are worth from \$12.50 to \$20 apiece. They average about 500 lb. in weight and will carry up to 300 lb., traveling from 20 to 40 miles per day, according to the condition of the country.

The machinery used in these mining countries is often specially built to suit this mode of transport; and it must be designed and built to allow for dismantling, so as to form a load of moderate weight for an animal to carry.

We give herewith two illustrations of mule-teams loaded with sectionalized Cameron pumps; also illustration of one of these pumps as it appears when put together. This type of pump has been adopted almost exclusively for the mountainous regions, and has found its way on mule-back and some-

times by more primitive modes of transport, over the mountain passes and terraced ranges of our own country and old Mexico, Colombia, Peru, and Chile, as well as into other mining regions of Central and South America.

These Cameron pumps are built for the heavy work and rough service to which they are usually subject in mining work. They are built in sections, the parts being so designed and proportioned that the pumps can be taken apart at the bolted joints, and packed for shipment. The majority of pieces weigh less than 150 lb., while the maximum weight, 300 lb., is rarely found, and only in the larger sizes. The parts are so arranged and marked that they can be readily assembled and the pump set up without the aid of a skilled mechanic; and every pump that leaves the Cameron works at New York is thoroughly tested to a degree far in excess of its rated capacity. The Cameron shipments from New

Vertical Plunger Sinking Pump, 'Sierras Pattern.'

Pack Train Carrying Mining Machinery.

countries that settlers were led to exploit other resources; thus, new mining camps, and towns were created and are growing rapidly with the new industries. This industrial development makes a constant demand upon machinery and equipment, the larger portion being supplied by American manufacturers. In the interior and in the mountain-

York, destined for long journeys, are arranged for convenient handling, being strongly and securely boxed, on account of the numerous transfers of freight in steamship and railroad traffic before they reach their destination. The arrangements for mule-back transport must usually be made at some convenient station on the line of a railroad or other carrier.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

PERCOLATOR. No. 866,985; Charles E. Trehwella, Forestville, Conn., assignor to American Silver Co., Bristol, Conn., a corporation.

In a percolator, the combination of a cup having a perforated central overflow tube extending upwardly from its bottom and provided with a contracted tip at its upper end, with a fountain tube of a smaller diameter than said overflow tube and extending upwardly through the said overflow tube and its contracted tip, the smallest diameter of which is approximately the same as that of the said fountain tube, and a finely perforated retainer fitted to the upper part of the said cup and overflow tube, the perforations in which tube permit an excess of liquid to flow from the retainer into and down through the said overflow tube.

ROLLER-MILL. No. 866,799; Edgar S. Moulton, Central City, Colorado.

In a mechanism of the class described, the combination with a supporting frame, of a lower casing positioned within said supporting frame, a drum carried by said supporting frame, said drum provided with a plurality of flanges upon each side, removable bands secured to said supporting frame and positioned between the flanged portions of said drum, and an auxiliary wheel positioned within said drum.

HYDROCARBON ROCK-DRILL.—No. 863,646; John V. Rice, Jr., Edgewater Park, N. J., assignor of one-eighth to Albert Edward Tower, Poughkeepsie, N. Y., and seven-eighths to Fred E. Tasker, New York, New York.

In a rock-drill, the combination of a cylinder, a piston therein, a piston rod having a movement with the piston and a secondary movement inside of the piston, means carried by the piston for imparting a rotation to the rod, and elastic means connecting the piston and piston rod, consisting of a yielding rolling device on one element engaging a curved face of the other

CENTRIFUGAL HIGH-PRESSURE PUMP.—No. 865,504; Carl Lager, Baldwinsville, New York.

In a series-runner centrifugal pump, a series of separate annular case-sections one for each runner and means securing them end to end, each case-section having an annular waterway arched transversely, separate circular diaphragms interposed between and held by the meeting faces of the case-sections dividing the interior of the case into runner chambers and each provided with a water-passage leading from its periphery inwardly through one of its end faces, and a runner in each chamber having its inlet communicating with the waterway in one of the diaphragms and its outlet opening into the waterway of its case-section, said runners having their inlet openings all facing in the same direction, and an external conduit connecting the waterway of one of the case sections with the inlet side of one of the runner chambers and discharging against the inlet side of the first runner of the series.

CRUSHING-MACHINE.—No. 863,833; Morton G. Bunnell, Chicago, Ill., assignor to The Western Wheeled Scraper Co., Aurora, Ill., a Corporation.

A crushing machine, comprising a stationary jaw, a movable jaw arranged to oppose said stationary jaw, a pitman actuated at its lower end by an eccentric device, a swinging yoke having one end connected with the stationary jaw and the other end connected with the upper end of said pitman, and a toggle joint connection between the movable jaw and the upper end of said pitman, said connection consisting of an arm rigid with the movable jaw but pivotally engaging the pitman, and the toggle joint being adapted to break joint both above and below the centre during the up and down movements of said pitman.

SECTIONAL DREDGER-BUCKET. No. 866,971; Harley L. Sherwood, Oakland, California.

An excavating bucket provided on the outside of each of its narrow sides with a keel to cause the bucket to automatically recover its operative position when tilted

Editorial.

THE CALIFORNIA MINERS' ASSOCIATION will meet in annual convention on November 25 in San Francisco. The official call appears on another page of this issue.

IT WILL shortly be known that Mr. Hammond has resigned his position as advisory engineer to the Guggenheims. This step, we regret to say, is due in part to ill health. Mr. Hammond will go to Santa Barbara for the winter. It is most likely that he will be succeeded by Mr. Pope Yeatman. At the same time we have reason to know that Mr. A. C. Beatty will shortly sever his connection with the Guggenheims and become associated with Mr. R. D. Evans of Boston.

CYANIDATION is being used on an increasing scale in Nevada. We take pleasure in publishing an excellent article on the new mill built at Millers, in Nevada, by the Tonopah Mining Company. The author is the superintendent, Mr. A. R. Parsons. The plant was erected by a San Francisco firm, C. C. Moore & Co., with Mr. John H. Hopps as consulting engineer. The Desert mill—as it is named—includes the most advanced practice in cyanidation and is said to be giving good results (88 to 90% extraction) on a gold and silver ore of a type not usually considered particularly docile.

AMONG the unreasonable demands of labor-unions is that of the men working on the power plant which transmits electricity from California to Nevada, that is, from the source of energy in the Sierras to the mines at Tonopah and Goldfield. On the California side, where living is cheap and comfortable, the men get \$2.50 to \$3 per shift when engaged in grading for a new unit and in similar work, while on the desert of Nevada, where living is expensive and arduous, they get \$5. A strike is threatened by reason of the demands of the labor agitators that the men in California, who can live for \$15 per month, shall receive the same wages as those in Nevada, whom it costs \$50 per month to meet the bare expenses of living. In fact, the labor union is very much like the metal brokers of the Amalgamated Copper Company; both appear to consider economies a dismal science and unworthy of respect.

IN REFERRING to the apology of the Standard Oil Company as conveyed in a pamphlet of 30 pages, the *Financial Times* remarks that 26 pages are devoted to favorable statements taken from newspapers, and it is amazing that the company "should think the public will regard this as evidence above suspicion." This is fair comment. We are glad to assure our contemporary at London that the public in America is fooled most of the

time, but not all the time, and not by everybody. For instance, the only Californian paper quoted by the Standard Oil in vindication of its piratical methods is a small local sheet of which we never heard before, and having regard to the fact that the press of San Francisco can be subventioned with notable facility, and that the Southern Pacific Company finds it easy to prostitute most of the newspapers of the State, it is manifest that the case of the Standard Oil must be bad indeed.

CALLOUS as Wall Street is to the revelations of predatory finance, the disclosures made in the street railway investigation at New York have proved startling. Not only have enormous sums of money been stolen, but the methods employed have been brazen beyond precedent, even in traction grand larceny. The life insurance scandals look half respectable in comparison; only the deeds of Tweed and his gang afford any parallel. We who live in San Francisco have a traction scandal of our own and if it is on a smaller scale, it is no less mean and sordid. Philadelphia, St. Louis, and Chicago are in a similar plight. No wonder the author of 'The Man of the Hour' laid the scene in "any large city in America," and the time, "today," for whether the audience is in New York, Chicago, St. Louis, Philadelphia, or San Francisco, they feel quite sure, as they see the play, that it must have been written to represent the corrupt conditions obtaining in their own city. The symptoms are not local; they indicate the poisoning of the body politic, with extreme bad health due to an industrial debauch and the intoxication of stock speculation.

Copper.

THE ATTEMPT of the metal brokers of the Standard Oil-Amalgamated coterie to peg copper at a price higher than market conditions warranted, has proved a glaring example of the smartness that is not wisdom and the business shrewdness that over-reaches. These abortive regulators of a world-wide industry are being damned from one end of this continent to another, for to their vagaries is chiefly due the demoralization of the market for copper. Of course, there has been a great falling off in consumption, commencing in March last, but there would have been no such débâcle as we have seen lately if the price had been lowered in accordance with the logic of facts. Instead, an attempt was made to maintain a high price artificially and for a long period. The net result is that copper sells at 13 cents. However, a great deal of interest is now being shown by the actual consumers, and during the past fortnight an increasing business has been done, although the largest consumers have persistently remained out of the market. Evidently, they intend to use the last pound of metal before purchasing, and the longer they can hold off the cheaper they will get their copper, but the moment they enter the market the turning point will have arrived. The Chinese have been buyers of late, and it is estimated that they have purchased some six or seven million pounds altogether. This counts for a great deal in times like

the present, and it may help to prevent further depreciation. It is our opinion that prices have gone lower than was necessary or justified, as usually happens in periods of panic. If we are not at bottom, we are very close to it. The large reduction in production decreed by the Amalgamated and Cole-Ryan interests will no doubt have its effect in due time, say, in three months. W. A. Clark will, we understand, also restrict his output by 50 per cent, and the mines in Sonora are curtailing production, besides scores of smaller companies everywhere. Mines based on 25-cent copper had better be closed down, but companies that can make a profit with the metal at 15 to 18 cents can afford to be patient, and spend the next three or four months in development work and repairs. During the interval the consulting engineers will have a chance to read their accumulation of technical literature, neglected during the boom.

Professional Customs.

IN a recent issue a young mining engineer presented a series of questions relating to the customs usual in professional work, more especially the examination of mines. These questions were made in good faith by one who really wanted to have some guidance in these matters. We published his request for information and then asked a dozen mining engineers to send replies to the ten queries propounded by our young friend. Some of these answers we publish this week, others will appear hereafter.

Obviously some of the questions are elementary, but they are also basic, as involving the rudiments of a professional code. Some of them may be thought unnecessary, but they happen to relate to points concerning which an earnest fellow really wants information, so they have a significance. Frankly, we are glad to ventilate a subject so practical, for assuredly a right code of conduct is as practical a matter as the erection of a stamp-mill or the sinking of a winze. It is not likely that we shall ever have perfect agreement as to the principles at the foundation of the right regulation of professional conduct—that is, ethics. The work done by mining engineers is so diversified, the conditions under which they work differ so widely, the preliminary training of the members of the profession is so unlike, that no one will dare to lay down laws, for who can be the judge? Certainly, not engineering societies of nondescript membership nor college faculties of mixed composition. Nevertheless, as intelligent men, as citizens of more than average education, as members of the community entrusted with more than average responsibilities, we ought to have some notion of the right and wrong involved in our relations to clients, to workmen, and to each other; it may not be possible to study duty as a science, but it is possible to develop ideas that may become second nature, a glorified habit capable of guiding us among the deep waters of finance and the shallows of promotion.

The time was when there were three professions, namely, religion, law, and medicine. These were the 'learned' professions and they ranked immediately after

the army and the navy in social precedence. Even in ancient times the three professional occupations were well recognized. As civilization has advanced in complexity, other professions have been differentiated and the original three have lost some of their primary characteristics. That of religion has become an avocation with some men, to others it is a business; the practice of law has suffered even more, so that while it has continued to enlist the most brilliant minds in all countries, it has also become the tool of every form of wrong doing, until, in this highly developed industrial civilization of ours, the lawyer has become distinguished chiefly for his ability to defeat justice and circumvent the law. The physician, also, although he retains best of all the characteristics we consider professional, has suffered in status, by the admission into the ranks of medicine of the charlatan and the quack, in many cases possessing the less desirable attributes of both the followers of religion and law, as though superstition and chicanery had met and kissed each other. Thus the original learned professions have lost east to some extent, and not only by their own degradation but by the mere number of other so-called professions.

And what is a profession? It is an occupation that involves a liberal education, and mental rather than manual labor; hence it is a calling involving special mental and other attainments or a special discipline. So says the dictionary, and then it adds: "as editing, acting, engineering, authorship, etc." Which is humorous, for editors are born, not made, even if most of them ought to be dead and not living. Actors do not need to be liberally educated, even though the best of them are a liberal education, and as for discipline, the world usually regards them as an undisciplined crew, more akin to the genius of the artist than to the restraint of the soldier. Authorship nowadays is not understood to require special, so much as peculiar, mental attainment; and as for discipline, that is mainly the prerogative of the publisher. However, the main characteristics of a profession are a mental training and a special discipline, that is, the preparation for a specific form of mental labor and a sense of duty. A hod-carrier is a useful fellow, especially in San Francisco at this time, but he is the antithesis of a professional man, because his work requires no previous training, only muscular strength and ordinary willingness to exert it; his work consumes no brain tissue worth mention, for it is distinctly a physical performance; it calls for no recognition of discipline, except that of the walking delegate, which is a rudimentary form of authority; it involves no notions of conduct, it permits him to heave a brick at a tram-car during a strike without loss of self-respect; and it assumes not even the obligation of a contract, for the work of the hod-carrier is measured by the hours spent and not by the work done. In all of the points mentioned, the professional man is, or ought to be, as far as the poles asunder from the useful but ethically simple instrument of industry to whom we have referred.

Such as the hod-carrier is, he meets the requirements of his labor. Little is expected of him in an ethical way—save not to heave bricks at tram-cars—and therefore the possible best hod-carrier is not widely different from the

real man as we find him. In most respects his antithesis is the professional man—the minister, doctor, lawyer, architect, engineer, metallurgist, geologist, and so forth. The ideal hod-carrier is a possibility; the ideal professional man has only to be described to seem a creature too bright and good for this workaday world. He is a man that has received a special training, whether it be at the University or in the wider school of life itself does not greatly matter; he uses his brains, which by education he has made a logical machine capable of difficult thinking; he has undergone discipline and he is under discipline, the discipline of self-respect, of self-control, and of public opinion; he has notions of right conduct, notions implanted in youth and crystallized by contact with his fellows; his work is not measured primarily by the time consumed nor even by the trouble involved, but rather by the excellence of it; he has moral and intellectual faculties, which become developed as he grows older, and he has a tendency to use such faculties in a fixed direction—that is, he possesses character; he has a code, the unwritten laws of a highly civilized human being; indeed the professional man of the highest type has the inheritance of the old aristocracy, expressed in the motto "*Noblesse oblige*"—the compulsion to be honorable. He is the flower of a democracy and the best product of a people whose ideal is an equality of opportunity. "He is"—he *ought* to be. If he is not, it is because he aims too low, or because he has no aim at all, but drifts amid the flux of phenomena we call life. "We never see the target a man aims at in his life; we only see the target he hits."

RED CANYON is the name of a place in Wyoming prominent just now on account of a fiasco in placer mining. Such experienced miners as J. B. and Thomas L. Greenough of Missoula have been sold a salted mine and they are responsible for an ambitious scheme of promotion that has now broken down. It is fair to add that these well known operators have announced their intention to refund all the money subscribed by stockholders. How the gravel was salted is not known. The first samples from 12 pits and shafts yielded from 10 cents to \$9 per yard; on this showing the transfer of the property was made. Later examination and sampling gave no such results. Incidentally we may mention that Mr. Edmund Juessen, of Spokane, wrote to us severely criticising the data given in one of the promoter's reports, but we did not publish his criticism because it did not refer to anything previously mentioned in our columns. Mr. Juessen's inference that a gross blunder had been made, appears now to be fully confirmed. Only yesterday we were also informed that the Red Canyon tract had been offered to San Francisco operators and they had sent Mr. C. H. Munro to examine it. Not satisfied with the high returns obtained from the test pits he had panned the beds of several creeks that cut across the deposit, arguing that in them he would find a natural concentration of the gold, if the average gravel was as rich as stated. He used the sampling of nature to check the tampering of man. When his pannings gave poor results, he advised his clients to drop the business.

Personal.

THOS. H. LEGGETT is here.

J. M. BOUTWELL is at Cananea.

MARK L. REQUA is at Salt Lake.

LIONEL LINDSAY is at Guanajuato.

H. W. TURNER is here from Portland.

H. W. CARTRELL is at Bisbee, Arizona.

JOHN B. FARISH is here from New York.

R. H. BURROWS is in western Chihuahua.

J. L. BOSQUI has gone to Goldfield, Nevada.

E. M. NORRIS, of Salt Lake, is at New York.

L. C. GRATON is in Shasta county, California.

H. DEC. RICHARDS is at the Engineers Club, New York.

W. B. MILLIKEN, of Denver, has gone to Rhyolite, Nevada.

S. F. EMMONS has returned to Washington from Cananea.

FRANCISCO NARVÁEZ, of Pachuca, Mexico, is at Denver.

RENE DE SALLIER, of Atwater, Linton & Atwater, is in Colorado.

ALBERT W. JOHNSTON was married at New York on October 5.

THEODORE DWIGHT was married at New York on September 28.

EDWARD S. WIARD has left Denver to go to Spokane and northern Idaho.

J. NORTON GRIFFITHS has returned to London from Portuguese Angola.

J. D. KENDALL has his office now in Friars House, New Broad St., London.

F. L. BOSQUI has moved from Berkeley to the Crocker Bdg. in San Francisco.

F. H. MINARD, on his return from Cobalt, Ontario, has left Denver to go to Mexico.

C. EVERARD ARNOLD is working in the Smuggler-Union mine at Telluride, Colorado.

JOHN HAYS HAMMOND is expected at Santa Barbara, where he will spend the winter.

B. DRINKWATER is analyst and assistant manager of the La Tortilla works, at Linares, Spain.

E. H. NUTTER has been promoted to superintendent of the Liberty Bell mine at Telluride, Colorado.

C. T. GRISWOLD has been appointed professor of mining and metallurgy in Colorado College, at Colorado Springs.

LEE S. WOOD, of Denver, has been making an examination of the Green Mountain mine near Silverton, Colorado.

J. E. BRADLEY and F. A. SMITH, of Worcester, Mass., have been inspecting the Hercules mine at Silverton, Colorado.

ROBERT HAWTHURST, JR., has been appointed general manager for the Poderosa Mining Co., near Antofagasta, Chile.

O. E. JAGER has left for Australia, having accepted a position with the Great Cobar Copper Co. at Cobar, New South Wales.

H. FORBES JULIAN, of London, England, joint author of 'Cyaniding of Gold and Silver Ores,' arrived in New York on the steamer *St. Louis*.

CHARLES A. CHASE, general superintendent of the Liberty Bell, at Telluride, will move shortly to Denver and open an office as consulting engineer.

GEORGE S. BINCKLEY, manager for the Cia. Metalurgica y Refinadora del Pacifico, at Fundicion, Sonora, Mexico, has resigned, and has been succeeded by E. J. WILSON.

L. W. TRUMBULL has tendered his resignation as professor of mining in the University of Wyoming, to accept the supervision of properties in Sierra county, California. After December 1, his address will be Downeyville, California.

California Miners' Association.

In accordance with a resolution adopted by the Executive Committee of the California Miners' Association, Monday, November 25, has been selected as the date of the annual convention, to be held at the rooms of the California Promotion Committee, on Union Square, San Francisco, at 10 o'clock in the morning.

It is considered of importance that certain subjects of vital interest to the mining industry of the State should be thoroughly discussed, with a view to taking such action as may be deemed necessary. Among the problems of today are the location of mineral claims on forest reserves; the restriction of the area to be located under single ownership; the segregation of timber land and mineral land (especially as it arises at this time in northern California); the damage done by smelter smoke and the relation of the smelters to the mining industry; the work of the Debris Commission as it relates to hydraulic mining in the central watersheds of the State.

As it is expected that the discussions to take place before the Convention will be of the greatest importance to the counties in which mining is carried on, the supervisors of these counties will be asked to appoint delegates to represent them, in case the county has no regular miners organization. The Executive Committee has requested representative men in California to present papers on the subjects mentioned or on other subjects certain to prove of interest to the Convention.

W. C. RALSTON, President.

CHAS. G. YALE, Chairman Executive Committee.

General Mining News.

ARIZONA.

COCHISE COUNTY.

Martin Costello has optioned to Col. L. W. Powell his six claims in the Gleason mining district in the Dragoon Mtn. All the mines at Bisbee have been shut-down the last two Sundays.

The Shattuck-Arizona is still producing about 400 tons of ore per day; half of the ore, the oxidized, goes to the Copper Queen smelter at Douglas while the other half, the sulphide ore, goes to the Old Dominion smelter at Globe. Most of the ore comes from the 700 and 800-ft. levels, although some comes from the low-grade orebody recently found on the 900. The winze in the Leo claim, which is being sunk from the 800-ft. level is still in high-grade ore.—During the past week the Denn-Arizona has slightly increased its shipments. Development work is confined mainly to the orebody found on the 1,000 and 1,100-ft. levels, whence most of the shipping ore is coming. Last week the drift from the Higgin property into Wolverine & Arizona ground was pushed rapidly ahead so as to further develop the orebody which was discovered some time ago. After going through about 40 ft. of good ore the drift broke into an altered limestone formation. It is probable that the drift will be stopped and an inclined winze sunk on the ore.—The shaft at the North Bisbee has been retimbered and the new machinery has been installed. Sinking and driving have begun again. Although the Calumet & Arizona and the Copper Queen Co. have curtailed their output on account of the unsettled condition of the copper market, still the work at the various Superior & Pittsburg shafts has gone on as usual. Most of the output comes from the Cole shaft where the development of the orebodies is being pushed ahead steadily.—At the various Copper Queen properties a good many of the miners have been taken from the stopes and put on development work in the attempt to open up new orebodies.

GRAHAM COUNTY.

A good gold strike has been made on the Buzzard Shadow claim of the New York-Arizona Co. The streak, which is 3 to 9 in. wide, is quite rich. Near this mine the Gold Belt Co. is working a promising claim. The shaft is 200 ft. deep; the vein is 12 ft. wide and is of good grade, it being also a gold ore.—The output for September of the Shannon Copper Co. was only 1,60,000 lb., it being cut down owing to numerous delays in getting the new furnace started.

PINAL COUNTY.

Recent development work at the Ray mine, in which S. W. Mudd, of Los Angeles, is interested, has added considerably to the ore reserves. The mill, which has been remodeled, will start within a month. It will have a capacity of about 250 tons per day.

CALIFORNIA.

BUTTE COUNTY.

The fire, which started Oct. 10 in the transformer, burned over \$100,000 worth of property belonging to the Nevada Dredging Co. at Oroville. A new dredging company, to be known as the Butte County Con. Dredging Co., has been formed to dredge Butte creek.

ELDORADO COUNTY.

J. D. Crawford has purchased the Stillwagon mine in Grizzly Flat from F. M. Davis.—The Larkin mine near Diamond Springs is to be reopened soon.—The machinery of the River Hill mine is being moved to the Sherman mine which is on the same vein. The Sherman mine is working two shifts. Work is being done on four levels; the shaft is not quite 500 ft. deep.

INYO COUNTY.

(Special Correspondence).—Inyo county is at present experiencing quite an activity in the various mining districts. The warm weather being over the prospectors are getting out into the hills again and many new finds are being reported.—J. V. McConnell has just returned from

Eureka Valley, where he has been making an examination of the Grand View group of claims owned by Geo. F. McPherson and others. In an interview Mr. McConnell stated that Mr. McPherson's property looked very well at surface. On one of the claims he has followed the vein down for 35 ft., at which point Mr. McConnell's sampling shows that the ore averaged \$48 per ton in gold and silver. It is the intention of Mr. McPherson and his associates to push the development work this fall and winter.—M. H. Crane reports a new find about 12 miles east of Big Pine in the White Mountains of between 3 and 4 ft. of lead carbonates which run very well in lead and silver.—J. W. Wright is pushing development work on his lead property east of this place and expects to make a shipment of high-grade lead-silver ore this week. Mr. Wright is doing no stopping, but is simply shipping the ore that is taken out in development work.

Big Pine, Oct. 10.

NEVADA COUNTY.

The Lecompton, Treadwell, Freedom, and Daybreak mines in Willow valley have been optioned to the Bankers'

Map of California.

Trust Co. The Lecompton and Treadwell belong to the Opp estate, while Norton claims, as the Freedom and Daybreak are known, had been bonded to the late Karl Howard. The mines will be consolidated and the new company called the Lecompton Consolidated. The company is also negotiating for other claims in the vicinity of those already bonded. The pumps at the Lecompton have been started and it is expected that the mine will be pumped out by Nov. 1. At first most of the work will be done from the Lecompton shaft. The Bankers' Trust Co., which is composed mainly of Kansas City men, is also working the Austin mine at Willow creek and the Republic mine near Graniteville. It is the intention to add 10 more stamps and work the Republic mine all winter.

The Ethel mine, owned by Maltman, Grissel, Goodwin, Christian, and others, has just been sold to an Eastern company. Much development work has been done at the Ethel during the last few years.

PLACER COUNTY.

George Wingfield of Goldfield has bought the Cook ranch near Auburn. Mr. Wingfield intends to prospect the property in order to try and refind the pay-streak in the old gravel channel which runs through the ranch; work will begin soon.

SHASTA COUNTY.

Judge Head of the Superior Court has decided the suit in regard to the title of the Golinsky group of claims in favor of B. Golinsky, the original locator. The decision hinged on the location of a missing section corner. This group of mines is under bond to the Guggenheims.

Last week the aerial tramway, which carries the ore from the Balaklala mine to the smelter at Coram, was started. This tramway is five miles long and there are 64 towers; the longest span is 1,200 ft. The large oil-tank at the Balaklala smelters has just been completed; its capacity is 500,000 gallons.—The Washington mine above French Gulch has been sold to J. H. Porter, C. E. Gilzean, and others. This old mine was famous in earlier days; the first stamp-mill in Shasta county was erected at this mine.

SIERRA COUNTY.

The mining property of Richard Phelan has been optioned to Col. Stephenson of Olinhouse, Nevada, who represents Eastern capitalists. This property consists of 27 lode claims and 3,000 acres of placer ground. The lode claims consist of four groups all near the famous Sierra Buttes quartz mine. The placer claims are mainly along the Lost Channel branch of the big Blue Lead and are mostly drift mines.

SISKIYOU COUNTY.

The Quartz Hill mine at Scott Bar has just completed a three-weeks' run; the clean-up yielded \$500. At present the mine is being worked under lease by C. F. Leavenworth.—The California Consolidated Co., whose mines are in Eddys gulch, has bought the Salmon river ditch and intends to put in a hydro-electric plant just above Sawyers Bar. The company will employ from 50 to 75 men in the future. The company is developing its mines preparatory to starting their 20-stamp mill. W. H. Young is manager.—Developments at the Homestake are quite promising. A raise is being driven to connect tunnel No. 3 with tunnel No. 2. The ore recently discovered in No. 4 level is quite good with patches of high-grade stuff.

TRINITY COUNTY.

The dam on East Fork, belonging to the Enterprise mine, is being repaired. It is expected that work at the mine will be resumed this winter.—The vein, recently discovered at the Morning Star mine in the East Fork district, contains a streak 8 to 12 in. wide of good ore.

TUOLUMNE COUNTY.

The Driesam mine is again working. The shaft at this property is 400 ft. deep but is badly caved; it has been retimbered to hard ground and will be opened again to the bottom. Twelve men are working at this mine; J. E. Conde is in charge at the mine.—The shaft at the Uncle Sam, which caved last winter, has been retimbered. Considerable development work is being done.—The Duffield and Sonora mines have been bonded by Parkinson and Backes. A new vein on these claims was discovered this summer and a drift 100 ft. long has been driven on it.—The rich strike, made in the Hunter Creek district some time ago by E. Calwell, is still looking well. The vein is two feet wide and carries some free gold.

COLORADO.

OURAY COUNTY.

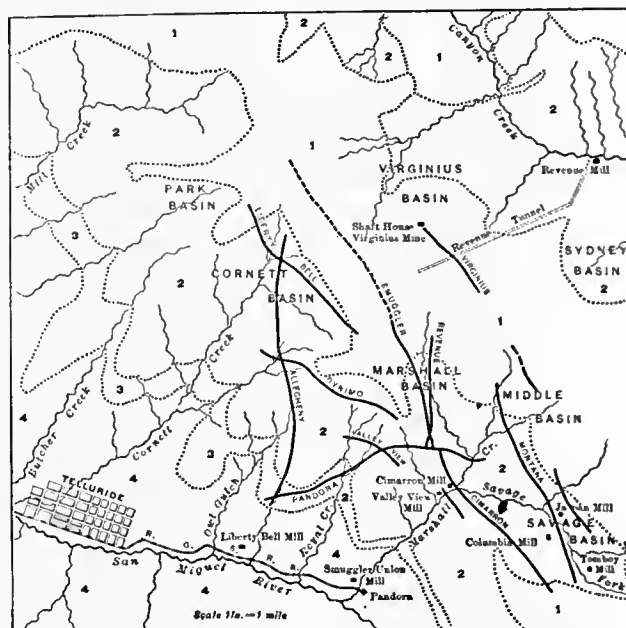

(Special Correspondence).—H. E. Procunier, manager of the Breen property in Poughkeepsie gulch, has recently overhauled the mill and new jigs have been installed. The mill now has a capacity of from 50 to 60 tons per day, and is run by Pelton wheels. Ingersoll and Hardsocg drills are used in development work. The main adit is in 1,900 ft. and is expected to cut the Consort vein within the next 225 ft. The Monarch adit, which is now 240 ft. long, has cut an ore-shoot 5 ft. wide; this adit will be extended in order to develop a second shoot which looks promising at surface.—The Revenue mill treats 45 tons per day, the ratio of concentration being six into one. This mill is being operated by lessees; each set—five in all—ship a car of concentrates each month.

Ouray, Oct. 11.

SAN JUAN COUNTY.

The Hamlet Co. recently opened up ore in No. 5 level, which is 300 ft. below all old workings. The ore carries gold, silver, zinc, lead, and copper. The mill consists of rolls, jigs, and Wilfley tables; the re-grinding being done by Huntington mills between the jigs and Wilfley tables. The capacity is 75 tons, but this will be increased shortly to 200 tons per day. W. E. Lloyd, the manager, estimates there is ore enough in the old workings to run three years besides the new ore-shoot recently opened, which gives 300 ft. more. Twelve machine-drills are in use; the Sullivan machines in the drifts and Waugh drills in the stopes. The property is on Galena Mtn. on the line of the Silverton & Northern Ry., which operates between Silverton and Animas Forks. The mill is operated by electric power furnished by the Animas Power Co., while the compressor uses steam.—Experimental work is being done at the Green Mountain Co. in Cunningham gulch with a view to making some changes in the mill.

The Old Hundred mill is undergoing some slight changes. The mechanical dryers, used in drying the concentrate, are being removed and the concentrate will be run into a drain-

Not Classified as to Geologic Age.	1 Rhyolites and Andesites.	Eocene	3 San Miguel Conglomerate
	2 San Juan Formation. Andesitic Breccia.	Jurassic and Cretaceous.	4 Shales and Sandstones.

Sketch Map of Telluride District, Colorado.

ing bin where a certain amount of water is drawn off and the concentrate is shipped wet instead of dry as heretofore. This will save sacking and the loss unavoidable when such material is handled dry. It will do away with a man to look after the dryers and a man to sack the concentrate; as against this the difference in the freight rate between shipping the concentrate wet or dry is slight. In shipping dry the concentrate contained about 1½% moisture, while wet it will contain about 7%. A canvas plant will be installed. Sixteen Callow settling tanks were recently installed, and according to J. M. Elmer, consulting engineer, the tanks are doing excellent work. There is one 8-ft. Callow tank to each vanner. There are 18 Card tables in use in the mill and one James table. The mill contains 40 stamps and has a capacity of 180 tons per day. A Robins belt-conveyor brings the ore from the bins at the tramway station to the bins in the mill. Pierce amalgamators are used after the plates and in this plant, as in a number of other plants throughout the San Juan; they are giving most satisfactory results. The Silverton & Northern Ry. has a spur running from Howardsville to the mill in Cunningham gulch. A large amount of development work is under way in the mine. One Denver Engineering Works electric hoist, good for 1,500 ft., is being installed and will be used in lowering ore to the mill-level, which will do away with the aerial tramway. It will also be used in bringing material from the

lower or mill-level to the station. The main adit, which has already been advanced several hundred feet, will connect with No. 7 vein and will give 2,700 ft. depth. The Eclipse drill-sharpener in use in the blacksmith shop is also doing good work. Howell Hinds, of Cleveland, is president.—J. H. Kramer has a lease on the old Ledge mill and is running the old concentrate dump, which could not be shipped at a profit in the early days; he is making a high-grade lead product.—It is understood that S. S. Graham, Jr., of the Elk Co. will install a compressor and drills to operate the property owned by his company in the Red Mountain district on the Cement creek side. This company has 32 claims and is estimated to have 15 veins to cut within 3,000 ft. The adit is 450 ft. long and have tapped one vein of pyrite. The property is situated on the line of the Gladstone & Northern railroad, joining Silverton to Gladstone.—The Hercules mill has been operating steadily on ore from the mine of that name, and regular shipments of concentrate are being made by Thomas Kane, the manager.

The Kitimac Co., in Minnie gulch, is erecting a 10,000 ft. Trenton Iron Co. aerial tramway and recently installed a compressor. Two machine-drills are in use and another is to be added. A cross-cut is being driven to cut the Isabella vein and incidentally a blind vein about 180 ft. from the Isabella has been encountered; it is said to show 19 ft. of milling ore, out of which about 20% can be sorted by hand, giving an average of \$30 per ton. The concentrate will average \$50. A mill will be built in the spring. James Kelly is superintendent; J. T. Joyce is manager.

T. Jay Hurley, manager for the Precious Metals Co., is operating the Silver Crow group, and last year equipped the property with a 10-drill Rand compressor and drove the adit 1,500 ft. in nine months. The last 1,000 ft. of work is on the vein and several good bunches of ore have been found, but no shipments have been made as yet. The property is situated in Mill gulch, near Chataanooga.

The new Silver Lake mill is operated in two units, one handling material from the Silver Lake mine and the other the ore from the Aspen mine owned and operated by the same company. This mill was designed with a view to giving plenty of light to the men employed as well as to get the best extraction. L. O. Bastain is superintendent of the mill; C. T. Van Winkle is assistant manager for the company.

The Detroit & Colorado M. Co. has just finished the new upper terminal of their tramway connecting with the Rio Grande railroad. Ore is being shipped at the rate of 15 cars per month. This went to the Ross smelter at Silverton, but since that plant has been closed down other arrangements will be made. The ore will probably go to the Salida smelter. L. L. Haines is manager.—The Mogul, near Gladstone, is installing a roaster for magnetic work. The mill has been closed for the past two months, awaiting the installation of magnetic separators. It is intended to start the mill shortly on 150 tons per day capacity and later to add more jigs and other machinery so as to increase the capacity to 300 tons per day. A large amount of development work has been done in the mine and the ore-bins are full, waiting the starting of the mill. R. W. Hollis is manager.

Silverton, Oct. 12.

SAN MIGUEL COUNTY.

(Special Correspondence).—The shaft-house and other buildings at the Mayflower mine were burned recently. It is understood that the buildings will be rebuilt as soon as possible. The company has almost completed the aerial tramway, which is to deliver the ore to the mill, that they are building east of the Liberty Belle mill.—The Black Bear Co., operating in Ingram basin three miles east of Telluride, have finished their upper tramway and expect within three or four weeks to have the lower one, which carries the concentrates to the Denver & Rio Grande railroad at Pandora, also completed. Both are Leschen trams. Ten stamps have been added to their mill, doubling its capacity. The mill contains eight Card concentrators; Pierce amalgamators are used below the plates. Many Pierce amalgamators are being used in the mills throughout the San Juan and good

reports are made of them in each instance. The Black Bear ore carries lead, copper, zinc, and gold. The company expects to ship each day two tons of crude ore besides the concentrates. O. Mantyla is president of the company.—At present the Smuggler-Union Co. is mining considerable ore on company count and have ceased to renew leases as they expire.—Some additions and changes are being made at the Tomboy mill.—The Smuggler Co. is erecting a testing plant, and, in case this treats the ore satisfactorily, a much larger plant will be installed.

Telluride, Oct. 10.

IDAHO.

SHOSHONE COUNTY.

(Special Correspondence).—The Snowstorm mine, three miles east of Mullan, is developed by four cross-cut levels from the surface of the mountain, which are numbered 1, 2, 3, and 4, beginning with the highest level. The lowest of these, or No. 4, is now being driven. Work has progressed about 1,700 ft. and when finished it will be 3,100 ft. long. No. 4 is 1,500 ft. vertically below No. 1. The tramway from the mill to the mine has two mine terminals, one at No. 2 level and the other at No. 3. The bulk of the present tonnage comes from stopes between levels No. 2 and 3. The ore is mostly a copper carbonate and very silicious, the copper being extracted by leaching. A considerable tonnage taken from No. 3 level, however, is a sulphide, which, on account of being high in silica, is suited to the use of smelters for converter lining and the shipments have thus far been for that purpose. The lowest, or No. 4, cross-cut, it is believed, will open heavy sulphide ore. The leaching plant, in charge of Mr. Rogers, is handling about 175 tons of ore every 24 hours. The company has two air-compressors—one operated by water power and the other by electricity. Improvements at the mines and at the mill are of the best, the bunk-houses, dining-rooms, and bath-rooms being strictly modern, affording accommodations equal to those of a first-class hotel.—Shipments of concentrates and crude ore by the Federal M. & S. Co. amount to about 10,000 tons per month. That company's Standard and Mammoth mills at Wallace handle about 27,000 tons of ore per month, its Morning mill at Mullan about the same tonnage, and its mill at Wardner handles from 12,000 to 13,000 tons per month. At the Morning mine the entire output is conveyed to the mill and shipping bins through a two-mile tunnel, which is on a level with the mill. There is a vertical distance of 1,000 ft. above this adit-level to the highest workings. A level has been run from each 200-ft. station.—Shipments of lead-silver ore and concentrate from the entire Coeur d'Alene district are estimated at 25,000 tons per month.—The Gold Hunter mine, situated near Mullan, has prospects of an increased production at one-third less in cost of mining and delivery at the mill. The lower cross-cut, which is on a level with the crusher-floor of the mill, was completed some time ago. It is 4,400 ft. long and intersects the orebody at a point 500 ft. below the old workings and 1,400 ft. below the apex of the lode. At the point intersected by the lower cross-cut, the lode measures 110-ft. from wall to wall. Within this lode are two orebodies—one next to the hanging wall and the other on the foot-wall. The two portions aggregate 50 ft. wide of solid ore. The narrow zone between the two highly mineralized bodies is also mineralized, but is low-grade. J. H. Gearon, superintendent of the property, states that the ore opened by this lower cross-cut will average 10% lead and 10 oz. silver per ton; and that heavy streaks of shipping ore will run 40% lead and 45 oz. silver. They have cut a station at this level and they are getting ready to rise on the orebody to the old workings. Within the next week or two all ore will be taken out through the lower cross-cut and the aerial tramway, which for several years has conveyed ore from the upper workings to the mill, will be discarded. As soon as preparations are completed the ore will be extracted through this lower level and production be increased to 300 tons per day, which will be milled. Facilities for sorting out the high-grade stuff are being put in and such ore will be shipped crude. Plans are in hand for installing a new

crusher in the mill and early next year the new cross-cut will be equipped for electric haulage.

Mullan, Oct. 11.

(Special Correspondence).—The principal feature of the mining industry in this district during the past week has been a cut of \$60,000 in the monthly dividend of the Bunker Hill & Sullivan mining company. For many months the company has maintained a regular dividend of \$180,000, but the dividend just declared for the month of September has been reduced to \$120,000. The decrease is directly due to the reduction of a cent and a quarter per pound in the price of lead. No reduction has been made either in the force of men engaged or in the output of the mine. The total dividends now declared by this company have reached \$9,786,000 of which \$1,740,000 has been declared this year. The decline in the price of lead has had a dispiriting influence in the Cœur d'Alene, but up to the present time the working forces at all the big mines remain the same as before. Some important strikes have been made during the week. The Vienna-International mine has cross-cut 16 ft. of the vein on the new level, recently started from the bottom of the winze, without reaching the foot-wall as yet; the ore exposed assays a little over 20% in lead and carries some silver and gold. Another big strike of antimony ore has been made in the Stanley mine and this, consisting of eight feet of clean ore, is the most important yet made in the property. At the bottom of the winze, which was sunk from the upper workings, from five to six feet of ore has already been exposed and the latest strike, made in a raise, has proved a stoping distance of 178 ft. The Stanley mine expects to make continuous shipments of antimony before the close of the present month. Work on the new compressor at Wardner for the Federal Mining & Smelting Co. is being rushed so as to have it installed before bad weather arrives. When this is installed the air-supply for the mines will be doubled; the new compressor will have 30-drill capacity. M. R. Rutherford, Ed. Donlan, J. L. Humble, G. F. Peterson, D. E. Peppard, W. H. Sedman, E. A. Winstanley, and C. E. Johnson, of Missoula, have made the first payment of \$12,000 on the three groups of claims near Murray, which they have had under option for the past nine months. The total price to be paid is \$105,000. The property consists of seven claims divided into the Keystone and Banner group, the Orofino group, and the Great Western group. Considerable work has been done under the direction of Mr. Rutherford and the showing is very promising. Up to this time all the work on these claims has been done by hand, but power from the plant at Thompson Falls will soon be supplied to the district. The Nabob, one of the most promising mines in the district and from which some lead ore has already been shipped, has closed down temporarily. It is understood that Harvey Ross, L. W. Gay, and George Stone, the principal owners, are negotiating the sale of it to the Panhandle smelter, in which F. Augustus Heinze is reported to have purchased a large interest. The ore, which has been shipped from the Nabob, carried 80% lead.—A cave occurred last week in the Hercules mine at Burke, in which two miners, Vincent Passadi and Larry Kiselico, were killed. The men were engaged in clearing away an old stope in the No. 2 level when the cave took place. For three days a force of from 50 to 75 men were engaged in digging for the bodies. A coroner's jury returned a verdict of unavoidable accident.

Wallace, Oct. 9.

NEVADA.

ESMERALDA COUNTY.

Two years ago 'Reub' Ryder took \$10,000 out of the Velvet claim; since then lessees have spent many thousands of dollars trying to find ore in the claim, but this pocket, from which the richest ore ever found at Goldfield came, appeared to be all the ore on the claim. But the Original Velvet lease finally discovered ore and last week shipped some high-grade ore. The ore was found on the 100-ft. level about 30 ft. from the shaft; the vein, which is two feet wide, runs east and west and dips to the south. A raise is being put up in the ore and cross-cutting has begun on the 250-ft. in the attempt to catch the ore there.—The output of

Goldfield for last week was 3,877½ tons of an estimated value of \$382,000. This is about 100 tons more than last week, but owing to the strike on the railroad the output was greatly curtailed. This especially affected the Mohawk, as it shipped only about half the usual tonnage. Last week the Mohawk Combination lease was closed down for several days. The Combination mill treated 540 tons in the six days that it ran. The shipments for the week were as follows: Jumbo dump, 385 tons; Mohawk Jumbo, 1,393 tons; Little Florence, 242 tons; Florence L. & M. Co., 97 tons; Hayes & Monnette dump, 30 tons; Mohawk mine, 500 tons; Red Top, 134 tons; Begole lease, 220 tons; Combination Fraction mine, 50 tons; Mohawk Combination, 280 tons; Original Velvet, 6½ tons. Total, 3,337½ tons.—The Begole is a sub-lease on the old Kalfus lease on Mohawk ground. This is its first shipment. The Mohawk Jumbo lease, which is producing the largest tonnage in the camp, is also doing the deepest mining. The ore comes from the 400 and 500-ft. levels. On the 500-ft. level of the Mohawk Jumbo, the deepest stoping in Goldfield, the ore is fully as good in grade as that above. Two other mines are down 500 ft., but comparatively little work has been done at those mines at that depth.—The two-compartment shaft on the Little Florence is 420 ft. deep and will be sunk to 575 ft. Four shifts are working in the shaft and record time is being made.—The strike on the Tonopah & Goldfield railroad has been settled and by now conditions have become normal.

LYON COUNTY.

The Union Blue mine, at Yerington, which is being worked under bond by F. D. Goodale of Denver, has just shipped a carload of high-grade copper ore. This mine is about 1½ miles north of the Ludwig shaft of the Nevada-Douglas.—The Wabuska Copper Co. is sinking a winze on the rich vein that was found two weeks ago. The winze is all in ore.—The Yerington Copper Co. has started to sink its shaft, which is 250 ft. deep, another 50 ft.—The Vladivostok group of claims has been bonded to Denver people. This group adjoins the Ludwig mine on the south.—There are no labor troubles at Yerington. The miners' union has decided not to ask for a raise in wages from \$3.50 to \$4.

NYE COUNTY.

At Manhattan the Mineral Hill shaft is 170 ft. deep; no water has been reached yet. It will be continued to water-level, where a station will be cut and cross-cutting begun. Stopping has commenced on the 65-ft. level of the Granny mine on Litigation hill. Considerable dry-washing is being done at Manhattan. The dry-washing machines on the Indian Camp and the Union No. 9 are making good clean-ups.—At Rhyolite the Shoshone mill is working quite satisfactorily. The three-compartment is being sunk deeper. At the Denver claim of the Tramp Consolidated a shaft from the 200-ft. level is being sunk. It is intended to sink this to a depth of 200 ft. in order to reach the original ore below the water-level. Rich shipping ore has been found in one of the leases on the Gibraltar property.

WHITE PINE COUNTY.

The ore line of the Nevada Northern, which will carry the ore from the mines at Copper Flat to the smelter at McGill is completed. Steam shovels are stripping the veins at Copper Flat. A four-compartment shaft 8 by 25 ft. in size has been started at the Veteran mine. This is to be the main shaft at the Veteran; raising has commenced from the levels below so as to hasten its completion. The large electric-driven hoist, built by the Denver Engineering Works for the Nevada Con., has been completed and is ready for shipment. This hoist will be installed at the Ruth shaft; it is the largest electric hoist ever built in the United States, being a 1,000-hp. hoist capable of raising 8 tons at a speed of 1,500 ft. per minute.

NEW MEXICO.

GRANT COUNTY.

(Special Correspondence).—The Forest Queen Copper Co. is developing 16 claims in the Silver City district. Several veins have been encountered, varying in width, and carrying sulphide ore that assays in zinc, copper, and silver. The

company is preparing to install steam hoists, a compressor, and other machinery. It has about 5,000 tons of ore on the dump. In one of the claims a vein of ore was struck which gave smelter returns of 7% copper.—The Exploration syndicate recently made a strike of copper ore in one of the shafts of their Copper Flat mine, in the Silver City district. The ore was struck at a depth of 200 ft.—The Eighty-five Mining Co. is doing a large amount of development work on its mine in the Virginia district. The ore runs about \$40 per ton in gold, silver, and copper. Two shifts are working.—The Enima copper mine, situated in the Fierro district, and operated by C. P. Cramer under lease, is a regular producer. A body of high-grade ore was recently uncovered.—A deposit of copper ore has been exposed in the Continental mine, owned by John Brockman and associates, and situated in the Fierro district.—Large ore deposits have been uncovered in the Philadelphia mine, situated in the Hanover district, the development work being done under the direction of B. F. Baker. The ore runs from 10 to 18% copper.

Silver City, Oct. 10.

OREGON.

BAKER COUNTY.

(Special Correspondence).—The mills at the United Elkhorn mines are again running, and a large tonnage of rich ore is being extracted from the mines; 40 men are employed. Edward I. Field is manager.—The tunnel at the Eagle Mtn. copper claims on Goose creek is being driven day and night.—The Sparta Co. is developing a promising group of 15 claims near Sparta. The ore carries gold and silver. Frank J. Habelt is directing operations.—The Oregon-Idaho Investment Co. is actively developing the Iron Mask group. The 120-ft. cross-cut is in ore said to run 6% copper, besides some gold and silver. James A. Howard is superintendent.—At the Poorman group a promising vein of copper ore is being developed. The cross-cut has opened a vein of ore 130 ft. wide.—Good ore has been struck in the Indiana mine. The vein is 7 ft. wide and is fairly rich in copper. Another 15-ft. lode of copper ore is also being developed. The ore carries some gold and silver, and the mine is being vigorously developed.—An Eastern company has purchased a number of claims near Paddy creek.—The copper belt east of this city is attracting attention, and several rich strikes have been made. Eastern people have secured some of the best claims and are actively developing them.—Grading is about to commence on a new railroad from Baker City to the copper belt. Local people subscribed \$100,000 toward the work.—Another road is being constructed from Union to tap the west end of the copper belt.

Baker City, Oct. 10.

WASHINGTON.

STEVENS COUNTY.

(Special Correspondence).—The Spokane Lead Co. is erecting a 50-ton concentrator in the Metaline district, which is situated on the Pend d'Oreille river, 60 miles north of Newport, Washington. G. A. King, formerly mill superintendent at the St. Eugene mine, Moyie, B. C., is in charge of the construction. The ore of the district, which occurs as deposits in the lime and at the contact of lime and slate, is a galena, not accompanied by silver. The milling grade runs about 10% lead and the plan is to concentrate three tons into one ton. It is stated that about 10% of the ore is of shipping grade, some of it running 80% lead. The ore outcrops, so that it is planned to mine some of it in open-cuts. An adit is being driven, however, to explore the deposit at a depth of 300 ft. A tramway, 1,800 ft. long, is being built. Three other properties are being developed near Metaline.

Spokane, Oct. 11.

WHATCOM COUNTY.

It is reported that the deal between A. A. Haug and the First Chance Mining Co. has been declared off, as the former did not live up to his agreement to start work at the mine by Aug. 1; so the construction of a smelter in the Mt. Baker mining district is in the air.—The Bonita and

Granite Creek mining companies have made good clean-ups during the year.—A 15-stamp mill is being erected at the North American mine, and the Minnesota is putting up a 10-stamp mill.

BRITISH COLUMBIA.

BOUNDARY DISTRICT.

Last week for the first time the ore from the Granby mines was hauled over the new Victoria Shaft spur of the Great Northern railroad. The ore output of the Granby Consolidated for the last week was the largest in the history of the company, being over 23,000 tons. In one day over 4,000 tons were shipped from the company's mines. In all, 41,000 tons were shipped from the camp during last week. Also another record.—Work has commenced on the steel flue-dust chamber at the Granby smelter. Three hundred tons of steel will be required in its construction.—The large blast-furnace of the Dominion Copper Co. reduced over 700 tons of ore per day during last week and is running quite satisfactorily.—The following interesting facts are taken from the Granby Con. Mining, Smelting & Power Co., Ltd. treasurer's report for year ending June 30, 1907: Produced 16,410,576 lb. copper, sold at average price \$0.222; 257,378 oz. silver, sold at \$0.679; 35,083 oz. gold, sold at \$20; total amount realized, \$4,521,549. Working expenses at mines and smelter, freight, refining, selling, and general expenses, \$2,442,456; outside ores purchased, \$154,156; total expenditure, \$2,596,611. Cost per ton ore, including all expenses, \$3.697; net cost per pound copper, after deducting gold and silver values, \$0.1014. Net profit for year ending June 30, 1907, \$1,924,937. Expended in new construction and equipment at smelter and mines, \$317,678; for additional mining properties, \$68,164. Mine development, 9,701 ft.; diamond-drill development, 7,279 ft. Granby ore smelted, 649,022 dry tons; outside ore smelted, 16,893 dry tons.

Development work will be continued all winter at the Maple Leaf, Franklin Camp. The Golden Eagle mine on the north fork of Kettle river is getting ready a shipment of ore to be sent to the Granby smelter. This will be the first ore to be sent out over the new railroad, which has been built up the north fork. Twelve men are at work at the Golden Eagle. The electric-driven air-compressor has been installed at the Crescent mine and work will be resumed immediately.

EAST KOOTENAY DISTRICT.

According to the annual report of the Sullivan Group Mining Co. for the year ending August 31, 1907, the operating profit was \$77,092. The bullion account, due the company, amounts to \$472,091, while the outstanding bonds amount to \$400,000. The net profit for the year after deducting the amount of all interest is \$45,442. During the year the company purchased the Big Dipper and the Euphemia Fraction mineral claims and at present holds an option on the Commonwealth. The smelter manager recommends that the capacity of the smelter be increased from 100 to 200 tons at a cost of \$65,000 to \$75,000, but owing to insufficient development below the 100-ft. level, the mine manager opposes this policy and recommends that the shaft be deepened and another level opened at 200 ft. It is stated that enough ore is in sight to keep the smelter going at its present capacity for 10 months or a year.

MEXICO.

JALISCO.

The Quien Sabe M. Co., organized to take over the mines near Ajijic, on the north shore of Lake Chapala, will cyanide its ore direct. The company has erected a 10-stamp mill, with the idea of concentrating. C. H. Maris is treasurer, and Walter Wheeler is manager.—Several railroad men have bought silver-lead-zinc properties near Platinar station, on the Manzanillo branch of the Mexican Central. James Martin will be in charge.

SONORA.

One thousand men have been laid off by the Greene-Cananea Co. at Cananea.

The property of the Sonora-Bonanza Co. at Magdalena, has been sold to the Superior-Bonanza Mining Co. of Calumet, Michigan.

Special Correspondence.

Salt Lake, Utah.

Views of Mr. Guggenheim.—Tintic Dividends.—New Smelting Company.—Strike at Park City.—Oil Discoveries.—Ore Shipments.

Daniel Guggenheim, president of the American Smelting & Refining Co., and several members of the executive committee of that corporation, visited Salt Lake this week. In an interview, Mr. Guggenheim made the significant declaration that his company expects to go right ahead with improvements in this State. "We have already invested a great deal of money in Utah and it is the intention of the American Smelting & Refining Co. to invest more. For instance, we expect to increase the usefulness of the copper smelter at Garfield. Its present capacity is between 2,000 and 3,000 tons of ore daily, and it is to be enlarged to give treatment to between 5,000 and 6,000 tons of ore per day." Mr. Guggenheim expressed the opinion that the present crisis in the metal markets will soon be passed, and, when the tightness of money eases up, there will be just as great a demand for copper as ever before. "I believe," said he, "that we ought to see a great change in the condition of things within the next sixty or ninety days. The trouble is we have had too much business in this country for the amount of money to do it with. There should be an improvement when the money required to move the crops is out of the way."

Referring to the Sherman anti-trust law, Mr. Guggenheim declared that it should be repealed. "The business of this country cannot live under this law," he said, "but we should have a law like that of Germany which permits the manufacturers to get together and agree along business lines, and, in a legitimate way, not to overflow the market with any commodity. Under existing conditions in this country, two or three miners might get into trouble for agreeing to close their mines to prevent just such conditions as confront the mining industry of the United States. The law might be successfully enforced against the copper producers for agreeing to a certain output. Why should not the producers get together and agree along lines of public policy to not flood the market with their wares?" Without entering a prediction as to the immediate future of lead, he nevertheless believed it to be the best interests of the producer to curtail production for the time being.

Six Tintic mining companies have posted dividends this month. The contributing mines and amounts being: Colorado, \$60,000; Beck Tunnel, \$20,000; Uncle Sam, \$15,000; May Day, \$12,000; Grand Central, \$12,500; Mammoth, \$20,000, the last returning to the dividend list after a year's absence. Owing to a curtailment of 50% in the output of the Colorado and Beck Tunnel mines, the total dividends were reduced. Construction work on the new plant of the Tintic Smelting Co., is being pushed rapidly and the management is counting on placing it in commission about January 1. It will treat 400 tons of lead ore daily, which is to come principally from the Colorado, Beck Tunnel, and Grand Central mines. Practically all the equipment and material for the 10-mile railroad, which is to connect the principal mines of Tintic with the smelter, has arrived. Track-laying began this week.—The ore shipments from the Tintic mining district last week amounted to 145 carloads, the contributing mines and amounts being: Ajax, 2; Bullock, 1; Beck Tunnel, 7; Bullion Beck, 5; Carisa, 3; Colorado, 9; Centennial Eureka, 54; Eagle & Blue Bell, 6; Eureka Hill, 2; Grand Central, 7; Gemini, 5; Lower Mammoth, 10; May Day, 7; Mammoth, 9;

Seranton, 3; Tintic Iron, 1; Uncle Sam, 4; Yankee Con., 4 carloads.

There is no prospect of a settlement of the strike of miners which resulted in the closing of the Daly West, Ontario, and Daly mines at Park City. Pending the depression in the metal market, no eagerness is being displayed to adjust matters. The miners' union, as an organization, demands recognition, and this the mine management refuses to do.—Active development has commenced again at the Uintah-Treasure Hill mine at Park City. The property is being worked through the Creole shaft. It is expected that ore shipments will be made before the end of the year.

The shutting down of so many mines in Montana and the curtailment that has been manifest in Utah camps has bettered the fuel shortage complained of recently. The smelting companies are now receiving coal for storage, while the domestic demand is being well supplied.—In accordance with the policy adopted at the Boston Consolidated mine at Bingham, which is operated under his direction, Samuel Newhouse has ordered a reduction on the output of the Cactus mine of the Newhouse corporation in Beaver county. About 300 men have been let out and the mill is to be run on one shift only, the ore to be treated coming from places where development is in progress.—The Ophir Hill Mining Co., of which W. A. Clark, of Montana, is the owner, has won an important apex suit; this will mean a heavier production from the property of that corporation at Ophir. Thomas F. Keely, of Chicago, and others, owners of the Montana mine, attempted to get extra-lateral rights with judgment for \$1,800,000, the value of the ore extracted.

The annual meeting of the Bingham New Haven Mining Co. resulted in the election of Louis E. Stoddard, president; T. W. Farnam, secretary and treasurer; who, with Fred F. Brewster and E. G. Stoddard, of New Haven, Conn., are directors. C. H. Doolittle, of Salt Lake, will continue as manager. This company owns the Bingham-New Haven mine, one of the principal producers of Bingham.—Great interest is being manifested in the oil discoveries made a few months ago in the Virgin district of southern Utah, and there is every reason to believe that the field is going to prove to be an important one. Salt Lake, Goldfield, and Los Angeles capital has become extensively interested there.

Joplin, Missouri.

A Better Zinc Market.—Figures of Production.—New Stock Exchange.—The Mining Congress.—Promising Finds of Ore.

The highest price reported paid for zinc ore last week was \$44 per ton and the assay base price ranged from \$38 to \$42 per ton of 60% zinc. Considerable more ore was sold above the \$40 mark than for several weeks, indicating a much stronger market. Lead ore sold at \$55 per ton at the best and that market was generally stronger, but there is little hope that this metal will advance very soon. Figuring the average output for the past eight months to the end of August at 25,732 tons per month and the September output at 17,840 tons, there is a decrease of 7,892 tons; add to this a decrease in the stock in the bins of 1,390 tons during the month of September, gives a total decrease of 9,282 tons. This is a conservative estimate of the total decrease due to the shut-down in September, but the producers responsible figure the restriction at 16,000 tons. The mistake they make is by taking the capacity of the mills included in the shut-down, instead of the actual production that each mill has made during the eight months of this year.

The shipment last week was the smallest of the year, amounting to: Zinc ore 8,369,600 lb., valued at \$159,321;

lead ore 1,370,230, valued at \$35,578; combined value, \$194,899. The shipment for the month of September was by far the smallest of the year, amounting to: Zinc ore 38,369,120 lb., valued at \$770,050; lead ore 4,468,870 lb., valued at \$122,217; combined value, \$892,267. The shipment for the 40 weeks of this year is: Zinc ore 459,082,270 lb., valued at \$10,471,257; lead ore 69,685,510 lb., valued at \$2,574,755; combined value, \$13,046,012. This shows an increase over the same period of last year of 35,155,550 lb. zinc ore and 8,777,400 lb. lead ore, and, in value, \$1,573,257.

At a meeting of the members of the proposed Joplin Stock Exchange held at the Joplin Commercial Club rooms recently, it was recommended that James F. Gallagher, of Boston, be made manager of the Exchange and his election is assured at the first directors' meeting to be held in the near future. It was decided to increase the membership from 100 to 200 and a committee was appointed to secure the extra 100 members. Clay Gregory was made provisional treasurer and was authorized to make a call for the first membership fee of \$25. Attorney F. W. Kelsey was selected to draw up the by-laws and

Luke land, west of Joplin on the Seventh St. road, is one of the new producers in the Joplin field. They made a turn-in last week of 36,000 lb. lead. They have a new modern 300-ton concentrating plant and the property is located in the new sheet ground district that promises to do much for Joplin and this end of the district.

Leadville, Colorado.

Monthly Output.—French Mountain Co.—The Iron Mask.—Resumption at the Greenback.—Shaft-sinking on the Roy Claims.—Electric Transmission.

The month of September closed with a total production for the district of 77,000 tons. Of this amount the local smelter received 60,000 tons.

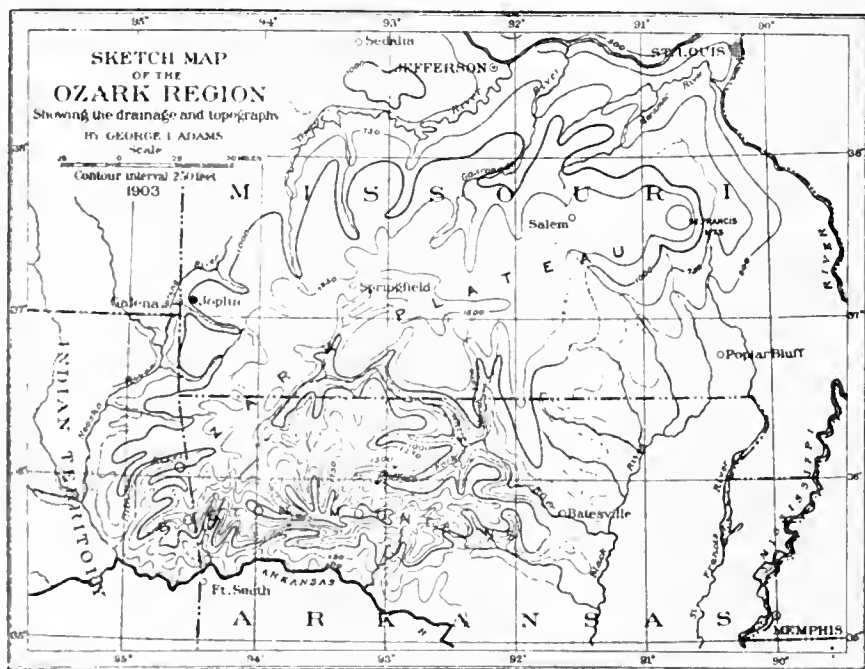

J. W. Bailey, of the French Mountain Co., states that a hydro-electric plant will be installed at his property on the mountain of the Holy Cross; it will have sufficient capacity to operate the new 120-ton cyanide plant and power for drills to push development work. The new cyanide mill went into service during the early part of the summer, but was unsuccessful on the unoxidized ore although

a good saving was reported on the surface ore. It is now intended to add a roasting plant to treat the refractory material. Some years ago an adit was driven over 600 ft. on the Grand Trunk vein, and at a point 660 ft. lower a second adit, which is now in 2,600 ft., has also cut the big vein. The vein is reported very strong at both levels, exposing a good shoot of \$30 milling ore.—The Old Iron Mask property will soon resume operations under the management of S. N. Hicks, with C. H. Harrington, of Denver, as superintendent. This property is situated in the Gilman district and has rivaled the Robinson, situated on the opposite side of Robinson mountain, in the production of lead and silver. A tonnage variously estimated from 500,000 to 1,000,000 tons is now developed and ready to stoep. The orebody is one of these complex

zinc and iron deposits for which the district is noted, carrying from 8 to 10 oz. silver, 18 to 30% zinc, 10% lead, and a small quantity of gold. The ores predominating in zinc will be treated at Leadville and the heavy iron ores will go to Pueblo.

The Greenback mine on the east slope of Carbonate hill is rapidly being put into shape for production and the shaft repairs will be complete in a very short time. A large station is being cut preparatory to the installation of a new station pump at the 900-ft. level. Large bodies of iron and zinc ores are known to be available, in fact, this property bears the reputation among local mining men of possessing the most important body of zinc ore of any property of equal area in the district. Some years ago a disagreement arose between the producers and the smelter management regarding treatment charges on the iron ores and as a result the mine was closed down indefinitely. The boiler plant, which consists of a battery of six 80-hp. boilers, is completed and the large first-motion hoist has been repaired ready for operation. A. M. Enslaw, of Salt Lake City, will manage the property and shipments will be commenced about November 1.

The showing made at the Mammoth, in Big Evans gulch, indicates that a large body of ore trends through

Map Showing Position of the Joplin District.

constitution.—The Arkansas mining district is making big preparations for the meeting of the American Mining Congress, which meets at Joplin on November 11. A whole carload of zinc specimens will be exhibited by the operators from that district and they will have an abundance of literature to advertise their mines.

Workmen have begun sinking a shaft on the George Koontz farm, a short distance northeast of Carthage, and are confident of finding ore, although no prospecting had been done with a drill, as is nearly always the case now before starting a shaft.—Kansas City parties have purchased the LeGrand Mining Co.'s lease of 35 lots on the Granby Mining & Smelting Co.'s land north of Chitwood. A mill is already built on the property and the new owners are remodeling this and making preparations for working the ground on which the mill stands. Some excellent strikes of both lead and zinc have been made on some of these lots.—The Good Day mine at Alba is a new producer that entered the list last week, turning in 108,000 lb. zinc ore. The mine is on the E. Aylor land north of Alba and gives promise of being a big producer. A modern 200-ton concentrating plant has just been completed.—The Cambria mine on the

the gulch toward the northeast. This belief has induced Thos. F. Walsh to make preparations to sink a shaft on the Roy group of claims, which side-lines the Mammoth tract. The manager, J. W. Benson, states that work on the new shaft will be commenced about Oct. 15 and will be sunk 600 ft. for the first lift. The Roy is situated to the northeast of the Mammoth and on the hillside, and the proposed shaft will be fully a mile from any producing property.—The discovery of a shoot of ore from six to twelve inches thick in a fissure vein on the Minneapolis claim has created considerable interest. The ore is silicious and of a shipping grade, but it is yet too early to estimate the importance of the discovery.—Attention was formerly called by your correspondent to the discovery of the old Robinson shoot in the shaft of the Interuational Mining Co., but later developments have convinced H. M. Shepherd, the manager, that the shoot

development while fuel is so expensive.—Frank Soder and Joseph Michlich, who have a lease on the Eclipse claim in Empire gulch, are shipping considerable ore. The ore runs better than \$30 per ton, principally silver. Transportation has been a serious handicap and will continue so until the Denver & Rio Grande railroad lays a switch into that part of the district.

Mexico.

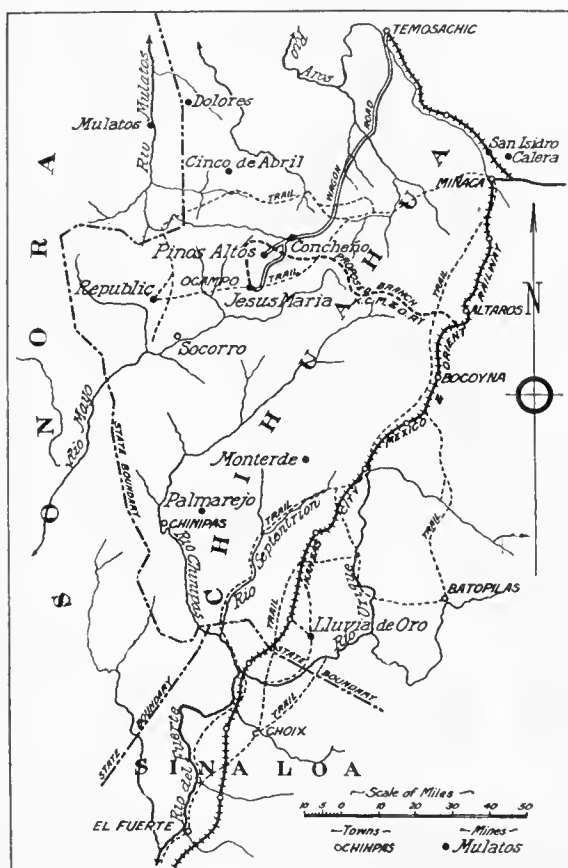

Rio de La Plata Co.—Litigation Over Ore.—Rapid Mill Construction.—Local Smelting of Stolen Ore.

The Rio de Plata Co. is successfully operating its 25 stamps and pans. The ore is rich, and the tailing is consequently high; this is being stored for re-treatment in a cyanide plant, a contract for which has been let. Considerable litigation is resulting from the discovery of more and better ore than the former owner supposed existed. The geological formation is said to be an "andesitic intrusion in Tertiary tufa." The country is much broken and the ore easily lost. Several good finds have been made lately on open ground in this neighborhood. The mill and residences are in the bottom of a narrow gorge over 2,000 ft. deep, which is supposed to have been a fissure originally. These gorges are the predominating feature of western Chihuahua, and are the cause of 15 to 20 horizontal miles being a day's journey.

The mill at the Guerra al Tirano mine started on Sept. 26, and has run continuously since. The ore is high-grade in gold, and the sorted ore from development work has paid for the mill and its transportation. On account of the desire of the manager, Frank Holmes, to have the mill running at the earliest possible moment, most of the iron work was sent from the States to the terminus of the railroad *by express*. From the railroad to the mine the mill was transported on mules for 12 days. The mill has been built in less than four months from the start. The ore is hard quartz, which is crushed through breakers to $1\frac{1}{2}$ in., then through rolls to $\frac{1}{4}$ in., and thence through batteries of 850-lb. stamps. On account of the hardness of the ore, this size feed is possible, and the capacity of the mill will be proportionately larger. Sand will be leached and the slime agitated, and then treated in a Butters filter.—The Palmarejo Mexican Co. is also under Mr. Holmes' management since the resignation of Mr. Pomeroy. Mr. Pomeroy had purchased a Butters slime-filter to supplement the weak point of their slime-treatment plant, and Mr. Holmes is pushing the construction of this addition. All slime has been impounded instead of being discharged into the river, and will be brought back to the filter for washing. The company is considering the expenditure of £60,000 for a power plant at the river and a large mill at the mine, in order to treat the low-grade ore that has been developed during the last hundred years, and which will not bear the cost of transportation and treatment at the Zapote 60-stamp mill.

Several *vasos* are now working continuously on ore, amalgam, concentrate, and cyanide precipitate, at Guazapares. One storekeeper purchased over \$3,000 of gold and silver bullion at this place in one month. These products are supposed to come from the various mines in the neighborhood, though none of the companies sell their product locally.—A number of groups of mines have been bonded in the vicinity of Chinipas, and several good prospects are being developed.

The Cia. Metalurgica y Refinadora del Pacifico, which is building a smelter at Fundiciou, Sonora, on the railroad, expects to blow in the early part of December, and will be in the market for the purchase of custom ores after November 1. W. D. Schellinger, superintendent

Map of Part of Mexico.

cut at the 1,120-ft. point was an entirely new body and totally unexpected. This new shoot is 12 ft. thick at the point cut. About 7 ft. consists of lead-zinc ore running 20% lead, 28 to 35% zinc, and 20 to 30 oz. silver. The lower 4 ft. is principally fine-grained galena with 30 oz. silver per ton. The sinking was resumed and at an additional depth of 80 ft. the Robinson shoot was cut, but no information is available at this date as to its extent and value.

An electric transmission line has been completed to the Ready Cash property and a branch line to the Long and Derry. Both properties are installing electric machinery to carry on their operation in the future. With the advent of cheap electric power, the old project of driving an adit into Prospect mountain has been revived. The promoters assert that an adit can be driven to cut every formation common to the district since the entire series of sedimentaries is tilted at a high angle in the section where the adit is proposed to be driven. Among the various contacts exposed, low-grade bodies of ore have been found, but of a grade too low to stand

for the San Javier Copper Co. of Chicago, Ill., is opening a new copper property in the vicinity of Batacosa, some 30 miles from Fundicion station. They are now down 60 ft. and report the prospect as very encouraging.

Johannesburg, Transvaal.

Tin Mining.—The Government to Operate a Mine.—Crime Among the Chinese.—Repatriation of Coolies.—August Output.—A Record.—Sorting of Waste.

One of the most unfortunate mining episodes since the war was what is known as the 'Sally' calamity. On property owned by the South African Lands (Sally's) tin was found, and on the strength of several reports, the shares were boomed sky high. When crushing operations commenced, it was found that the tin mine was a fiasco. Shares came down with a bump, and many people were ruined. It was thought that this episode would prove the quietus of tin in the Transvaal for some years to come. But tin is very much in evidence again. For some months past several parties have been working away on some tin prospects in an area north of Pretoria. No fortunes have been made, but the companies and individuals at work have made good profits by shipping their concentrate to Europe. When the Government announced that the area would be thrown open to public pegging on a certain day, there was a considerable preparation to get ready for the mad rush for claims. Some large firms had bodies of men ready to peg for them. At the last moment, to the surprise of every one, the Government withdrew the notice, and no claims were pegged by the public.

People now understand the Government's action in regard to the new tin fields, for it is now known that the Government intends to operate, in order to make work for the numerous unemployed white men now on the Rand. It is a bold scheme to run a Government mine. Unless it is managed better than some of the enterprises the Governments have run in this country, it will require solid tin to make it pay. The intentions of the Government are highly commendable. The local press applauds this practical demonstration on the part of the Government to relieve the distress now so prevalent on the Rand, but many fear that the enterprise will be mismanaged and that the burden of the experiment will fall on the hard-pressed tax-payer. It is proposed to send up a few experienced hands at first to do some prospecting, and others of the ex-strikers and other unemployed to follow later. If the new venture can even be made to pay expenses, then it is worth while, for employment will be found for some hundreds of white men who otherwise would have left the country. The full scheme of working the tin has not yet been worked out, but it is satisfactory to note that no Kaffirs will be employed, the white men being required to do all the work. To some of the men on the Rand who for years have acted as supervisors at very high rates of pay, it will be quite a shock to descend to manual toil. No doubt there will be a lot of grumbling at first.

During the past few weeks there has been a recrudescence of Chinese crime along the Rand. As the time of their departure draws nigh some of the coolies find themselves without any money with which to meet their gambling and other debts. To the baser sort of Chinese the simplest method of getting money is to go out and steal it. Several houses on the East Rand have been attacked, some of the inmates having been wounded seriously. In one case the owner of the house was murdered by the coolies. The whole of the gang was captured a few days after the crime, and are now being tried for murder.

The fact that they will not be allowed to exercise their option and sign on again for three years has come as a surprise to many of the coolies, who have reckoned that they had a long time in which to pay off their debts. Now that they know that all coolies are to leave at the end of the first three years, the Chinese are getting somewhat out of hand and are causing some anxiety. Extra precautions are being taken to keep the crime down to a minimum. So far all coolies who have left have been replaced by Kaffirs. No difficulty is expected this year in procuring sufficient Kaffirs for the mines.

The returns for August have proved a pleasant surprise to most people, for once again a record output is established for the Transvaal; and in fact for the world. The production for the month of December last, the record output, has been exceeded by 4,860 oz. The total output for August was 555,027 oz., valued at £2,357,602. Of this total the Rand contributed 534,598 oz., valued at £2,270,826. The total number of stamps at work in the Transvaal was 8,665, which is an increase of 85. The output for August was swelled considerably by the extra 11,750 oz. declared by the Robinson mine. The gold reserve at this mine has grown so enormous that it was decided to get some of the gold off the reserve account. For this reason the August declaration from the Robinson was declared at 35,714 oz., valued at £151,703. On the whole the mines do not seem to be sorting as much as they did previous to the strike. Some properties show that over 35% has been thrown out as waste rock, while on others there is no sorting at all. The fact that less sorting is being done, and that the wage bill for white labor is much less, tends to reduce working costs materially. One of the largest corporations on the Rand succeeded in showing the lowest working costs on record last month, namely an average of 19s. 10d. per ton milled. Feverish efforts are being made to cheapen the expense of production on the Rand. Had the Chinese remained, a fine record in costs for the Rand would have been established.

Toronto, Canada.

Suppression of Wild-Cats.—Action by the Government.—Ore Shipments From Cobalt.—News From the Mines.

Steps are at last being taken by the Attorney General of Ontario to suppress wild-catting in connection with the mining industry. Lately a number of worse than doubtful Larder Lake propositions have been put on the market and extensively advertised to catch small investors, shares being offered at as low as 10c., or even in one instance 6c. This week the firm of Law & Co., Toronto, received a warning as to the illegality of the advertisements of the shares of the Highland Mary gold mines of Larder Lake, which were being put on the market at 10c. per share. This proved effective in inducing them to withdraw their announcements. The action of the authorities is due to the outspoken and courageous course of *The Canadian Mining Journal* in pointing out the delusive character of the inducements held out by these advertisements, and the failure of the wild-cat promoters to comply with the stringent requirements of the law as to the specific information, which they are required to furnish, including the cost of property, preliminary and promotion expenses, and the extent of the interest of the directors in the enterprise. These requirements have been systematically ignored. While the daily press has from time to time vigorously denounced wild-catting—in the abstract—they have always been ready to accept the most obviously fraudulent advertisements with accompanying reading matter notices at so much per inch, endorsing their extravagant claims. The existing law is

ample for the protection of the public, but so far no attempt has been made to enforce it. A prosecution of some of the worst offenders may follow.

Shipments of Cobalt ore for the week ending October 5 amounted to 250 tons, from the following mines: Buffalo, 40 tons; Coniagas, 32; McKinley-Darragh, 86; Silver Queen, 32; Tretheway, 59.—An important strike was made last week on the Silver Leaf property while the surface men were prospecting for stringers 450 ft. from the main shaft. The vein is of calcite, smaltite, and native silver, and from 18 to 24 in. wide, and was uncovered for about 12 feet.

Butte, Montana.

No Further Decrease in Production.—Lessees Stop Work.—General Retrenchment.—The Barnes-King Fiasco.—The Wage Scale and the Price of Copper.—Pittsburgh & Montana Smelter.

There has been no further curtailment of the copper production by the Butte companies in several weeks, and no further reduction in the working forces at the mines

Montana.

and smelters, except that at the Clark Reduction Works there has been some interference with operations on account of the trouble with striking machinists, who have prevented other employees making repairs on broken machinery. The October copper production of the Butte district will fall below 9,000,000 lb. Of that amount the Great Falls and Washoe smelters produce about 7,000,000. These two smelters treat the ore of all the Amalgamated mines, the North Butte, Butte Coalition, and some custom ore. The only other producers of importance now are the Clark mines, and they add less than 1,800,000 lb. to the total output. The Pittsburgh & Montana and La France companies have produced nothing in October, and the latter has not produced since August. Nearly all lessees on copper ore have been shut off, and those employed by the East Butte Co. are about the only ones still at work. Lessees on the upper levels of the East Butte continue to ship ore to Utah for treatment, and the company treasury receives a round sum in monthly royalties even at the present reduced price of copper. The product of the two precipitating plants of the East Butte Co. is taken to the Washoe smelter, which no longer buys ore. Two carloads of concentrate from the East Butte concentrator were shipped to Ogden a few days ago. The East Butte recently stopped all dead

work, and is curtailing expenses, in common with all other companies in this district. Large reserves will enable the East Butte to ship ore as soon as the copper market justifies it. Considerable work has been done on the rich orebody recently opened on the 900-ft. level. The ore is 62 ft. wide, and contains 4 ft. assaying 12% copper, the remainder of the vein being good second-class.

The lessees in the Ophir mine of the Butte Central & Boston Co. are shipping a lot of high-grade silver ore to the Washoe smelter. Several large bodies have recently been opened on the 500 and 300-ft. levels of the Ophir, and the royalties paid by lessees more than pay the company's expenses.

The more the investigation of the Barnes-King Development Co. fiasco proceeds the more apparent and convincing becomes the fact that it was a deliberate swindle on the part of some one, though it has been difficult to fix the responsibility. A. J. Campbell, the chief promoter of the affair, is dead, and John C. Lalor, his associate, went to Europe about the time of the exposure, so that statements from two men who knew all the facts are not available. But it is known that a worked-out property, purchased for probably \$800,000, was unloaded on the company for \$2,000,000, and that the company received for the treasury from the promoters only \$400,000. What became of the difference has not yet been ascertained. Evidently the Butte contingent, the heavy subscribers, were confiding victims. They believed absolutely in the representations made by Campbell and Lalor and the engineers who experted the property for them. The reports were enough to mislead any one, and how they were made, or induced, is one of the things that has been puzzling the victims. A remarkable thing about the whole fraud is that after the new company took possession of the property, and the promoters had their managers in charge, the same glowing and promising reports continued to come from the property, and even when John Gillie, the new president, was engaged in examining the property and discovered that there were but 25,000 tons of ore in the mine, bogus interviews were sent out from Lewistown, where the mines are situated, quoting Mr. Gillie as saying the property was all that was represented, and that dividends would soon be paid, when the fact was that the possibilities of dividends were remote, and Mr. Gillie had the very poorest opinion of the property. The investigation now being conducted by Mr. Gillie and the new board of directors may disclose the guilty persons, and may also account for the missing funds. H. C. Brown & Co., bankers and brokers of New York, principal underwriters for the Barnes-King, say they were induced to interest themselves in the Barnes-King by Campbell and Lalor, who presented the reports of reputable experts, and also reported that they had made personal examinations of the property.

The Butte Miners Union says it intends to abide by the contracts entered into with the different mining companies relative to the wage scale, regardless of the action of the Western Federation, which repudiated the contracts. In reply to a notice from the companies that for the present they would not enforce the terms of the contracts but would continue to pay the \$4 day scale until the status of the metal market was more defined, the union sent this letter to the mining companies: "Your communication of Sept. 30 regarding the scale of wages under the present conditions and the price of copper was received and read at our regular meeting of Tuesday, Oct. 2, and we desire to notify you of the acceptance of it and to extend the thanks of the union for your attitude in this matter. We hope that the amicable relations existing between the companies you represent and the

Butte Miners Union will exist for an indefinite period of time. We realize that the agreement entered into between your companies and this union is binding on both parties, and fully appreciate your position in the matter in our behalf."

The Pittsburgh & Montana Copper Co. has decided to rebuild its smelter and put it in shape to treat its own ore again. The smelter was erected by Ralph Baggaley about five years ago as an experimental plant for his new process, but it proved unsuccessful, and the plant was shut down after the experiments had cost the company more than a million dollars. In order to make it good for anything the smelter will have to be reconstructed. The company has several large orebodies blocked out on the 800 and 1,200-ft. levels, much of the ore being first-class, and at the time the Washoe smelter stopped taking the company's ore it was shipping 8 to 10 cars per day. It is proposed to give the smelter a capacity of about 200 tons per day.

Denver, Colorado.

Smelter Rates.—Importation of Miners From Joplin.—The Stock Exchange at Colorado Springs.—Cyanide Plants at Cripple Creek.—Filter-Presses.

One of the most recent activities of the American Mining Congress is an inquiry into the relations existing between the ore producers and the smelting interests. An effort is to be made to ascertain the amount of truth there is in the often repeated charges that the smelters charge excessive rates for treatment and use their power to stifle all competition, their influence with the railroads as large shippers putting them in a commanding position. Where there is so much smoke there must be some fire, and doubtless when the investigation is finished it will be found that the charges against the smelters are partly true and partly untrue. That the charges imposed for smelting are high compared with smelting costs is undoubtedly true, but the producer and the smelter look at it in two different lights. The producer regards as a fair rate one that yields a reasonable profit over and above the cost of smelting. The smelters consider by what other means the producer might treat his ore, and at what cost, and then offer him a rate enough lower than that so that he will send his ore to them. In other words the principle is to "charge all the traffic will bear," which to Israelitish eyes is only sound business policy. Whether the Mining Congress can persuade them otherwise is more than doubtful. As to stifling competition, what influence the smelters have with the railroads and how they may wield it is hard for anyone not on the inside to know. But it is rarely necessary for the large centrally situated smelter to make any effort to stifle the small local plant, for the advantages are so enormously in favor of the former that the ambitious local smelter is generally overwhelmed after a brief existence, not to mention cheaper supplies, more favorable labor conditions, and the lowered costs incident to working on the larger scale; moreover, the control of a varied supply of ores to draw upon permits a more favorable smelting mixture, which immediately puts the plant dependent on a local supply (except in the few fortunate instances where the ore is self-fluxing) out of the running. Whatever the means to be taken to bring the American Smelting & Refining Co. into a more tractable mood, it is obviously not by the building of local smelters.

Last week 40 experienced miners from Joplin were brought to Silverton, and their arrival was the cause of much interest, as might naturally be expected in a camp that has been as short-handed as Silverton this year. The men are all experienced machine-men, an additional

boon, for the harassed superintendent has frequently been obliged lately to give charge of machines to men whose claims as drillers were founded on a couple of shifts tending chuck. The constantly increasing influx of the foreign element into the Colorado labor situation cannot but be a source of uneasiness to the observer, for the foreign element is undoubtedly the trouble-breeder. The 'bear-dancers' and other foreigners come crowding into the smelting centres and thence into the mining towns, gradually displacing the native workman and unsettling labor conditions in a way that is far from reassuring.

There has been a movement on foot to abolish the Colorado Springs Mining Stock Exchange, but it has been finally decided to retain it for the present. Cripple Creek has long ceased to be a 'boom' camp, and the particular form of gambling that masquerades as trading in mining stocks no longer flourishes in its vicinity. Nevada man-

Map of Southwestern Colorado.

ages to supply a little stimulus for it, but the days of prosperity of this particular exchange are past, and no bona fide producer mourns the passing.

Cyanide plants spring up so rapidly in the Cripple Creek district that it is a little difficult to keep track of them all. Most of the recent mills are rather small ones of 100 to 150 tons daily capacity, and are planned to treat oxidized ore. Some of them are already working with conspicuous success. The real problem at Cripple Creek, however, is the treatment of the low-grade unoxidized ore, of which millions of tons are already on various dumps, and many millions more underground. This material is too low-grade to stand freight charges, so the mills must be built at the mines. On the other hand, the high labor cost and the price of coal make roasting at the mines prohibitive. The treatment of such ore by cyaniding now seems to be the only method of much promise. One feature that seems not yet to be fully appreciated is the necessity for fine grinding. It must be remembered that these ores, with their finely disseminated tellurides, present quite a different problem from pyritic ores, where the gold in thin leaves lies along the cleavage planes of the pyrite, where it is easily reached by the cyanide solution. There seems also to exist along with this a prejudice against the vacuum-slime filters, such as the Moore and Butters. Two companies are experimenting with quick-opening positive-pressure filters, the Kelly and Chamberlain presses being the ones chosen for this purpose. The experiments seem to have produced a favorable impression in both cases, but are not far enough advanced for definite conclusions.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

IN treating silver-bearing sulphides by the cyanide process, fine grinding is imperative in order to get a good extraction. Besides, the rapidity of solution increases in proportion to the fineness of grinding. This fine grinding is expensive, but if the grinding is not fine, the cyanide consumption is high. The cyanide man must find a happy medium between these two evils and thus obtain the best results consistent with low cost.

ALLUVIAL MINING contributes greatly to the gold output of Victoria, in Australia. In 1906 there were 125 dredges working, 5 idle, and 18 building. Thirty-six bucket-dredges raised 8,243,010 cu. yd. gravel yielding 1.8 grains per cubic yard. The average weekly output for such a dredge (about 900 cu. yd. daily capacity) is approximately 22.7 oz. at a cost of about \$280. The average yield of the ground worked by 82 pump hydraulic mines was 2.85 gr. per cu. yd., while the highest return from any plant was 3.4 gr. per cu. yd. At 12 hydraulic sluicing plants the average was 4.12 gr. per cu. yd. The total area worked by hydraulic methods was 586 acres of river-bed and valley land and 60 acres of pastoral land.

THE Adair process of cyaniding slime, which has been used with considerable success at the Crown Reef mine on the Rand, is a system of agitating slime in the presence of manganese oxide, thus hastening the solution of the gold. The agitator consists of a central hollow shaft fitted with radial arms on which are stirring blades inclined on alternate arms in and out, respectively. The ends of these arms are attached to a hoop of angle-iron forming a wheel; around this passes an endless rope by means of which the agitator is turned. The cyanide solution is fed down the hollow shaft and out through the radial arms into the agitator-vat. The top solution is siphoned off into the precipitating boxes.

THE calcined precipitate from the zinc-boxes, in which a gold-bearing sulphide ore is being treated, is very apt to contain a good percentage of ferric oxide. The following flux has been found to give good results when smelting such a precipitate: Precipitate, six parts by weight; borax, six parts; sand, one-half to one part; fluorspar, one-half part; litharge, one-half part; carbon, as required. In this flux a large amount of litharge is used to replace the customary sodium carbonate. The litharge and fluorspar give a more fluid slag; this fact and the larger amount of litharge reduced, by facilitating the collecting of the gold, yield a cleaner slag. If there is not sufficient iron in the precipitate to bring down enough lead to impoverish the slag, carbon or iron must be added.

THE method of stull-timbered ore-filled stopes, similar to that used at the Camp Bird and other American mines, was introduced at the Great Fingall and other Australian mines when Bewick, Moreing & Co. assumed charge of them. At first this method was not liked by the Australian miners, probably owing to the fact that they doubted the safety of it. But owing to the successful use of this method at the Great Fingall, it is now in better favor. Where stull-timber costs about \$1 per foot as it does at Perth, it is merely a question of time when such a scheme becomes imperative. Ore-filled stopes are im-

practicable where the dip is low, for the ore must run easily into the chutes when drawing commences. At the Fingall, where the dip averages 55°, this method works admirably. In Australia it is called the 'shrinkage' method.

IN ORDER that rust may be formed, iron, oxygen, and water must be in contact with each other. Iron will not rust in dry air nor will it rust in water unless oxygen is present. There are three theories which are advanced to explain rusting. According to the oldest and most commonly accepted, the carbonic-acid theory, it is assumed that the presence of carbonic or some other acid is necessary in addition to oxygen in order that rust may form. The second theory presupposes the formation of hydrogen peroxide in rusting; consequently the prevention of the formation of hydrogen peroxide would prevent the formation of rust. The latest theory is the electrolysis theory. According to this theory the rusting is due to electrolytic action between different portions of the same piece of iron or steel. This happens because of slight variations in composition of different portions of iron or steel articles. According to this theory the presence of oxygen in the water is necessary in order to oxidize the hydrogen released at the positive pole of the couple and so prevent polarization. Experiments by W. H. Walker, of the Massachusetts Institute of Technology, appear to confirm this theory.

A QUARTZ mill was built in California and water taken for use in connection with such mill from a spring on vacant public land by means of a combination open flume and pipe-line. The mill has been closed for three or four years, but the owner has kept the flume and pipe-line in repair and has continuously used the water for domestic purposes. What would be the relative rights of the mill-owner and those of one who should locate the land on which the spring is situated?

Assuming that the spring in question flows, giving rise to a watercourse, or which would give rise to a watercourse were it not for the diversion of the waters thereof by means of the flume and pipe-line, and that a proper appropriation of the water has been made, the right of the mill-owner to divert the water under the circumstances above detailed would take precedence over the rights of the subsequent purchaser of the land from the Government.

The right of an appropriator of water may be lost by abandonment or by forfeiture; by abandonment, where an intention to surrender such right is accompanied by overt acts clearly manifesting such intention; by forfeiture, where there is a failure to put the water to a beneficial use, a non-user extending over a period of five years. In the instance noted above, there was evidently no abandonment. The act of the mill-owner in keeping the flume and pipe-line in repair evidenced the intention to keep the right alive, while the mere closing of the mill and the consequent non-user of the water for that purpose in the absence of something showing an intention to abandon the mill would not be sufficient to constitute an abandonment of the water right.

It is quite clear also that the right has not been forfeited, since the non-user for milling purposes has not continued for five years. At the end of such period, however, the owner of the mill would lose his water right based on his appropriation for mill purposes. Yet the forfeiture would not extend to his entire right to take water. Having put a part of all of the water so diverted to a beneficial use for household purposes, he would still have the right to the use of such amount of water as he had used for household purposes.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Professional Customs.

[In our issue of October 5 there appeared a series of questions put by a young mining engineer in quest of advice from the experienced members of the profession. We have received several replies, which are published herewith. Others will appear next week. For convenience of our readers, we reproduce the questions before giving the answers.—Editor.]

The Editor:

Sir—It often happens that young engineers are called upon to make an examination of mining properties before they have had any experience in work of this kind. Of course, there must be a first time for every engineer. Assuming that he is competent to make the examination and deliver the report, there are a good many minor questions regarding the etiquette of the transaction, the answers to which are not in the books; the only standard the young man has by which to gauge his procedure, is what the seasoned engineers can tell him, and the scattered and scanty information on this subject that is in print. Therefore, in behalf of the younger generation, I would like to ask the following questions, all of which are simple, many of which may seem unimportant, but most of which are of interest to the man who has had but little experience in examination work. If we could get answers to some of the questions from several men, we might deduce a series of useful rules. The objection will probably be raised that the questions are too ambiguous to be answered intelligently, as each individual case introduces diversified conditions. But it is impossible to arrange a more detailed set of questions in a compact form, so they must be treated in a general way. Assuming that the examination will consume from one to three months, and entails the necessity of a rather long journey on land and water, the man for instance starting from Colorado, bound for the tropics, and that the amount involved is about \$100,000, then;

1. Is it better to charge a fee, or undertake the work on a salary basis?

2. Is it advisable to have a written contract with your employers, properly drawn up and signed, or is the letter or telegram engaging you for the job sufficient?

3. Can a lump sum be demanded in advance to cover all the expenses of the trip?

4. Can the company properly be charged with all of the equipment necessary for the work, outside of the personal necessities of the engineer?

5. About traveling expenses. (a) Are tips to servants, laundry bills, tobacco, ammunition, medicines, etc., legitimate expense items? (b) Is the engineer entitled to the best first-class passage on train and on shipboard, and to the best accommodations at hotels? (c) If the young man be of an economical turn of mind, is it right for him to travel second-class, or even steerage, and charge the company first-class, he pocketing the difference? (d) How minutely must the details of the expense account be kept? Are frequent charges of 'incidentals,' to cover small expenses, permissible? (e) Is it best to take vouchers for large expenditures? If so, over what amounts? (f) Can expenses incurred in entertaining men while getting pertinent information from them, be entered on the account? (g) If the expedition consumes say three months, should the statement of expenses and cash bal-

ance be rendered weekly, monthly, or at the end of the engagement?

6. If you are sure of your fee, is it a good plan to send periodical reports on the progress of your investigation, giving results, such as assays, as they are obtained in the course of the work, or is it better to withhold all this information until your final report? Is the company justified in demanding frequent periodical reports of this kind?

7. If your examination indicates to you that the shares should be worth more than they are selling for on the open market, is it fair to buy these shares, before your report is turned in? Is it all right to do so afterward? In other words, is it permissible to use information gained at company expense, for private gain, during or subsequent to your term of employment?

8. Is it legitimate to take advantage of your presence in a district, to examine, and perhaps option mining properties for yourself, provided your employers are not in the field to purchase new ground, and no time is lost that properly belongs to the company?

9. Should there be any objection to publishing, in technical periodicals, a description of the district visited, giving general information of the conditions obtaining there, the topographical and geological features, and conclusions concerning the possibilities of successful mining, provided, of course, your employers will suffer no direct injury thereby?

10. Is it always expected of the engineer to say 'yes' or 'no' to the property? Even though the property is comparatively undeveloped, or badly opened, and the facts obtainable are insufficient for an intelligent opinion, must the engineer always reach a definite conclusion? If the mine is an old one, badly caved, is the engineer justified in spending company money to clear out old drifts, unwater shafts, and open caved ground, and may this work be properly charged in his expense account, without definite authority for such work from his employers?

T. S.

San Francisco, September 18.

The Editor:

Sir—A discussion of the relations which should exist between a mining engineer and his client in respect of mine examinations will be beneficial if it tend toward the establishment of just standards. The crystallization of custom in this regard will undoubtedly promote the general recognition of the profession as a necessary safeguard of prudent mine speculation, until the difference between a mining engineer and the so-called 'mining expert' shall appeal to the layman with the same conclusiveness as that with which he has learned to distinguish between an architect and a builder.

I would accordingly offer the following suggestions in answer to your queries:

1. The payment of a salary presupposes an engagement of indefinite length. Custom is making for a per diem rate in the case of occasional work, such as a mine examination. This invariably includes time spent in travel and in the preparation of report.

2. A telegram or letter of engagement is as legally binding as a contract, if it refers specifically by date to a letter or telegram, of which press-copy has been retained, in which terms were proposed. A telegraphic proposal of terms should, however, be repeated back to the sender to make the transaction safe.

3. An honest client will tender a sum in advance sufficient to cover the estimated total expense of the examination. If he does not, the engineer had better remain at home.

4. An engineer is supposed to have the necessary instruments of precision for surveying and measuring the property and orebodies, but insurance against their damage through accidents in travel should be involved in the client's obligations. Other equipments should be purchased and charged in the expense account.

5. As to traveling expenses: (a) Until the world is reformed, reasonable tips to servants are unavoidable, hence legitimate; laundry bills are excessive when traveling, and the unavoidable excess is a proper charge; tobacco is a luxury, and no self-respecting man would charge such an item to his client; ammunition for sport is also a luxury, but ammunition for personal protection, or to get meat in the wilderness, is a necessary expense; medicines are as much a necessity as bread, but the average engineer carries his medical kit, the occasional replenishment of which is a small item. If medical aid for other than chronic ailments be needed, it may properly be considered an accident of the journey, the cost of which naturally falls upon the client. (b) The engineer is entitled to first-class transportation, unless otherwise nominated in the bond. (c) Being therefore entitled to first-class comforts of travel, it is his duty to maintain the dignity, as authorized representative, of his principal, by traveling like a gentleman. To travel meanly and pocket the difference is dishonest for a two-fold reason. (d) Details of expense should be kept with the utmost possible minuteness. In the hurry of travel, however, it is often impossible to record every item, but it is a good rule never to allow 'incidentals' to exceed five per cent of the total costs. (e) Obtain vouchers wherever possible. No rule as to amount can be fixed, as, for example, it is impossible to obtain vouchers for railway tickets, hack-fares, etc. (f) Ingratiation of the engineer with others through entertainment often leads to results of the utmost value to a client, and such expenses are legitimate, but the charge should be accompanied by an explanation of the necessity for such entertainment. (g) It is usually wiser to defer rendering statement of expenses until the conclusion of the work.

6. Progress-reports upon a simple examination are prone to be misleading. Unwarranted conclusions are likely to be drawn from them. The engineer is usually rendering a more valuable service by waiting until he has collated his data, and is in position to submit a matured judgment. If development of mines is involved in the work, progress-reports may be necessary.

7. The client is entitled to all the benefit of the knowledge acquired by his engineer. The engineer has no right to speculate as a result of knowledge obtained at his client's expense, unless done with his explicit consent. In fact, a mining engineer with a proper regard for professional ethics will not speculate in mines or mining shares while he offers his services to the public as a consulting engineer.

8. This question is answered above.

9. It is unprofessional to publish a description of a district visited in a client's interest without submitting the manuscript for his approval in advance of publication in order that he may determine whether in part or in whole the article may affect him adversely. The above restriction does not apply to observations made while traveling outside of the district in which the examination was made.

10. The engineer must of course give definite advice to his client. That is what he is paid for. This does not necessarily involve a simple 'yes' or 'no,' but definite recommendations in the light of the facts about the mine and the conditions affecting its successful operation, taking also into consideration the terms under which the client may be able to come into possession of

the property, must be fully and clearly set forth. The questions of unwatering, clearing out old workings, and of doing new exploratory work, must rest with the judgment of the engineer. The terms of his engagement, the importance of the data obtainable without doing such extra work, and the proportion which the cost of the extra work necessary to reach a conclusion will bear to the costs already incurred, will be determining factors. This is not a matter of engineering propriety, nor of professional ethics, but of common sense.

COURTENAY DE KALB.

Los Angeles, October 7.

The Editor:

Sir—Referring to the interesting series of questions appearing in your issue of October 5, I beg to give the following replies:

1. It is best to charge a fee unless uncertainty exists as to the length of time necessary for the examination, in which case compensation had best be arranged upon a salary basis.

2. As a matter of business, a written contract is preferable; but if the employer is known to be reliable and responsible, as is generally the case, the letter or telegram should be deemed sufficient.

3. I would consider it eminently proper to ask for a lump sum to cover all expenses of the trip if it is not voluntarily offered.

4. It is permissible to charge the company with all of the equipment necessary for the work, outside of the personal necessities of the engineer, with exception of surveying and such other engineering instruments, which an engineer is supposed to own.

5. (a) Tips to servants, laundry bills, tobacco, ammunition, medicines, etc., are perfectly legitimate expenditures, but they should be carefully regulated and minimized.

(b) The engineer is entitled to the best first-class passage on train and on shipboard, and to the best accommodation at hotels.

(c) It is *not* right to travel second-class and charge the company first-class, pocketing the difference.

(d) Itemized accounts should be kept. Most employers do not expect itemized statements of expenditures, but they should be rendered if asked for.

(e) It is best to take vouchers for large expenditures. I would consider \$5 a low enough limit.

(f) By all means, expenses incurred in entertaining men while getting pertinent information from them, may be entered on the account, but such expenses should be fully explained in rendering the account.

(g) The statement of account should be reserved until end of trip unless employer should request statements at fixed intervals, in which case the engineer can have no reason to object.

6. Advance information is often misleading, and in some cases might even have to be revised, so it is best to withhold reports of results until the examination is completed, or at least so far along as to enable the engineer to formulate his conclusion. The employer is justified in demanding reports as to the amount of progress made, but not in asking for definite conclusions until all facts obtainable are in the possession of the engineer. There are, of course, exceptions, where such advance information would be invaluable to the employer, and in such cases the engineer will have to use his discretion as to the extent to which he gives such information.

7. It may be fair enough for the engineer, with the knowledge and consent of his employer, to speculate in the shares of the property examined, either before or after the report is rendered; but it is better for him to have

nothing to do with any such transaction, as it would tend to bias his judgment, and he would incur the risk of having his motives impugned.

8. There is no reason why opportunities to examine, and perhaps option, mining properties for yourself, should not be grasped, provided that the employer is apprised of the facts and offers no objection.

9. There is no objection to publishing, in technical periodicals, a description of the district visited, giving general information of the conditions obtaining there, the topographical and geological features, and conclusions concerning the possibilities of successful mining, provided, of course, your employers will suffer no direct injury thereby. On the contrary, it should be encouraged.

10. An engineer would be recreant to the trust imposed upon him if he should give a positive opinion regarding a property which he did not consider warranted by the facts. His report should be 'yes,' 'no,' or 'doubtful,' and the reasons for such opinion should be fully explained.

The expenditure of the employer's money to reopen old ground is fully justified where it is necessary to do such work in order to obtain definite information bearing upon the value of the property examined. If, however, it involves any considerable sum, the employer should, if practicable, be first consulted, before the work is undertaken.

R. CHESTER TURNER.

Berkeley, Cal., October 2.

The Editor:

Sir—There must always be a beginning, but the assumption that a young engineer is capable of undertaking an extended examination when he has had no experience in work of this kind is open to severe criticism. Many engagements as an assistant are necessary before the engineer is competent to undertake the entire responsibility of an important examination.

The questions submitted are, however, answered strictly in accordance with the assumptions stated in the letter of inquiry. Customs vary in different places, and it may be found advisable to settle some of the questions by agreement. The aim of the writer is to guide the young engineer within ethical lines.

1. To charge a fee whenever the extent and nature of the work can be arrived at with a reasonable degree of certainty is more dignified, but there is nothing inherently wrong in undertaking the work on a salary basis.

2. Specific understandings are desirable. Exchange of letters or telegrams in which essential matters are made clear is sufficient where the client is responsible. If the responsibility of the client is uncertain, decline the examination unless sufficient funds are advanced to cover expenses, and the amount of the fee is deposited in a bank to be paid on the presentation of the report.

3. Unless remittances are certain to be received when required, a sufficient amount should be advanced in the first instance to meet all expenses as they arise.

4. Certainly the client can be charged with all equipment necessary for the work outside of personal articles and luxuries; but it must be remembered that all unused equipment at the conclusion of the engagement is the property of the client.

5. The engineer should travel in the manner to which he is accustomed, but extravagance is not permissible in any case. To travel second class and charge first class rates is simply stealing the difference. While the expense account submitted need not go minutely into details, it is desirable to keep exact accounts of all expenditures; frequent charges of incidentals is not advisable. Vouchers should be taken when possible for all expenses. If it is found that the information obtained

warranted the outlay, the expense incurred in entertainment should be charged. Accounts should be furnished monthly if clients should so desire, otherwise at the end of the engagement.

6. If clients desire, there is no objection to submitting statements of fact as work progresses; this would be particularly desirable and necessary if the work was carried on under the instructions of a consulting engineer.

7. It is best that a young mining engineer own no mining shares, certainly not in any company with which he may be professionally connected.

8. In the absence of agreement to the contrary all options or information obtained belongs to the client.

9. There is no objection to publishing articles providing the consent of the client (in whose service the information was obtained) is received. On the contrary, it is most desirable. Every professional man owes something to his profession, and this is one way to pay installments on that debt.

10. More or less money must always be spent in clearing out workings before actual examination begins. It should be kept clearly in mind, however, that such expenses come under the head of money spent for the privilege of examining, and it rarely pays to spend much that way. In most cases the owner should undertake such work, if advisable at all. Engineers should certainly give specific advice based on the obtainable facts.

H. D. S.

San Francisco, October 4.

The Editor:

Sir—I take pleasure in giving below my opinions with reference to the questions asked by your correspondent, T. S., which seem to me very pertinent. I believe it would be exceedingly desirable if a more definite code of professional ethics could be established among mining engineers.

1. A professional opinion should preferably be charged for by fee rather than by salary. The essential object of an examination is the expression of an opinion, the value of which depends mainly on the engineer's ability and reputation, rather than the rendering by him of specific services. A usual and proper arrangement is the payment of a definite fee, in addition to a *per diem* payment for time engaged in the examination, directly or indirectly.

2. This all depends on the client. As a general rule, I should be inclined to say that when you are dealing with people of whom you know so little, or of whom your knowledge is so dubious, as to make it necessary to have a written contract, it would be better to demand and receive your fee in advance.

3. Yes. If the journey is a long and expensive one it is advisable, as well as proper, that an amount sufficient to cover all the estimated expenses should be paid in advance.

4. Yes. But surely an engineer is supposed to be reasonably well equipped with the instruments necessary for the exercise of his profession, just as much as with the requisite knowledge and experience.

5. (a) Yes. (b) Yes. (c) It may be right from an ethical point of view, but is surely inexpedient. (d) Expenses need not be noted in great detail. For short trips, my own practice is merely to note the amount of money taken with me, and that with which I return, and charge the difference to expenses, after deducting any obvious private outlay I may have made *en route*. (e) Yes, but vouchers are desirable, not so much for purely personal expenses as for other expenditures incurred by the engineer, such as for work done or for

possible to state any definite limit which should regulate this matter. (f) Yes. (g) When the examination is completed.

6. Your client may reasonably demand periodical reports as to results obtained during the progress of an examination, but in his interest, as much as your own, great care should be exercised in sending only such facts as you consider to be conclusively established. Do not volunteer provisional information unless it has been specifically asked for. The fewer half-digested opinions you form or express, the better.

7. To the first question my reply would be, emphatically, no. To the second, yes. But whether it is ever really desirable to make use, for the purpose of speculation, of information gained professionally, is a very doubtful question, as to which no general rule can be stated. It may seem a "counsel of perfection," but I should like to see all engineers taboo speculation in securities of enterprises with which they are connected, and I would even extend this to include enterprises with which they have been connected, and are likely to be so again.

8. No; unless there has been a previous distinct understanding to that effect between yourself and your employers. In the absence of such understanding, should you acquire options in a district where you have been present in the interests of others, they should be given an opportunity to avail themselves of them.

9. No. But statements as to the individual property to which your visit was made should be published only with your clients' sanction. Experience will usually guide the engineer in deciding correctly what information should or should not be published.

10. This question can hardly be fully answered without writing a volume. I am afraid it is always expected of the engineer that he should say 'yes' or 'no' with reference to the property; and often without sufficient information as to the essential factors, such as price, terms, and other conditions, on which alone any such answer should be based. Obviously the engineer can reach no more definite conclusion than the facts available will warrant. It may be necessary for him to report frankly that there were insufficient data to justify him in expressing a final opinion as to the value of the property, in which case he should state whether, in his judgment, the conditions warrant the expenditure of such time and money as will supply the deficiency. If workings are inaccessible on account of water, caved ground, etc., he should certainly consider himself justified in incurring a reasonable expense in opening them, and his own common sense, together with the commercial interests involved in his examination, must guide him as to the amount of such expenditure; but if at all considerable, the engineer, if he is wise, will endeavor to get into communication by wire with his client before he undertakes it.

GEORGE E. COLLINS.

Denver, October 4.

Weathered Pyrite.

The Editor:

Sir—An interesting query is raised in the issue of September 14, regarding the formation of the oxides of iron from the weathering of pyrite in arid regions.

Under ordinary weathering conditions, pyrite and other iron minerals will alter to the brown hydrous oxide of iron, consequently this is the most universally distributed form of iron. The process of change is often quite complex and not explainable by a single chemical reaction. Pyrite in oxidizing passes through the vitriolic state and then to limonite, often by such gradual

stages that the structure of the pyrite remains unchanged and the very common pseudomorphs of limonite after pyrite result. By age, pressure, heat, or simple dessication limonite may become dehydrated and form deposits of the red oxide or of the black crystalline hematite and magnetite. Outcrops of limonite in arid regions may become dehydrated by simple dessication and the red oxide croppings are more likely to occur in such regions than elsewhere.

Crystallized or specular hematite and magnetite are commonly constituents of the igneous and metamorphic rocks and deposits of them are generally associated with crystalline rocks. They are not products of weathering but of metamorphism in general. Pseudomorphs of both after pyrite are known to occur, but they are rare, especially magnetite pseudomorphs. The association of crystalline limestone would account for the formation of the anhydrous oxides. Pyrite altering in the presence of limestone usually forms limonite, the solution of bicarbonate of lime carrying off the sulphuric acid and leaving the hydrous oxide of iron. Magnetite can be formed by the action of alkali sulphates on iron; consequently, in arid alkali regions the decomposition of pyrite or other iron sulphides in the presence of the alkalies may account for the croppings of magnetite. The passage of the three oxides, limonite, hematite, and magnetite, into each other by simple hydration and dehydration is abundantly seen in nature, but in the case of the iron sulphides, hydration forms sulphuric acid and introduces a factor which complicates the weathering action.

ARTHUR S. EAKLE.

Berkeley, October 8.

CALCINING PLASTER.—A general plan of calcining plaster is as follows: The gypsum rock is crushed first in a jaw crusher; second, in a pot crusher; and then it goes to a rotary kiln drier. This drier is erected in brickwork like a boiler, and is equipped with an automatic feeder. If soft coal or wood is used as fuel, care must be taken that the products of combustion do not come in contact with the materials being dried, on account of the danger of discoloration. Fuel of any kind—oil, gas, coke, wood, or coal—is suitable. This drying process eliminates 10% of moisture. Next, the crushed rock is sieved in a trommel, generally to 24 mesh. The material that does not pass the sieve is ground in buhr mills, and this product, with the screenings from the trommel, is ready for boiling. The boiling is done in a large kettle with wrought-steel sides and cast-iron or heavy steel convex bottom. Flues pass through the kettle near the bottom and distribute the heat, which is applied below the kettle, and passes around the lower part of the sides, through the flues, and then around the upper part of the sides, and out at the stack. Inside the kettle is a shaft, which propels stirrers below the flues and mixing paddles above. The kettles are heavy and rest on brickwork. The ground gypsum is fed from bins into the kettle, and is constantly stirred and boiled until the remainder of the free moisture is expelled. The temperature of this preliminary boiling should not exceed 265° F., for at a higher temperature the water of crystallization, or combined water, begins to separate, and then the separation must be completed or the calcination will be a failure. To remove the necessary three-fourths of the combined water the material is then heated steadily to a temperature of 395° F. Care must be taken not to allow the temperature of this second boiling to exceed 400°, or all the combined water will be expelled, and the plaster will lose its setting properties.

Rules for the Guidance of Employees Underground.

Written for the MINING AND SCIENTIFIC PRESS
By R. CHESTER TURNER.

Few mines publish rules for the guidance of their employees, but it certainly is a commendable practice, as it safeguards both employer and employee and relieves the mine-foreman and shift-boss of the necessity for constantly reminding their men of many things that they should know without being told. It serves to put the miner, particularly the green hand, upon his guard against many of the dangers incident to his work, and it aids materially in the general disciplining of the mine force. It also, in many cases, relieves the company from responsibility for accidents due to carelessness of employees; besides, the enforcement of the rules will often save company property from serious damage or injury, and add materially to the efficiency of the working force.

Two codes of rules are given below. The first is in force at the Standard mine at Bodie, Cal., and the second is the list adopted by the Tonopah Mine Operators Association, and in force at the principal mines of the Tonopah district. Neither list is either perfect or complete, and it is with the hope that others of your readers may come forward with suggestions for their improvement, either by a process of addition, elimination, or revision, or by a combination of the three, that they are offered for publication, the idea being to eventually evolve a composite code of rules that will have general application. At nearly all mines some rules would have to be revised and others added in order to meet local conditions, but such a general code as it is desired to finally obtain would serve as a guide in almost all cases. The lists are as follows:

REGULATIONS OF STANDARD CONSOLIDATED MINING COMPANY.

POWDER must be thawed only in the appliances provided for that purpose. Powder fuse and caps always must be kept in boxes.

Miners are forbidden to use a tool of iron of any kind to load or tamp holes.

All missed holes must be reported to foreman or shift boss when miners are going off shift.

Holes shall be fired only at end of shift and just before meal hour, unless directions to the contrary are given by the foreman or shift bosses.

THE HEATING of lunches by means of candle snuffs will only be permitted in places specially designated by the foreman or shift bosses.

Miners are specially cautioned against dropping lighted snuffs.

Positively no lights must be left burning upon departure of shift, or at any time when leaving working place.

WHEN WORK is discontinued at any working place, miners working there last are expected to report to the foreman or shift boss the leaving of tools or supplies at that point.

TIMBERS, tools, etc., must not be left in raises or manways.

Miners starting to ascend or descend manways, must give notice of their coming and wait for answer from those above or below, if there are any, before proceeding.

Throwing tools down manways or chutes is strictly forbidden.

ANY MINER discovering bad or dangerous places in this Company's mines, will at once notify the foreman or shift boss.

No miner will lose his position by declining to work in a dangerous place.

THE TUNNELS and workings of the mine are for the use of the Company and its employees only. Peo-

ple desiring to visit the same must apply at the office for a pass.

No employee shall take strangers underground without a pass.

Tunnel earmen and shift bosses are expected to report at once any violation of this rule.

LEAVE OF ABSENCE must be applied for the day before.

Where absence is unforeseen, as in case of sudden sickness, word must be sent to the foreman or shift boss before the shift is due.

BELL SIGNALS as posted must be strictly followed. The station tender only is authorized to handle the bell rope.

Miners must not ride on a loaded cage.

ALL EMPLOYEES ARE EXPECTED TO READ AND POST THEMSELVES UPON THESE RULES.

FAILURE TO COMPLY WITH THE ABOVE RULES WILL RESULT IN SUSPENSION FROM THE ROLL.

RULES AND REGULATIONS ADOPTED BY THE TONOPAH MINE OPERATORS ASSOCIATION.

IN FORCE IN THE MINES OF THE TONOPAH DISTRICT.

1. **MINERS** are expected to clean down all loose rock in the roof and walls of the working places to which they are assigned before proceeding with any other work in such places.

2. **THROWING TOOLS** down manways is strictly prohibited.

3. **FUSE, CAPS, AND POWDER** must not be left lying in the stopes and working places, but must be taken, when near, from the supply points designated for the purpose. In taking powder, where a portion of a stick is used, the balance of the stick must either be used with the next charge, or else returned to the box from which it was taken, and in no case must it be thrown on the floor or in the gob and left there.

TAMPING with steel or any metal tool is strictly prohibited. Wooden tamping rods must be used for this purpose.

4. **MISSED HOLES** must be reported to the foreman or shift boss upon coming off shift. Write down the situation of such missed holes upon the black-boards or paper provided for that purpose.

5. **EMPLOYEES** are expected to report at once to the foreman or shift boss any dangerous condition about the workings that may come under their observation.

6. **IN THE EVENT** of anything, such as timber, tools, etc., dropping into the shaft, the cage tender must make a thorough investigation to satisfy himself that the shaft is clear before any further hoisting is done, and he must report accordingly to the foreman or shift boss.

7. **BELL-LINE.** Where a cage tender is employed, the bell-line is to be handled by him only except where an authorized employee wishes to go from the surface to a level above that from which the cage tender is hoisting, and in that event, he must ring one bell to notify the engineer that the cage is released after landing at his destination. In all cases the published code of bell signals must be observed.

8. **GATES.** When the cage is not at the station, the shaft-gate must be kept closed, and in every case it shall be the duty of the person operating the bell-line to lower the shaft-bar before the cage leaves the station.

9. **LIGHTED SNUFFS** must not be left at the stations or near any timber, unless in some receptacle specially provided to hold same.

10. **ALL EMPLOYEES** are expected to read these rules and post themselves regarding same. Ignorance of the published rules will not be considered a valid excuse for any violation of the same.

The bell-signals and rules in force at Bodie are those of the California State Code, and they are practically the same at Tonopah.

The Desert Mill.

Written for the MINING AND SCIENTIFIC PRESS
By A. R. PARSONS.

The 100-stamp mill and power-plant of the Desert Power & Mill Co., operated by the Tonopah Mining Co. of Nevada for the purpose of milling the ore produced from its Tonopah mines, is situated at Millers, Nevada, a station on the Tonopah & Goldfield Railroad 13 miles west of Tonopah.

The entire installation, both mill and power-plant, was made by Chas. C. Moore & Co., of San Francisco, to whom a contract for the work was given. A little over one year was required to complete the mill. Mr. John H. Hopps of San Francisco acted as consulting engineer.

The power-plant contains four Babcock & Wilcox water-tube boilers of the vertical header type, provided with superheaters, set in batteries of two each. Each boiler contains 2,036 sq. ft. of heating surface. The boilers are arranged for firing with either coal or oil; the Moore oil-burning apparatus is used. Natural draft is obtained by means of a 66-in. steel stack 150 ft. high. A Green fuel-economizer utilizes the flue-gases. The minor boiler-room equipment consists of two Snow duplex boiler-feed pumps, Goubert feed-water heater, automatic relief-valves, stop and check-valves, damper-regulator, hot well, steam-traps, feed-water meter, thermometer, etc., all of which is ample and well arranged.

There are three 14 by 28 by 30 in. horizontal cross-compound side-crank McIntosh & Seymour gridiron-valve engines, each condensing, arranged for direct connection to 250 kw., 25 cycle, 2,200 volts, 150 r.p.m. alternators. There is also one 15 by 32 by 30 in. McIntosh & Seymour engine as above, directly connected to a 300-kw. alternator. All electrical equipment was furnished by the Westinghouse Electric & Manufacturing Co. The exciting current is supplied by 125-volt direct current exciters, belted from the band-wheel of the generators.

Condensation of steam from the engines takes place in Edwards condensers, equipped with power-driven air-pumps. The circulating water for condensing is pumped, by means of 8-in. double-suction Wheeler centrifugal pumps directly connected to 40-hp. motors, to a fan-driven steel water-cooling tower. Suitable switchboards with generator panels and distributing boards for mine and mill are conveniently placed in the engine-room. Step-up transformers raise the voltage from 2,200 to 22,000 for transmission over the 12-mile line to the hoists at the shafts in Tonopah. Step-down transformers lower the voltage at the mill from 2,200 to 440, all the mill-motors being 25 cycle, 440 volt Type C.

Water for the mill and power-plant is pumped by a two-stage vertical centrifugal pump from a well 60 ft. deep, situated 1,700 ft. north of the plant.

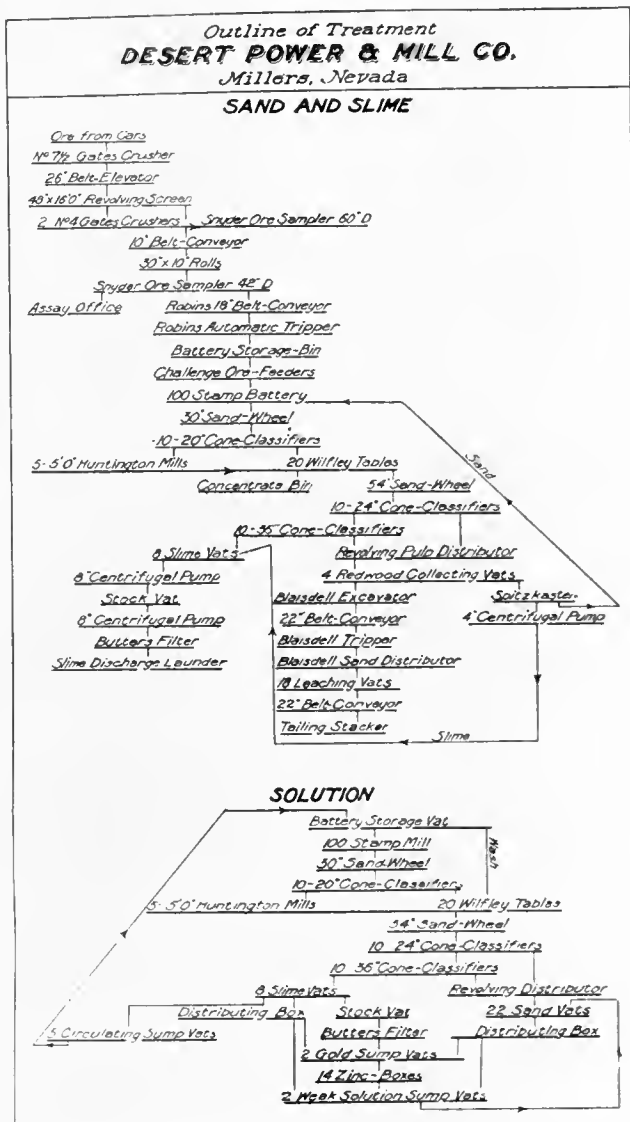

The main mill-building, 525 by 230 ft. in extreme dimensions, is erected on ground having only a 3% slope. The crude ore from the mines is taken up an incline trestle in steel hopper-bottom 50-ton railroad-cars in lots of seven cars to the crusher ore-bin.

The orebodies of Tonopah are largely replacements of andesite by quartz, forming parallel or branching veins and veinlets of quite solid quartz, separated by mineralized andesite, which frequently assays well. The ore as stoped, is therefore a mixture of quartz and 'porphyry.' Some of the early barren porphyry is sorted out before the ore is sent to the mill.

The primary ore of Tonopah consists of a gangue of quartz with some sericite and adularia, with a small percentage of the carbonates of lime, magnesia, iron, and manganese; the silver is present mostly as sulphide and

sulphantimonide; gold is never visible and occurs in some form not yet determined; small amounts of pyrite and chalcopryrite occur, with traces of lead, zinc, arsenic, selenium, and other metals.

All of the ore now being treated at the Desert mill is partially oxidized. This oxidation, however, is never complete and most of the silver is still present in the form of argentite, which is probably mixed with stephanite, but in the more oxidized phases cerargyrite (horn silver), frequently containing iodine and bromine, is common. The carbonates of the primary ore are represented by oxides of iron and manganese, and gypsum. In the process of oxidation, a large proportion of the

iron, manganese, antimony, arsenic, copper, lead, zinc, and selenium originally present, has been removed. In none of the ore, however, are the base metals present in sufficient quantity to be valuable.

A sample of rich ore from the Valley View vein analyzed by Hillebrand of the U. S. Geological Survey gave the following results:

Ag	62.54%	(38.10 as sulphides, 24.44 as chloride, sel- inide, and alloy.	Au	0.62%
			Fe, Mn	1.46%
			Cu, Pb, Mn	0.51%
			Se, Sb, As	0.96%

The ratio of silver to gold by weight in the ore treated at the mill is about 90 to 1.

The coarse-crushing and sampling department is in a separate building. The crushing plant has a capacity of 400 tons in 8 hours. Power for driving the machinery is supplied by a 125-hp. motor and the 18-in. Robins belt-conveyor for carrying ore from the crusher-house to battery storage-bin is driven by a 15-hp. motor.

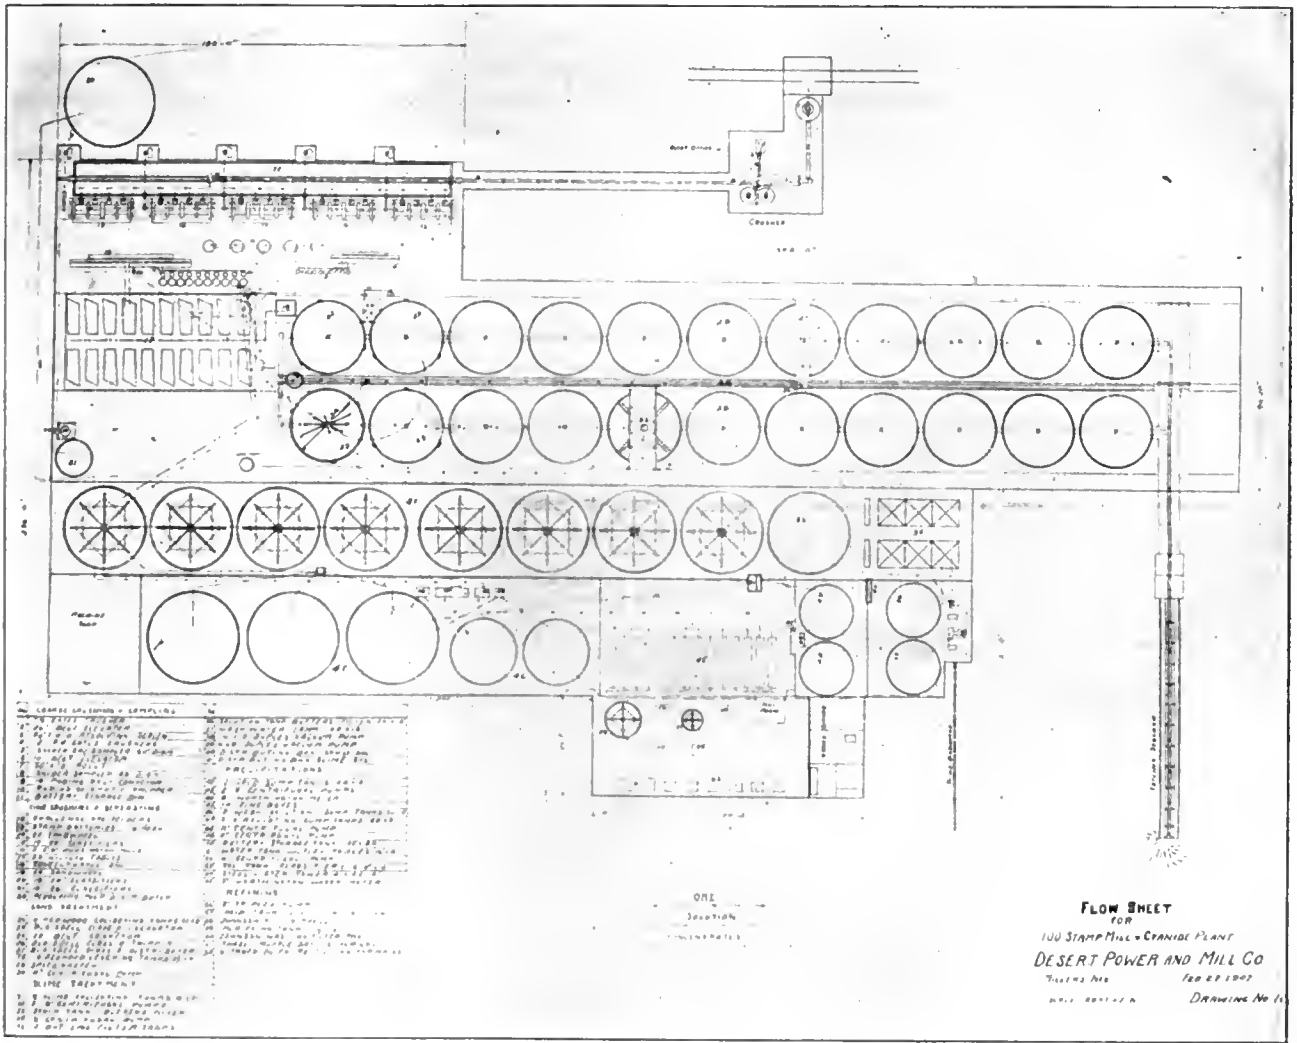

The mine-run from the bin is fed through a finger

gate to a 7½ Gates crusher, Style K. This reduces it to a maximum size of about two inches, in which condition it is elevated by means of a 26-in. steel bucket-elevator to a 48 in. by 16-ft. revolving manganese steel screen with 1½-in. holes. The oversize from the screen passes to two 4 D Gates crushers for further reduction. The product from the smaller crushers unites with the screened product and passes through a 60-in. Snyder sampler. The reject from the sampler falls directly upon the 18-in. conveyor. The cut out from the sampler is elevated by a 10-in. steel bucket-elevator to a set of 30 by 10-in. rolls for fine grinding. The product from the rolls is passed through a 42-in. Snyder sampler, the reject from which falls upon the conveyor and the 'cut out' is taken to the assay office for further sampling and pulping. The 18-in. conveyor with troughing idlers

12-mesh wire screen, the height of discharge being three inches.

Chrome steel shoes and dies have been in use and cast iron dies containing a percentage of steel are being tried with satisfactory results, a more even wear of both shoes and dies being obtained by the combination. Both shoes and dies are worn down to a thickness of less than two inches, compensation for loss of depth being made up by cast iron false dies of varying thickness. The chrome steel dies average 1,736 stamp-hours, crushing 315 tons of ore each. The shoes average 1,011 stamp-hours, crushing 285 tons each. The steel consumption of dies and shoes is respectively 6.70 and 7.60 oz. per ton of ore crushed.

The battery-crushing takes place in a solution carrying 0.15% potassium cyanide, supplied from a 188,000

takes the ore up a 22° incline and distributes it by an automatic tripper over the battery storage-bin, having a capacity of 1,500 tons.

Rack and pinion gates regulate the ore going to the 20 Challenge feeders, supplying the 100 stamps. The mortars of the stamp-batteries are the narrow pattern, single discharge, manufactured by the Union Iron Works. They are set on substantial concrete foundations down to hardpan, rubber sheeting ½ in. thick being placed between the mortars and the top of the concrete. End and side liners of malleable cast-steel are used in the mortars.

Each battery of 20 stamps is driven by a 50-hp. motor, the order of dropping stamps being 1-3-5-2-4. The weight of each stamp is made up as follows: Stem, 427 lb.; tappet, 140; boss, 320; and shoe 180 pounds.

The stamps drop 104 times per minute through a height of 6½ in. and have a duty of 4.31 tons crushing through a

gal. storage-vat that is filled by 8-in. Butters centrifugal pumps, taking their suction from sumps at the lower end of the mill. The pulp from the battery (7 of solution to 1 of ore) flows to an inside bucket-elevator wheel, 30 ft. diam., driven by a 7½-hp. motor. The wheel elevates the pulp to ten 20-in. double cone-classifiers with hydraulic upward current of cyanide solution. Sizing tests:

Screen Mesh.	Battery product.	Overflow from classifiers.	Spigot discharge.

" 100	10.82	15.90	6.67
Pass 100	31.77	50.30	11.65

The overflow from the classifiers passes directly to ten

No. 5 Wilfley concentrators. The bottom-discharge through $\frac{1}{2}$ -in. spigots, containing the coarse product for re-grinding, flows to five 5-ft. Huntington mills, equipped with 30-mesh screens. Three mills ordinarily re-grind the oversize product from 80 stamps. A 50-hp. motor drives the mills and a bucket-elevator for raising the product from the mills for distribution over the 10 concentrators.

The 20 Wilfley concentrators are securely anchored to a concrete floor with sufficient slope to allow drainage of any leaks or drips to the tailing-launders beneath the level of the floor, the launders also being made of concrete. The tables make 240 strokes ($\frac{3}{8}$ to $\frac{1}{2}$ in.) per minute, the length of stroke varying with the class of material passing over each table.

Classification and dewatering of the product to the Wilfley concentrators is obtained by a series of V-boxes receiving the pulp from the launders carrying the overflow from the 10 double-cone classifiers and re-ground product from the Huntington mills. It is intended to install additional concentrators to take the middling from the present equipment, as experiments have demonstrated that an additional saving of about 10% can be made in concentrating, at the same time removing sulphides difficult to treat in the cyanide department. At present, 90 tons of ore produce 1 ton of concentrate, averaging 4.5 oz. gold and 815 oz. silver per ton. These are partially dried to about 12% moisture by draining and vacuum applied to a small vat receiving each day's output. The concentrate is sacked each day in canvas bags and shipped to the smelter in carload lots. The recovery by concentration from March to August, this year, was 15.63% of the gold and 30.32% of the silver contents of the ore milled.

A 30-hp. motor operates the 20 Wilfley concentrators, one 4-in. Butters centrifugal pump used for pumping wheel-pits, a Johnston vanner (used in experiments), and a small bucket elevator.

The tailing from the concentrators is elevated by means of a 54-ft. wheel to two sets of ten double-cone classifiers with hydraulic upward current of weak solution. The overflow from the upper set of 24-in. classifiers goes to the lower set 36-in. diam. The overflow slime and solution from the lower set of classifiers flows to the slime plant through a series of spitzkasten for removing the very fine sand.

The sand and solution from $\frac{3}{8}$ -in. spigot-discharge of both sets of classifiers and spitzkasten flow through a wooden launder to a revolving wet distributor of the Butters & Mein type. This distributor is hung from a circular overhead trolley so that it can be swung to any one of four sand-collecting vats. These, as well as the 18 leaching-vats, are 33 ft. diam. by 8 ft. deep, provided with cocoa-matting and 10-oz. canvas filters laid on wooden strips, the filters being raised three inches above the bottom of the vat. The collecting-vats are provided with roller blind-overflow gates for a further separation of sand and slime. Some sand that overflows with the slime from these gates, is removed by a large pointed box receiving the entire overflow from collectors. The slime and solution from the pointed box are returned to the launder going to the slime-plant by means of a 4-in. Butters centrifugal pump.

For treating the sand, a collector is filled to a depth of five feet; this amount of packed sand, after transfer, fills a treatment vat. After a collector is filled, the distributor is swung to one of the other collectors, and the drain-valves opened for 24 hours; then a vacuum is applied to dry sufficiently to permit of excavating by means of a Blaisdell class A disc-excavator. This machine is mounted on a track and can be moved by electric motor

and trolley to any sand-vat. A wrought-iron conical plug 22-in. diam. seated on a rubber gasket in a cast-iron flange in the vat is removed by means of a chain-block attached to the excavator. This leaves a clear opening from the top of the sand to the 20-in. Robins troughing-belt conveyor running below each row of vats, through which the excavator discharges the sand. It requires from 2 to 3 hours to excavate 250 tons of sand, the time depending upon the moisture in the material. The excavated sand is conveyed to a cross-conveyor at the east end of the sand-vats. The cross-conveyor, running up an incline, discharges to a conveyor of the same type running between the two rows of vats and above them, over a Blaisdell class A tripper. From the tripper, the sand falls upon the cross-belt of a Blaisdell class Z sand-distributor, then on to a rapidly revolving disc with speed-regulating device by means of which the sand is distributed about the vat in a fine shower, and at the same time, thoroughly aerated.

While transferring the sand from collectors to leaching-vats, lead acetate, previously dissolved in water ($\frac{1}{2}$ lb. per ton) is allowed to drip upon the sand on the conveyor-belt and slacked lime (4 lb. per ton) is thrown into the collector in which the excavator is working, thus thoroughly mixing the lime with the sand. After transferring, a little shoveling is done to level the sand. The first leaching solution, amounting to 30 tons, is brought up to 0.25% strength by the addition of a sufficient amount of potassium cyanide solution of known strength to the vat undergoing treatment. This pumping of strong solution is allowed to drain slowly through the partially opened drain-valves and is followed by repeated pumpings of weak solution from 0.15 to 0.20%, after which the charge is drained for transfer. This first treatment occupies five days, including time of transfer.

The second treatment averages five days and consists of repeated pumpings of strong and weak solution, that are drained and the sand transferred to another vat for the final treatment, which consists of as many pumpings of wash solution as there is time to apply, followed by two or three pumpings of water to displace all the solution. Then the vat is finally drained by vacuum for discharging from the plant. All pumpings of solution are allowed to disappear below the surface of the sand before the succeeding one is applied. Sand undergoes treatment for 12 to 15 days. Moisture in sand discharged averages 15%. Sand residues at present average 0.03 oz. gold and 3.10 oz. silver per ton.

-sizing test on sand residues.

The treated sand is discharged by the excavator upon the sand-conveying system, so arranged as to run in the direction opposite to that when transferring. The sand as it is discharged falls upon a cross-conveyor running up an incline of 25°. As the tailing-pile builds up to the stacker, an extension of 18 ft. is added at the end. Arrangements are being made for a cross-conveyor in connection with the stacker.

All leachings from the sand-vats, as well as the plant solutions, are sampled, assayed, and titrated for cyanide and alkalinity daily. Attenuated leaching solutions are sent direct to weak snmps. Centrifugal pumps, when not pumping to treatment-vats, are in service circulating solution in snmps through cones for the purpose of aerating.

All potassium cyanide used in the treatment of sand, is dissolved in a small vat from which a 2-in. pipe-line is connected to the suction of a 4-in. centrifugal pump used to pump solutions on sand. By means of a table and float arranged on the vat, the desired strength of solution can be obtained by opening the 2-in. line and allowing the requisite amount of standard solution to be drawn through the pump with the weak solution from the weak sumps.

The slime plant has eleven 3-in. redwood vats 36 ft. diam. by 20 ft. deep for collecting and agitating slime; one vat of the same dimensions used in connection with the Butters filters for stock pulp, two Butters filter-vats containing 96 filter-frames each and two tanks 24 ft. diam. and 12 ft. deep used for weak solution and water for washing slime on filters.

All of the 11 vats mentioned above are provided with rim overflow launders for receiving the clear overflow when collecting slime. The overflow goes to any of the three sump-tanks, 40 ft. diam. by 8 ft. deep, from which it is returned to the battery storage-tank by means of an 8-in. centrifugal pump. Eight of the eleven vats are provided with mechanical arm-agitators driven by a 30-hp. motor with gearing and friction-clutches over each vat. Agitators make 5 rev. per min. There are two sets of four-arm agitators quartering. The lower set, to which drags are hung for keeping the heavier fine sand in suspension, is 2 ft., and the upper set 8 ft., from the bottom. Any of the eight vats can be used for agitation although at present but four are in use at the same time, leaving four of the agitation-vats and the three regular collectors for service in receiving and collecting the slime in the slime-bearing solutions. A charge of slime is drawn from the bottom of the collecting-vats by means of an 8-in. centrifugal pump without interrupting the collecting.

Previous to receiving a charge of thick pulp from the collectors, about 150 tons of barren solution is pumped into the agitator. To this is added 1,000 lb. slacked lime and 600 lb. dissolved cyanide; the whole is agitated for one hour by the mechanical agitators and pumps. The charge of thick pulp is then pumped in. When thoroughly mixed, it has an average specific gravity of 1.144, that is, 21 parts of slime to 79 of solution. The mass is agitated for 30 hours, the mechanical agitation being assisted by compressed air, admitted through a perforated pipe running half across the bottom of the vat and by an 8-in. centrifugal pump, taking pulp from the bottom and discharging at the top of the vat. This is used when not in service for other pumping. At the end of 30 hours, the agitation is stopped and the pulp allowed to settle for six hours, when about five feet of clear solution is decanted and run to the storage-vats for precipitation. The settled slime is then pumped to a second agitation-vat into which solution equivalent to that decanted has been pumped; agitation is continued for 24 hours, when the contents are delivered to the Butters filter stock-vat.

The following table gives the average time of each operation in the Butters filter, from filling the vat to discharging the cake.

Running back wash to vats.....	30
Pumping discharged slime.....	10
Total.....	185

Pumping in connection with the Butters filters is done by an 8-in. centrifugal pump, driven by a 20-hp. motor.

Vacuum for the filters is supplied by a 10 by 10 in. duplex vacuum-pump, driven by a 15-hp. motor. All valves in connection with filtering operations are operated from a platform by a system of rods and levers. The first solution coming through the vacuum-pump, upon beginning a new cycle of operations, is turbid and goes to the circulation sumps. When the solution becomes clear, usually in five minutes, it is turned to the storage-vats for precipitation.

The thick slime-cake, having been discharged, is broken up for pumping by means of 1-in. jets of water under a 70-ft. head directed downward into the hopper of the filter-vats. A duplicate pumping system is being installed to make it possible to either diminish the time of a cycle of operations or allow more time for washing. A large launder for running back wash-solution will also change the time when completed.

A mixture of air and water was tried for discharging cake but it was found that without careful attention and manipulation too much pressure would be used by the operator, thereby breaking the stitching in the filter-leaves. Accordingly, the cake is now discharged in the wash-solution by admitting water under a 12-ft. head. The wash-solution is allowed to settle for about five minutes before running back and then is drawn off to within about six inches of the thick slime in the hopper. By this means and the small amount of water from the jets, the slime can be easily pumped out with a moisture contents of 60%. At the present time, an average of 125 tons of dry slime is being filtered and discharged per 24 hours.

All solutions for precipitation are collected in two tanks, 24 ft. diam., 8 ft. deep. From these the solution is pumped through a 4-in. Worthington meter to the zinc-boxes by means of two 3-in. Byron Jackson centrifugal pumps, directly connected to 2-hp. motors. The precipitation room has a concrete floor sloping to a sump for drainage and collection of any drips or leaks.

There are fourteen zinc-boxes made of three-inch redwood. Each box has seven compartments, each holding 15 cu. ft. zinc shaving above the screen-trays, making the total capacity of the box 105 cu. ft., or about 1,600 lb. zinc shaving. The compartments of the boxes are arranged for an upward flow of solution.

The average amount of solution precipitated in 24 hours is 1,200 tons; the tailing from the zinc-boxes assays from a trace to 11 cents per ton, increasing in value from the time immediately after one clean-up to the time of the next. Four clean-ups are made each month; five men working over-time with two men from the melting-room make the clean-up of fourteen boxes in two days. During the first one the shaving in the two head compartments of the zinc-boxes is washed and the remainder moved up. The washing is done over the head compartment, and all precipitate is screened through a 30-mesh wire screen. The precipitate is allowed to settle and the solution is pumped by a 5 by 6 in. Knowles triplex pump through two Johnson filter-presses provided with 24 by 24 in. frames and leaves covered with 10 oz. duck. The settled precipitate in the zinc-box is bailed into tubs and dried in pans, without acid treatment, in a three-muffle drying furnace fired by coal. This precipitate, as well as that collected in the filter-presses, is thoroughly roasted, then pulverized and fluxed with 20 lb. borax, and 16 lb. bicarbonate of soda per 100 lb. precipitate. Formerly it was the custom to treat all the zinc-box product with sulphuric acid before filter-pressing; this practice required extra labor, expense, and time, and has been discontinued, as there was no appreciable increase in the fineness of the bullion produced.

The melting is done in six Faber du Faur tilting fur-

Stamps and Wilfley Tables at the Desert Mill.

Sumps and Extractor Boxes.

naces, equipped with graphite retorts, with a capacity of 80 lb. fluxed precipitate. Coke is used as fuel and the first pour is made six hours after starting fires. At the present time, 2,800 lb. dried precipitate is melted into bullion in 24 hr. from the time of firing the furnaces. After a charge has melted down, sufficient precipitate is added to make a bullion bar weighing about 1,200 oz. Troy. From 70,756 lb. roasted precipitate, 47,442 lb. bullion were produced; that is, without acid treatment, 67.05% of the precipitate went into bullion. This bullion had an average fineness of gold 13.5, silver 965, total 978.5 per thousand.

Pours are made directly into bullion-molds placed upon slag-pots. The molds have a slotted overflow for slag. This procedure does away with re-melting buttons into bars, made necessary when pours are made into slag-pots. The graphite retorts in the furnaces will last for about 18 fusions, when they are discarded and new ones inserted.

Owing to the fact that the crushing takes place in cyanide solution and that the sand and slime are in contact with the solution from the time they enter the batteries, it is impossible to secure trustworthy samples of sand and slime separately and keep a record of extraction by cyanide on each product. Accordingly, the difference between the gross content of the ore and the gold and silver in the concentrate shipped, is taken as the gold and silver contents going to the cyanide plant. The extraction by cyanide is estimated from this by comparing with the total ounces of gold and silver shipped as bullion and refinery by-products, with the total contents in sand and slime residues as a check. The extraction by cyanidation from March 1 to August 1, 1907, figured in this manner, is 86.06% of the gold and 80.14% of the silver contents. Combining this with the extraction by concentration, as above, 15.63% of the gold and 30.32% of the silver, gives a total extraction by concentration and cyanidation of 88.24% of the gold and 86.20% of the silver in the ore.

The average consumption of chemicals per ton of ore, for the last five months, has been: Potassium cyanide, 3.24 lb.; lime, 7.20 lb.; lead acetate, 0.38 lb.; zinc shaving, 1.10 lb.; zinc shaving consumed per ton of solution precipitated, 0.32 pounds.

Changes and improvements in the plant now under way, such as increasing the concentration equipment by better classification, increasing the Butters filter capacity and improving the present slime agitation equipment, will increase the percentage of extraction and decrease the cost of operations.

BRAZILIAN QUARTZ CRYSTALS.—There has been considerable variation in the foreign demand for crystals of quartz of large size for optical work found in Brazil during the past few years and apparently the trade is not growing. The exports of all such crystals from Brazil in 1904 was about \$46,103. In 1905 it went up to a total of \$18,132, but in 1906 it fell to a total of \$10,553. Much of this fluctuation is due to the variation in the supply. There is a vast difference in the quality of the stones found and the trade varies accordingly. Most of the best stones seem to exist in a sort of circuit ranging from the central portion of Sao Paulo through Goyaz and the western portion of the State of Minas. There is a considerable supply of smaller stones and stones of inferior quality to be had in the Rio de Janeiro market at almost any time. The best stones generally are obtained by placing orders in advance. The price given as the average for exports last year was about 42c. per kilo. (2½ lb.) but this means little in view of the great variety of stones.

Use of the Divining Rod.

Numerous devices are used throughout this country for detecting the presence of underground water—devices ranging in complexity from the forked branch of witch-hazel, peach, or other wood, to more or less elaborate mechanical or electrical contrivances. Many of the operators of these devices, especially those that use the home-cut forked branch, are perfectly honest in the belief that the working of the rod is influenced by agencies—usually regarded as electric currents following underground streams of water—that are entirely independent of their own bodies, and many people have implicit faith in their ability to locate underground water in this way.

In experiments with a rod of this type, one of the geologists of the United States Geological Survey found that at points it turned downward independently of his will, but more complete tests showed that the down-turning resulted from slight and—until watched for—unconscious changes in the inclination of his body, the effects of which were communicated through the arms and wrists to the rod. No movement of the rod from causes outside the body could be detected, and it soon became obvious that the view held by other men of science is correct—that the operation of the 'divining rod' is generally due to unconscious movements of the body or of the muscles of the hand. The experiments made show that these movements happen most frequently at places where the operator's experience has led him to believe that water may be found. The uselessness of the divining rod is indicated by the facts that the rod may be worked at will by the operator, that he fails to detect strong currents of water running in tunnels and other channels that afford no surface indications of water, and that his locations in limestone regions where water flows in well-defined channels are rarely more successful than those dependent on mere guesses. In fact, its operators are successful only in regions in which ground water occurs in a definite sheet in porous material or in more or less clayey deposits, such as the pebbly clay or till in which, although a few failures occur, wells would get water anywhere.

Ground water occurs under certain definite conditions, and as in humid regions a stream may be predicted wherever a valley is known, so one familiar with rocks and ground water conditions may predict places where ground water can be found. No appliance, either electrical or mechanical, has yet been successfully used for detecting water in places where plain common sense or mere guessing would not have shown its presence just as well. The only advantage of employing a 'water-witch,' as the operator of the divining rod is sometimes called, is that skilled services are obtained, most men so employed being keener and better observers of the occurrence and movements of ground water than the average person.

MINING LICENSES IN INDIA.—The Government of British India has decided to limit the areas granted by district officers under alluvial prospecting licenses to 1,600 acres, measuring not more than 5 miles in length except in cases of narrow belts of river gravel, on which extraordinary concessions may be granted to a length of 10 miles. The Government purposes, before the expiration of the newly granted licenses, to revise the existing general rules that govern the granting of prospecting licenses and mining leases in British India, and members of the mining community interested in the matter are invited to send to the Geological Survey department suggestions which they think should be considered before the revision is undertaken.

Mining in Australia.

Written for the MINING AND SCIENTIFIC PRESS
By W. J. LORING.

Unquestionably, never before have mining operations in Australia been conducted so extensively as today. As time goes on the miniature booms peculiar to every mining country are followed by their sequel of ups and downs in the lives of various camps. Certainly the present high price of metals is responsible to a large extent for the widespread activity, and a low metal market invariably spells corresponding periods of depression in the mining field. The following short digest is written with the intention of bettering the average American's acquaintance with Australia. The States comprising the Commonwealth will be dealt with seriatim:

QUEENSLAND.—While important mining operations

Eastern Australia.

have been carried on in this State for many years at Gympie and Charters Towers, where the mines have been worked to a great depth principally for gold, the industry has had more attention for the past couple of years than ever before in its history. Cloncurry and its environs have received special attention, and as soon as railroad facilities are established the output from this district should be an important item in the mineral wealth of Australia. The Mt. Morgan mine possesses one of the biggest copper-gold deposits in the world. It is a wonderful property, having started its career as a gold mine of enormous size and turning to copper-gold in depth, but still maintaining its huge dimensions down to the lowest level opened up. Some idea of its size may be gauged from the fact that the production from the commencement of its career in 1886 amounts to £13,000,000, out of which over £7,000,000 have been distributed in dividends. Thousands of feet of diamond-drilling have been executed to prove the future of the property, with the result that the management know what they may expect for several years to come. The mine is equipped with a very fine plant for the treatment of oxidized gold ore, a separate works for sulphide gold ore, and a third installation to

treat the copper-gold ore. Mt. Morgan is about 24 miles west of Rockhampton and is connected by railway with that town. The copper-gold industry should see great strides within the next few years in this State, particularly if the copper market holds anywhere near the present price. New copper mines are being opened up every week. The Great Fitzroy gold and copper mine is one of the most recent, and from present appearances promises to become a big producer. This mine is situated 17 miles northeast of Rockhampton. The ore bears a remarkable resemblance to that of Mt. Morgan, although the two mines are separated by some 40 miles and are not even on the same general course of country. Many promising districts throughout the northern part of the State are crying for active development, but the great drawback is the lack of railroad communication, which obviously is one of the important elements in opening and developing the existing large low-grade orebodies. The Government appears to be fully awake to the impor-

tance of this point and is lending every aid within its power to provide transportation facilities.

NEW SOUTH WALES.—Broken Hill is the most active centre in the whole State, although there are some other lively mining camps. Over 10,000 men are employed at Broken Hill, which supports a township of about 40,000 inhabitants. About 100,000 tons of ore are treated monthly at the Broken Hill mines, producing silver, lead, and zinc. The ore shows a tendency to carry a higher percentage of zinc in the lower levels than was the case in the shallower workings, and this zinc content will very much increase the value of these mines. Broken Hill is now the largest mining camp in the Commonwealth and each half-year sees a bigger yield. Good railroad facilities are available, and everything is in favor of this centre retaining its importance and present prosperity for many years. The Great Cobar copper-gold mines are steady producers and are an important factor in the mineral output of the State. Copper can be found everywhere in New South Wales, and in some places the prospects for future lucrative mining are most favorable. Under the category of gold mining, the Mt. Boppy must be given pride of place as a steady producer and regular dividend-payer. New South Wales is also a good producer of tin, most of which is won from the northern portion of the State close to the Queensland border. The enormous deposits of excellent coal stretching from

Newcastle for a hundred miles along the coast are too widely known to call for more than a passing reference here.

VICTORIA.—The rich historic fields of Bendigo and Ballarat are about worked out, and although new mines will doubtless be found, nothing of any importance can be expected as the State has been well prospected. It is of interest to note that its career began about the same time that the California diggings were opened up. Victoria is the domicile of the 'deep leads,' which have already produced much wealth, and from all appearances will continue to do so for many years to come. There are hundreds of miles of these ancient rivers yet to be opened up. One of the most recent industries is the development of the dredging system for working low-grade and shallow alluvial deposits.

TASMANIA.—This little island is richly endowed with mineral wealth. The Mt. Lyell copper and gold mine alone has a monthly output of £80,000. In tin the State is especially rich, the Briseis representing the largest alluvial mine and the Mt. Bischoff the most valuable lode-tin proposition. It is worthy of note that the latter company, which commenced its career a generation ago, has never failed to return a monthly dividend to its fortunate shareholders, the distributions to date totaling over £2,100,000.

SOUTH AUSTRALIA.—Mining is not on any large scale in this State. The old Burra Burra copper mine, which had some sensational yields in the 'fifties and shut-down thirty years ago, is now being reopened. South Australia is entitled to sympathy for its bad luck in missing Broken Hill, which is situated only a few miles within the New South Wales border. Much benefit is reaped, however, by the State having the nearest sea-front and the only railroad connection with Broken Hill. South Australia hopes yet to be the Cinderella of the Australian family, and looks to the Northern Territory to keep it. The Governor-General and several members of the Federal Parliament have recently returned from a visit to this district and speak in glowing terms of its future. The drawback in the development of the Northern Territory is its inaccessibility, or rather distance from civilization. Bordering also on the equator, the 'White Australia' policy will not make the labor problem an easy one, and such will probably always prove the fly in the ointment.

WESTERN AUSTRALIA.—The wonderful goldfields of this State, discovered in the early 'nineties by the pioneer prospectors, created a boom which was felt, not only in Australia, but throughout the whole world. While it is said that every ounce of gold produced to date has cost much more than its value, it cannot but be admitted that the discovery of these fields has been of enormous benefit to Australia and the world generally. As a rule, people do not invest money in mining unless they can well afford it, and therefore take a chance on what should be a legitimate undertaking. The wealthy investor, who can well afford to take a chance, represents the major portion of the capital required for such ventures as characterized the advent into W. A. of the proverbial 'stony-broke' prospector, the latter, in many instances, being the only one who benefited by the transaction. If the benefit was one-sided in an inverse sense, perhaps more good would result, from the fact that the capitalist would reap his reward and the prospector gain sufficient pecuniary recompense from the sale of his claim to enable him to plod on his way in search of another bonanza, in fulfillment of that innate desire possessed by every true prospector of becoming his own boss and winning a fortune from mother earth.

What could be a more legitimate way of circulating a portion of the rich man's money than to first assist and pay the prospector for his property, thereby presenting him with the means of seeking and developing new fields? The mines of W. A. have been opened up on practically these lines, and while John Bull has reaped a large benefit in many instances, he needs praise for the enormous financial assistance rendered to the State. For many years English capital was dumped into W. A. to prospect and search for new mines, but this has dwindled to slight proportions, with the effect that those small mines that counted on this support for many years have had to close down, throwing out of employment a large number of men and considerably affecting the output of gold. During the time that these changes transpired the richer and more prosperous mines had become steady producers and had perfected their surface equipment and mastered the extraction problem, which at one time was a most serious question. Their organizations were also modeled, and, on the whole, the system in vogue at present in this State sets a standard which is the envy of many mining fields outside Australia. It should be remembered that the West Australian goldfield was the most recent discovery up to a couple of years ago, when the rich fields of Nevada were found, and therefore West Australia had the advantage of avoiding, to a certain extent, the mistakes of other and older fields. The enormous richness of the region besides attracting the attention of capitalists permitted the payment of high wages, which proved a magnet in drawing the best class of workmen from the other States, with a stimulating effect on mining operations. All of these elements have counted in providing West Australia with a stable industry, which is much stronger today than is generally realized. The advantages of improved methods and high-class labor have been the means of lengthening the lives of the mines by adding hundreds of thousands of tons of lower grade ore than could have been profitably worked had the old conditions prevailed, that is, high working costs and bad extraction. The fact of the gold yield being a diminishing quantity has caused the outcry that Western Australia is fast being worked out. It is only fair, however, to compare the present tonnage treated with that of six years or more ago. No great difference is discernible except in the grade of the ore, which fact has frightened investors considerably more than the facts warrant. The West Australian Government has stood loyally by the mining industry by providing railroads, telegraphic communication, and adequate water supplies. Much criticism is hurled at the Government, but principally by people who would be discontented in Heaven. There are times of course when the service is bad, but on its attention being directed to defects, the Government is invariably ready to rectify matters.

Of new fields, Black Range shows signs of being a good district. It is situated northeast of Geraldton about 325 miles, of which all but 100 miles can be covered by rail to Mt. Magnet, one of the mining towns of the early days. The Government has greatly assisted in the exploitation of Black Range by furnishing telegraphic facilities, and has now under consideration the extension of the railroad. The Great Boulder, Ivanhoe, Golden Horseshoe, Oroya Brownhill, Sons of Gwalia, and other large West Australian gold mines continue to open up satisfactorily, but space does not permit of individual description. Ravensthorpe, whose chief industry is copper-gold mining, is one of the fields receiving considerable attention just now. It is reported that some fairly good shows are under development and a strong English company is doing a lot of work, with, it is claimed, satisfactory results.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

METHOD OF TUNNELING.—No. 867,392; David Maxwell, Detroit, Michigan.

The herein described method of tunneling, which consists in preliminarily cutting or drilling to outline the cross-section of the tunnel, and also drilling exteriorly of such cross-section at the top of the tunnel, and subsequently dislodging and removing the material contained in the outlined area and in the exteriorly drilled area; substantially as described.

INGOT-STRIPPING MECHANISM.—No. 867,311; George W. Shem and Homer W. Israel, Alliance, Ohio.

An ingot-stripper, a mohl-engaging device, a carrier therefor, an ingot stop, a carrier therefor, sheaves supported by the carriers, a single continuous rope or cable having its intermediate portion engaged with the sheaves on both carriers, and a winding means for at least one end portion of the rope or cable; substantially as described.

ORE-CONCENTRATOR.—No. 867,267; Abel Guionneau, Denver, Colorado.

In an apparatus of the class described, an endless traveling transversely vibratory belt upwardly inclined from one end toward the other and adapted to discharge mineral values from each end, the belt having transversely-disposed riffles on the outer side thereof of progressively decreasing thickness from the back toward the front thereof, a feed-box at the back of the belt between the ends thereof, and wash-water pipes extending longitudinally of the feed-box, said belt serving on its vibratory movement to discharge mineral values from the front thereof.

AERIAL TRAMWAY.—No. 867,497; Walter S. Gemmer and Emil J. Schleicher, St. Louis, Missouri.

In an aerial tramway system, the combination of a traveling bucket and a traveling loader, said loader embodying a plurality of hoppers which discharge into said bucket.

ORE-SEPARATOR.—No. 867,360; John A. Haralson, Mexico, Mexico.

Apparatus for precipitating metals from solutions, the same comprising a retort for generating gas, a gasometer for storing the gas as produced, a generator containing water and the material previously retorted, means for supplying gas from the retort to the generator and agitating the solution therein, a mixer, means for supplying metalliferous solution and the gas from the generator to the mixer in regulable quantity, and a separator receiving the metalliferous solution impregnated with the gas from the mixer to effect separation of the metal by precipitation.

SCREEN SIZING AND SEPARATING MACHINERY.—No. 864,827; John M. Callow, Salt Lake City, Utah.

In screen sizing apparatus, the combination of a frame, a water tank thereon, an endless traveling band of screen cloth, means for supporting it at its ends above such tank, intermediate means for deflecting the working portion of the band below the level of the supporting means and into the water, and means for imparting a reciprocating motion to the frame.

ELECTRIC FURNACE PROCESS OF MAKING LOW-CARBON METALS OR ALLOYS.—No. 858,780; Frederiek M. Becket, Niagara Falls, N. Y., assignor to Electro Metallurgical Co., a Corporation of West Virginia.

The process of producing low-carbon metals or alloys, which consists in smelting the charge by an electric current of high density, carried by a carbon electrode of relatively small sectional area, and cooling said electrode throughout a considerable portion of its length.

Publications Received.

'Bibliography of the Geology of Connecticut.' By H. E. Gregory. Bulletin No. 8. State Geological Survey.

'Report on the Bell Mount and Middlesex District.' By W. H. Twelvetees. Government Geologist of Tasmania.

'Chemical Reagents, Their Purity and Tests.' By E. Merck. A 250-page book, devoted to the description of reagents and methods for determining the exact degree of their purity. The D. Van Nostrand Co. Price, \$1.50 net.

'Quantitative Punctuation.' An essay in the pedagogy of English composition. By J. D. Logan. This is a suggestive and practical brochure on punctuation. Any writer will be glad to read it and to possess it. Published by William Briggs, Toronto.

'Illinois State Geological Survey. Bulletin No. 4.' In this is given the statement of the progress for the year 1906, preliminary investigation of Illinois fire clays, contributions to the study of coal, a report of the stratigraphical work near East St. Louis, and mineral statistics for Illinois for the year 1906.

We are in receipt of the following publications of the United States Geological Survey: 'Bulletin No. 304; Oil and Gas Fields of Greene County, Pennsylvania.' By Ralph W. Stone and Frederick G. Clapp. 'Bulletin No. 311; The Green Schists and Associated Granites and Porphyries of Rhode Island.' By Benjamin K. Emerson and Joseph H. Perry. 'Bulletin No. 317; Preliminary Report on the Santa Maria Oil District, Santa Barbara County, California.' By Ralph Arnold and Robert Anderson. 'Bulletin No. 318; Geology of Oil and Gas Fields in Steubenville, Burgettstown, and Claysville Quadrangles, Ohio, West Virginia, and Pennsylvania.' By W. T. Griswold and M. J. Munn. 'Bulletin No. 320; The Downtown District of Leadville, Colorado.' By Samuel Franklin Emmons and John Duer Irving. 'Professional Paper No. 53; Geology and Water Resources of the Bighorn Basin, Wyoming.' By Cassius A. Fisher.

We have received the following advance chapters from the Mineral Resources of the United States for 1906: 'The Cement Industry,' by Edwin C. Eckel; 'Gypsum and Gypsum Products,' by Ernest F. Burchard; 'The Production of Precious Stones,' by Douglas B. Sterrett; 'Asbestos,' by J. S. Diller; 'Mica,' by Douglas B. Sterrett; 'Phosphate Rock and Phosphorus,' by Myron L. Fuller and George W. Stone; 'Asphalt and Bituminous Rock,' by Joseph A. Taff; 'Quartz (Flint) and Feldspar,' by Edson S. Bastin; 'Monacite and Zircon,' by Douglas B. Sterrett; 'Anthracite Coal,' by William W. Reiley; 'Fluorspar and Cryolite,' by Ernest F. Burchard; 'Barytes,' with a note on 'Strontium,' by Ernest F. Burchard; 'Bauxite and Aluminum,' by Ernest F. Burchard; 'The Production of Nickel, Cobalt, Tungsten, Vanadium, Molybdenum, Titanium, Uranium, and Tantalum in 1906,' by Frank L. Hess. In this are given not only the statistics concerning these metals but also a statement of the experiments and investigations of these metals during the year. 'The Production of Mineral Waters in 1906,' by Samuel Sanford. In this are given statistics of the sale of such waters, the trade conditions in that industry, and the locality of the important mineral springs of each State. 'Water Supply and Irrigation Paper No. 198. 'Water Resources of Kennebec River Basin, Maine,' by H. K. Barrows, with a section on the 'Quality of Kennebec River Water,' by George C. Whipple. In this is an interesting chapter on water pollution with especial reference to the transportation of typhoid germs in surface waters.

STEEL FOR MANCHURIA.—A steamship sailed from New York recently with a 12,000-ton cargo of steel equipment for the Manchurian railroad, furnished chiefly by the United States Steel Corporation. Within the next 12 months 163,000 tons of rails, 8,000 tons of bridges, 250 locomotives, and 3,000 cars will be shipped to Dalny, the principal seaport terminus of the South Manchurian system.

Catalogues Received.

THE PACIFIC TANK CO. issues a little folder describing the Hampton improved zinc lathe No. 3.

THE CYCLONE DRILL CO., of Orrville, Ohio, is sending out an attractive folder entitled 'Cyclone Blast Hole Drills and Loaders.'

SAM'L K. BEHREND, 1711 California St., Denver, Colo., manufacturer of the Behrend dry concentrator, has issued a useful description of that machine.

THE H. W. JOHNS-MANVILLE CO. of New York has issued a folder called Catalogue No. 110, on 'Morris Metallic Packing,' for which this company is the sole selling agent.

THE ARTHUR KOPPEL CO., of Pittsburg, has issued Catalogue No. 227 on 'Portable and Industrial Railways.' It illustrates the simplicity and usefulness of the Koppel system.

THE BROWN HOISTING MACHINERY CO., of Cleveland, Ohio, has just issued an attractive circular dealing entirely with ore-handling locomotive cranes, which should interest mining men.

THE HOSKINS CO., of Chicago, is sending out a preliminary announcement of the 'Hoskins Electric Furnaces.' This is a new departure and further announcements will follow.

THE JEFFREY MANUFACTURING CO., of Columbus, Ohio, has issued Catalogue No. 69 A., entitled 'Jeffrey Screens,' and contains illustrations of every type of screen manufactured by this company.

THE ALLIS-CHALMERS CO. has just issued Instruction Book No. 5010. In this are given full and explicit instructions for installing and operating Allis-Chalmers 'Direct Current Motors and Generators, type H, H I, and I.'

THE FORT WAYNE ELECTRIC WORKS, of Indiana, sends us Instruction Book No. 3,028 on Type K single-phase integrating induction wattmeters; also Bulletin No. 1,098, on Type M P L belted generators for light and power, and Bulletin No. 1,100, on small direct-current motors, Type L.

THE J. GEO. LEYNER ENGINEERING CO., of Denver and Littleton, Colo., has issued a catalogue describing their ore handling apparatus; also Bulletin No. 512, and Bulletin No. 510. The first mentioned covers cars, skips, buckets, cages, tanks, derricks, sheet-iron work, etc. Bulletin No. 512 treats of the Model No. 6 Water Leyner rock-drill; No. 510 contains 56 pages on steam and electric hoists, giving horsepower, size of wire rope to use in hoisting, and size of electric wire used on their machines. Each one of these catalogues is complete in itself and will be sent on application.

Commercial Paragraphs.

THE DURYEA MANUFACTURING CO. of New York, has recently made an agency agreement with Barton Squires & Byrne, 531 Howard St., San Francisco.

THE WM. POWELL CO. announce that the increasing demand for their steam engineering specialties has compelled them to enlarge their plant by an addition of 200 horsepower.

THE ROBINS CONVEYING BELT CO. will, on October 1, remove their main office from the Park Row Bdg., New York, to Passaic, N. J. At Passaic they have recently constructed a modern office building adjacent to their works. This move is necessitated on account of the large business they are doing, which calls for more commodious quarters than were available in New York.

THE POWER & MINING MACHINERY CO., of Cudahy, Wisconsin, announces that, owing to the increase of business on the Pacific Coast, it has opened an office at 148-150 First St., San Francisco, where it will carry a full line of mining machinery and supplies. E. C. Hutchinson, at one time with the Union Iron Works, and recently at the head of the mining machinery department of the Charles C. Moore Co., will be in charge.

Editorial.

G OVERNOR HUGHES of New York has dared to deny the right of the owner of 51 per cent of the stock of a corporation to do what he pleases in the management of its affairs, and he has even ventured to add that the policy of such a majority must be "consistent with good faith and fair dealing to all." We are glad to see such an expression of opinion. It is high time that the control of a majority of the stock, or proxies from a subservient minority added to the small holdings of an unscrupulous financier, should cease to carry with it the right to loot. Directors are trustees, not licensed looters.

WE TAKE PLEASURE in quoting at length on another page from an article by Mr. James Douglas on 'The Copper Situation,' appearing in the current number of *The Engineering Magazine*. It is not necessary to emphasize the position held by Mr. Douglas in the copper industry nor to tell our readers that anything he says is worth listening to. In his summary of the present status of the copper mining industry he has made clear the basic facts and given a large amount of information of particular interest at this time.

IN RECENT CORRESPONDENCE from the Cœur d'Alene region, reference has been made to the suits between Mr. Jonathan Bourne Jr. and the Sierra Nevada Consolidated Company, now pending in the District Court at Wallace. The general impression is that this is a controversy between the Bunker Hill & Sullivan Company and the Federal Company. It is well therefore to state that the Bunker Hill & Sullivan Company is in no way connected with this litigation, Senator Bourne having been the owner of the ground in question for nearly twenty years, and the case is being conducted in his own behalf and at his own expense. It happens that Mr. Stanley A. Easton has acted as advisory engineer to Senator Bourne, and Mr. F. A. Folsom, one of the attorneys of the Bunker Hill & Sullivan Company, is also attorney for the Senator. From this coincidence the idea has grown that the big mine at Wardner is involved in the particular litigation mentioned. The misunderstanding is worth correction.

NEW YORK papers, even the best of them, exhibit impatience with the Presidents' speeches and vent their displeasure in satirical comment. They object to being "harangued" by Mr. Roosevelt and they marvel at the enthusiasm with which great audiences greet him. As we happen to live far from Wall Street and State Street, and from the stock speculation that makes men dependent upon the doings of a few restless financiers, we do not marvel at the influence exerted by the President and the interest taken in his utterances. Mr. Roosevelt

makes some blunders, like any other impulsive man, and he plays politics, as do most leaders of a party, but the American people delight in the evident sincerity of his purpose, the frankness of his speech, and the forcefulness of his attitude on matters that need all of these qualities. There are other men of equally strong fine character in this country, otherwise it were in a bad way indeed, but it so happens that none of them are in a position to make themselves such a living power for good as the President. His popularity may suffer, especially among those to whom his antagonism to predatory finance seems more radical than safe. His speeches may be frequent and too minatory. But assuredly the American people will continue to thank him for rallying all that is best in this Commonwealth to the defence of laws too long outraged and to the support of civic ideals too long smothered by rampant individualism.

The Stock Market.

THE SPECULATIVE CRISIS of the past week will have proved a matter of concern even to those least affected by the gambling operations on Wall Street and State Street, for when the dust created by falling pyramids has cleared the financial arena will be strewn with the wrecks of ruined lives, and that is sad enough, however amusing the vagaries of the plungers may have been. The plight of Heinze and his friends will provoke no more sorrow than surprise, for he has ever been an unscrupulous gambler, no worse than many others and more picturesque than most, but still an evil influence in the mining industry. Moreover, he is young and not easily daunted, so he has a future. We hope it will be more reputable than his past. But one of the real captains of industry whose name is on everyone's lips today is George Westinghouse. Without any special knowledge of Mr. Westinghouse, we have every reason to regard him as one of the few mechanical and financial geniuses that have not prostituted great talents to financial piracy. He is honored as a man and respected as the leader in tremendous industrial activities. He belongs to the best type of clever, self-reliant, progressive Americans, and we regret that financial embarrassment should have resulted to him at this time. Another name is mentioned as that of a financier likely to be compelled to retire from an autocratic position. We refer to E. H. Harriman. It would be a splendid tribute to the strength of public opinion if this grand larcenist were forced to resign from the trusteeships that he has dishonored. No worse influence exists in American life today than the unscrupulous jobber who is at the head of several great railroad systems. Such men as Harriman, Rogers, Ryan, and the traction looters of Philadelphia and New York represent the most vicious development in industrial civilization. The sooner they are recognized at their true worth, the better for representative government in America. If the tumble in stock quotations leads to the elimination of some of these undesirables, it will be well.

No heed should be given to those who attribute the débâcle to the speeches of the President. Mr. Roosevelt's

outspoken criticism has been directed against dishonest practices, and it has coincided with a period of reaction. A coincidence is magnified to a consequence. By reference to the quotations current in October 1904, we find that some of the leading stocks stood at that time as follows: Amalgamated, 62; American Smelting, 65; Union Pacific, 104; United States Steel preferred, 77; Calumet & Hecla, 550; Wolverine, 96; United Copper, 5 to 8. Compare these figures with the prices of this week and it will be found that they stand on a close parity with those of three years ago, which means that the crash of the past ten days has been due mainly to the expulsion of aerated warm water. It has not been caused by legislative or inquisitorial action at Washington or elsewhere. A period of excessive speculation has come to an end, a few reckless gamblers are ruined and in their wreckage they have pulled down much better men, including many innocent and ignorant investors. In the meanwhile the country is all right and the industrial development of it will continue, despite the betting on stocks. A few gentlemen who were carried forward on the crest of a great wave of prosperity had begun to think that they made the wave. They are now like the seaweed that is left by the receding tide, which ebbs and flows, but does not disappear.

The Barnes King Affair.

OUR CORRESPONDENT at Butte has referred to this fiasco in his recent letter. Many features of the affair are difficult to understand; but one of them we can make clear. Among the professional men mentioned as having reported favorably on this much over-rated mine is Mr. Walter H. Weed, one of the foremost geologists in America. We wrote to him asking him to state in what way he was connected with the flotation. His telegraphic reply arrived after we had gone to press last week, therefore we are glad to give his answer the fullest publicity possible by publishing it herewith. His telegram says: "I have never made examination for, nor had any connection with, Barnes King mine or promoters thereof; I made a preliminary geological examination without measurement or sampling for some private clients, who thereafter declined option; and neither report nor any part thereof has been given out. Have never even visited the Clipper group or that district. The use of my name in either connection is wholly unwarranted and libelous." It is a great pleasure to be able to do this measure of justice to an honorable man, especially as some of our contemporaries have gone astray. *The Mining World*, a Chicago periodical, says, very truly, that "all that glitters is not gold" and then adds, most wisely, that this is another example of "frenzied finance." In assuming Mr. Weed to be blameworthy, the Chicago paper refers to its "editorial correspondence;" this is misleading, for that so-called "editorial" correspondence will be found in our issue of October 12, only there it has been edited, while in *The Mining World* it is given verbatim as sent to us from Butte by our regular correspondent. However, that is by the way. The Barnes King is now in

good hands, namely, those of Messrs. John Gillie and C. W. Goodale. They will protect the bewildered stockholders. It is odd that such men as John D. Ryan, John Gillie, and C. W. Goodale should have gone into an enterprise that turned out such a fraud and it is presumable that they were misled by the report of an engineer formerly in the employ of the Amalgamated. If, in addition to their recent service to the stockholders, they will state frankly how they themselves were deceived, it is likely that the fiasco may serve at least as a warning to the public, both lay and professional.

In the meanwhile we may point out that this is not the first time that geological investigations have been dragged into the vortex of a flotation. Several of the officers of the United States Geological Survey have found their scientific descriptions of mineral areas used as frills to decorate the masquerade of financial chicanery and they have been powerless to prevent such injury to their reputations. In such cases it is well to explain the matter frankly to their friends and this they can do most effectively in the pages of the engineering periodicals. A man whose reputation is clear in the eyes of his own profession, need not bother about the public. That blundering entity must get its rating of engineers and geologists from their peers, that is, from the members of their own profession.

Dredging at Dawson.

WE ARE INFORMED that the placer mining operations of the Guggenheims at Dawson have been stopped, owing to the financial stringency at New York. Although not much has been said about the matter, it is understood that the Guggenheims have expended about \$7,000,000 in the purchase of alluvial ground near Dawson, and that they have taken up practically all of Bonanza creek, including the bench gravels of the so-called White Channel. Some of the lower ground will be worked by dredges, while the higher benches will be hydraulicked, it being expected that the natural thaw will permit of this method of mining. For the last two years the Guggenheims have been engaged in construction work on a large scale, including a ditch 53 miles long, with two siphons, to bring 5,000 inches of water from Twelve Mile creek. An electric plant has been erected, and the dredges will be operated by it. During the past season three dredges have been at work and the material for four more is on the ground or partially assembled. It is also stated that the same financial group has bought the control of the White Pass railroad, which connects Dawson with the coast at Skagway.

It remains a moot question among engineers as to what extent frozen ground can be worked profitably, despite the undoubted high content of the gravel in that part of the Yukon, for an average yield of a dollar, or even more, is not at all unusual. Dredging is still an experiment under Arctic conditions, but the outlook is promising. The first dredge in that part of Alaska was one of the New Zealand type, which was erected in 1898 on the Lewes river in the Yukon. Subsequently it was taken apart and removed to Dawson, and placed on the Discov-

ery claim, where it proved most successful. Then the Rothschilds of Detroit built a dredge at the mouth of Bear creek. This installation cost \$300,000; it was operated by electricity and it proved a distinct success, the yield being fully \$1 per yard. It was a Marion steam-shovel, and was erected in the short space of 51 days. The daily capacity was 3,500 cubic yards. The success of this plant called attention to the district for dredging purposes, and led to the incursion of the Guggenheims, with the results stated above.

If the frozen ground can be worked successfully, there will be a tremendous lot of gold taken out within the next few years. Of course, frozen ground cannot be blasted. Anyone who has tried will know why. Then steam points were introduced for thawing. They consist of a hollow pipe of 1½ inch diameter and 20 feet long, making way for a ¾ inch pipe, through which the steam is led. But this method is costly, and in working on a large scale, it is expected to make the most use possible of the natural thaw. When the muck and moss that covers the surface are removed, the thawing will proceed at the rate of six to ten inches per day, on a vertical face, such as that of the bench gravels. It is said that on a sunny exposure the seasonal thaw will amount to as much as 15 feet, but even this may not be sufficient to reach the bedrock, on which most of the gold lies. In the creeks, the thaw may extend to the water-level, but there it stops, for the water being just below the freezing point, creates an obstacle to further melting of the ice binding the deeper gravel. However, these are problems new in placer mining, and we hope that the next year or two will yield much valuable experience, some of which we expect to record in these columns.

REEINFORCED CONCRETE is being used on an enormous scale in the rebuilding of San Francisco. Apart from the variety of reinforcement used, and the quality of the cement, it is not too much to say that the excellence of the work performed differs to a degree not altogether pleasant to contemplate. Rigid inspection is hardly to be expected, and municipal control of construction is not yet sufficiently advanced to make inspection altogether reliable. The best inspector is Mr. Earthquake, whom you cannot bribe, and who is not in politics nor in a labor-union. On April 18 of unpleasant memory he found several defects in the buildings of the city; it were well to be always ready for such casual inspection as he may make without formal notice. In the meanwhile the following note may prove suggestive to those engaged in the work of reconstruction: In cement the two principal substances of definite composition are alite and celite. The former exists as well defined crystals, the latter as a matrix or interstitial filling. When excess of 'gage-water' is used and the cement is allowed to stand, alite separates out on the surface, which is weaker than the mixture of alite and celite; hence in the use of cement where excessive gage-water is used, if a period elapses between two successive pourings sufficient to admit of final set, the newly added cement bonds upon a line of weakness.

Personal.

H. V. WINCHELL has been to Bisbee.
 MARTIN J. HELLER is at Cripple Creek.
 THOS. T. READ is here, on his way to China.
 ALBERT BURCH is at Virginia City, Nevada.
 L. C. WYNNE is at Hedley, British Columbia.
 COURTENAY DE KALB has returned to Los Angeles.
 E. A. LONG, of Ouray, Colorado, is in San Francisco.
 R. C. N. TWITE has returned to London from the Caucasus.

DUDLEY BAIRD has returned to San Francisco from Spokane.

ROSS B. HOFFMAN has returned to San Francisco from Alaska.

D. C. BARD, of Butte, has been on a visit to Salmon City, Idaho.

SAMUEL NEWHOUSE has been called to New York from Salt Lake.

C. D. KAEDING has returned from Korea and is in San Francisco.

C. T. DURELL sailed on the *Manchuria* on his way to the Philippines.

VICTOR G. HILLS has returned to Denver from Guanajuato, Mexico.

C. W. MERRILL is visiting his home in Alameda, near San Francisco.

FRANK H. PROBERT has returned to Los Angeles from a holiday in Europe.

RICHARD B. STANFORD is at Colorado Springs, on his return from Nicaragua.

ROBERT SIBLEY, of Spokane, is at Oroville studying methods of gold dredging.

E. L. BALLOU has left Pony, Montana, and is at Igo, in Shasta county, California.

B. N. LEHMAN, of the Yankee Con. mine at Tintic, is in Siskiyou county, California.

J. A. HOPPER has returned to San Francisco after several months holiday in England.

J. C. RALSTON, of Spokane, who has been seriously ill, is convalescing satisfactorily.

ARTHUR D. YOUNG is making a survey of the Green Gold-Silver Co.'s concession in Sonora, Mexico.

C. C. WILSON has opened an office at 22 Second St., San Francisco, to engage in general engineering practice.

DUNCAN MACVICHIE, managing director of the Bingham Consolidated and other Heinze enterprises, has gone to New York.

R. J. HAWKE, formerly with the El Progreso Mining Co. at Triunfo, Lower California, is now superintendent of the El Cobre mines of the Douglas Copper Company.

FRANK BAIRD, smelter superintendent for the Penn Copper Co., at Campo Seco, is convalescing at his home in Berkeley from a serious injury received while operating a slag-train.

R. H. SUTTON, superintendent of the Cocopah Copper Co., who has been spending the past month at Los Angeles, has returned to the mines at Ivanpah, San Bernardino county, California.

J. B. TYRRELL, who for the past eighteen months has been mining engineer for Mackenzie, Mann & Co., owners of the Canadian Northern railway, is now prepared to do a general consulting business. His office is still at 9 Toronto St., Toronto.

A. L. MCCARTY, until recently general superintendent for the Comanche M. & S. Co., at Silver City, N. M., J. W. CROWDUS, superintendent for Eckles & Co., at Chloride Flats, N. M., and chief engineer to the Comanche Co., and E. P. MCCARTY, assistant professor of mining engineering in the University of Minnesota, have opened offices as engineers at El Paso and Minneapolis.

General Mining News.

ARIZONA.

GRAHAM COUNTY.

The wagon-road to the Bacon & Landerman claims, near Morenei, has been finished and shipments to the Shannon and the Douglas smelters have been resumed. The development work on the claims is so encouraging that Bacon & Landerman have bought several adjoining claims.—The recent strike at the Buzzard Shadow is still looking well.—Considerable development work is being done on several groups of claims near Copper creek; these ores carry copper and gold. The development has already reached the sulphide ore below the surface carbonates.

MOHAVE COUNTY.

Another strike of rich galena has been made on the De la Fontaine mine at Stockton Hill. The vein is three feet wide.—The White & Howell roaster at the Vanderbilt mill is almost completed. The mill will start as soon as the roaster is finished.—The mill at the Oro Plata is about finished; some of the machinery, which was shipped six weeks ago from Chicago, has not arrived as yet, and so the starting of the mill is delayed.—The Pyramid mine and mill has been shut-down until heavier machinery, which is to be driven by electricity, can be installed. This mine has been a very large gold producer.—The shaft at the P. K. mine, in I X L basin, is being sunk deeper. The ore in it looks better than that in the upper cross-cut.—Owing to the wash-out of the water-line from Little Meadows to Goldroad and the inability to get oil for power, the Gold Road Co. has been forced to close down the mill. A large electric compressor has been ordered for the mine. A tube-mill is to be installed and the mill enlarged during this shut-down.

YUMA COUNTY.

The Boone copper mine in Cunningham Pass, near Wendendale, has been sold to Nevada mine operators. This property was discovered in 1863 by Cunningham, the old pioneer after whom Cunningham Pass was named. The shaft on the property is down to water-level and the recent purchasers have been shipping ore for several months.—The King of Arizona M. Co., operating about 45 miles from Mohawk, is working 150 men at present, while 50 men are hauling freight and wood. The shaft at the mine is 750 ft. deep, being sunk at an angle of 65°. The main tunnel, which gives 250-ft. backs, is 200 ft. long. The mill is supplied with water from two bored wells 1,100 ft. deep. The ore is crushed dry in breakers and rolls and then cyanided without amalgamation.

CALIFORNIA.

BUTTE COUNTY.

The wagon road from Oroville to the Cape Horn drift mine is about half finished. Work is being pushed at the mine where the recently found channel is being developed. W. M. Wilson is manager.—The union recently organized by the dredger men has a membership of over 150 men. It is reported that the winemen will ask for \$3.50 per day and the oilers for \$3, this being a raise of 50c. per day. No formal demands have been made as yet; the dredging companies say that they can not afford to pay any such increase in wages.

EL DORADO COUNTY.

The Green Valley Mining Co. is preparing to work the placer gravels on the Dormody ranch above Folsom. A contract has been let for the erection of a \$10,000 plant. A new method will be used in mining this deposit. Pumps will be used to create pressure for the hydraulics, which will work in pits from which the gravel is elevated to the sluices; these sluices will be placed so as to return the tailings to the ground which has been already washed. This mine will probably be working about the first of next year.—The old Atlantic mine near Placerville is being sampled.—The Lovless brothers have found another body of ore in their mine near El Dorado. This mine produced \$20,000 from the ore-shoot which was found several years ago.—The shaft

at the Poundout gravel mine is down 80 ft. and will reach the channel at a depth of about 50 ft. more.

KERN COUNTY.

A telluride ore has been found on the 500-ft. level of the Sunshine mine at Randsburg. The ore is of high-grade and there appears to be considerable of it.

NEVADA COUNTY.

(Special Correspondence).—It is rumored that the Idaho-Maryland will resume operations at an early date.—Sinking is rapidly progressing at the Central Shaft, good progress being made.—The shaft at the Kenosha is being rapidly unwatered, and it is thought that active operations will commence in a few days. The ore from this property will be handled at the California mill, pending the installation of a plant by the Kenosha Co.—The rich strike recently made in the Gold Mound is holding out well, and the vein is giving good indications of permanency.—The vein at the Conlan has narrowed to a small stringer, and considerable driving is under way, in hopes of striking a larger and richer orebody. A 10-stamp mill was recently installed at the mine.—Rich ore is being taken from the shaft of the Aurora mine at Randolph Flat, and much active development is under way.—Development is progressing steadily at the Union Hill mine, and the management is well pleased with the showing thus far made.—At the Pennsylvania-W. Y. O. D. mine some good ore is being developed. Operations are being carried on principally through the W. Y. O. D. workings. Bennet Opie is superintendent.—At the Champion-Home mine, at Nevada City, splendid ore is being taken from the lower levels, and the 70-stamp mill is running constantly on good ore. The rich vein recently struck on the 300-ft. level in the Champion is showing up splendidly, and large quantities of rich quartz are being extracted. The Home shaft has reached the 800-ft. level, and a large area of virgin territory is being developed.—The vein recently struck in the Austin mine in Willow Valley is improving with development. The mine was recently inspected by W. S. Beard, F. Meyn, and William Rose, Kansas City, Mo., capitalists, who are interested in the property.—Active operations will commence at the Phoenix mine at Gold Flat in the course of a few days.—W. P. Martin, superintendent of the Gold Flat mine, has struck a rich shoot of ore in his lease on the Golden Gate. A large force of men will be put to work to thoroughly develop the vein, while a pumping and hoisting plant will be installed.

Grass Valley, Oct. 21.

Work has begun at the Nevada County Midas Co. property on Randolph Flat. The new shaft will be sunk at an angle of 60° near the old shaft; it is to be 10 ft. 5 in. by 5 ft. 5 in. in the clear. A payment on the adjoining Davis property has been made by this company. The Aurora, Dolly Madison, Kenosha, Gold Mound, and California mines are all on the same mineral zone as the Midas. The old Baltic mine has been bonded by G. W. Root, general manager of the Kenosha, and work has begun there in the hope of tracing the Midas lode into that claim.—At Meadow Lake the Union and the Excelsior Con., locally known as the Hartley properties, have been sold to the Excelsior Consolidated Mining Co.—A large body of gold-bearing quartzite has been found in Fairview mine, near Relief hill.—The Golden Gate mine at Grass Valley has been reopened, and some good ore has been found.—A good surface showing of galena has been found on some claims in the southern part of this county. This is the first vein of galena found in Nevada county.

PLUMAS COUNTY.

(Special Correspondence).—A strike of gravel running \$400 per ton is reported from the main tunnel in the Bellevue. Considerable work is under way.—At the Claybank considerable prospecting is under way in an endeavor to find the main channel. J. M. Thomas is superintendent.—A 7-ft. vein of excellent ore has been struck in Tunnel No. 3, at the Copper Hill. The mine is one of the properties of the Con. Copper-Gold Co.—Good ore has been encountered in the upper levels of the Five Bears,

and the mine is showing up well. Development has exposed several promising shoots of ore.—A 7-ft. vein of ore assaying \$500 per ton has been struck in the main tunnel at the Plumas National mine, seven miles from Greenville. The tunnel is in 1,500 ft. and the vein has been proved several hundred feet. Large quantities of high-grade copper ore are being developed in the Eagle mine, in the Genesee district. The main tunnel is in 200 ft. with 600-ft. backs. Several veins near the surface are being developed. John and William Huesmon are developing several claims, which adjoin the Eagle. Ore carrying gold, silver, and copper, which assays from \$10 to \$34 per ton is being taken from shoots near the surface. Prospect shafts have been sunk and the ore is also exposed by cuts.—The Plumas-Mohawk Co. is developing a group of rich gold claims near Johnsville. A mill with a capacity of 200 tons per day is being erected; this will be operated by water power.—Rich ore is coming from the Jamison mine, and extensive development is under way.—At the White Lily six stamps are dropping on good ore.—At the Gruss mine rich ore is being taken from the upper levels, and the 5-stamp mill is running full time. Since its discovery the Gruss has produced about \$500,000 from numerous gopher holes. The Feather River Placer M. Co. is driving a tunnel on the Scott claim to intersect the Sunnyside and Dutch Hill channels.—Nevada capitalists have had the Hilda and adjoining properties examined by engineers and it is expected that the properties will change hands shortly.—Several companies are preparing to operate extensively on Poorman's creek during the coming winter. Nevada corporations are particularly active. Reno people have acquired control of most of the leading gold and copper properties throughout the Genesee, Last Chance, and Ward Creek districts.

Quincy, Oct. 17.

SHASTA COUNTY.

The vein in the Midas mine at Harrison Gulch has been recovered in new ground on the 1,100-ft. level; the vein is said to be of good grade. About 35 men are working at the mine but the force is to be increased soon.—Owing to the low cost of copper, all the large copper mines and the smelters of Shasta county have shut down. This throws 1,000 men out of work and stops a monthly payroll of \$125,000. Among the mines that have shut down are the Shasta King, the Trinity, the Balaklala, and the Mammoth, but in addition many quartz mines of this and Trinity county, which have been furnishing fluxing ore to the smelters, will also have to close down.

SIERRA COUNTY.

The first clean-up at the new 5-stamp mill at the Papoose mine in Jim Crow canyon near Downieville was quite satisfactory; about 200 tons were crushed during the run.

TRINITY COUNTY.

The Globe and the Chloride gold mines near Weaverville have been sold to W. H. Pinkston for \$150,000. Richard James has been appointed superintendent. The two mines will be worked jointly. Formerly it has been impossible to work the Globe into the winter owing to heavy snow fall, but the Chloride mine on the south side of Globe Mtn. can be worked all the year. It is intended to work the Globe through the Chloride mine and so keep both in operation the whole year. The Chloride mine was a large producer several years ago, but the ore petered out. The mine then employed 100 to 150 men and the 20-stamp mill and cyanide plant was kept busy. Eight or ten men have been kept on development since and considerable ore has been opened up. The vein at the Globe mine is about 12 ft. wide and is of good grade.—A 9-ft. vein of ore has been found on the 110-ft. level of the Gold Standard mine, 14 miles west of Carville.—The Sykes mines at Trinity Center is employing 20 men; T. McDonald is superintendent. The ditches and flumes are being repaired and everything put in readiness for hydraulicking this winter. The dredger which has been working at Trinity Center for the past few years is being dismantled and a larger and stronger one will be built. Clary & Payne, the owners, are working some gravel in the sluices; the gravel is hoisted from a shaft

which they have sunk in the gravel near the river.—The mill at the Bonanza King mine is being run full time but not at its full capacity; 65 men are employed at the mine and mill.

TUOLUMNE COUNTY.

Wages have been raised voluntarily by the owners of the Mack mine, near Groveland. Muckers will receive \$3 per day; single jackers, \$3.25; machine men, \$3.50; all miners work eight-hour shifts.

COLORADO.

SAN JUAN COUNTY.

The Frisco Mines & Tunnel Co. is driving the Bagley tunnel to tap the old Red Cloud workings and other well-known veins in the vicinity. The tunnel is now 3,850 ft. in length; they have about 1,200 ft. farther to drive before reaching the Red Cloud. When the tunnel is completed through the mountain it will extend into Ouray county. They are using Ingersoll Sluggers, also Leyner No. 6 drills and the Waugh drills. They recently cut three blind veins but have developed them but little. One of the veins is considered to be of workable grade but the other two have not been developed sufficiently to state how good they are. A Franklin compressor has been recently installed. The railroad is surveyed to the tunnel entrance, which is about three-fourths of a mile from the terminus at Animas Forks. O. B. Clarke, superintendent; N. R. Bagley, manager, and D. R. Reed, consulting engineer.—The California Mtn. Mining Co. is driving an adit into California mountain; about 400 ft. farther ought to cut the Mountain Queen vein, the objective point. The adit is now over 1,400 ft. in length. Ingersoll drills and a Rand compressor are used in doing the work. A. H. Kunkle is superintendent.—The big Gold Prince mill is operating 70 stamps at present, but within a short time expects to be running full capacity. The mill contains 100 stamps, 70 Card concentrating tables, and 5 tube-mills. The machinery was supplied by the Denver Engineering Works of Denver. M. O'Rourke, superintendent of the mill, has made some minor changes in the past few months, but the mill remains practically the same as designed. Spitzkasten have been added, one below each tube-mill. Each spitzkasten supplies 10 tables with pulp from the tube-mill. At present the mill is handling 200 tons through 24-mesh screen and later on will handle 500 tons per day through 16-mesh screen, the ore being re-ground in the tube-mills. The mill is constructed of steel and concrete throughout and is considered one of the finest mills in the county and is a credit to the manufacturers. It is situated at Animas Forks on the line of the Silverton & Northern Ry. at an altitude of 11,300 ft.—about timber line. The mine is 1,000 ft. higher and the ore is carried to the mill by an aerial tramway, Bleichert type, two miles in length. W. Z. Kinney is general superintendent of the mine and mill.

NEVADA.

CHURCHILL COUNTY.

At the Nevada Wonder, the Brock property, the shaft is 500 ft. deep, and they have started a cross-cut for the vein at that depth. Three veins have been developed in the upper levels, one of them being 50 ft. wide where it was cross-cut.—At the Hidden Treasure the cross-cut on the 160-ft. level has passed through 50 ft. of vein matter and as yet the other wall has not been found.—Last week the Jack Pot made a shipment of 25 tons which is said to average over \$200 per ton.—The shaft on the Dickey V. is still only 100 ft. deep, but the cross-cut on the 100-ft. level is 65 ft. long and has just cut the vein.

ESMERALDA COUNTY.

(Special Correspondence).—The mines are looking better than ever before, and in spite of the car shortages and other troubles, the output is nearly \$400,000 per week. Building operations are in full swing and there are no labor troubles to retard the early completion of several fine stone and brick business blocks.—The richest ore-shoot, considering its size, ever opened in a Goldfield mine is now being mined in the Little Florence lease. This orebody, which was found on the 400 level, is five feet wide and will average \$1,000 per

ton. The ore is principally quartz containing yellow seams of gold, together with black sulphides. The new 500-ft. shaft will be finished in a few days and will greatly facilitate hoisting. At present the ore is brought up through a very inconvenient inclined shaft. The lease runs until Feb. 8, 1908, and has already paid four dividends of \$100,000 each. The 500-ft. shaft is being sunk in record time and will be completed in less than 40 days. Work is being carried on at four different points in the shaft and is under the superintendence of A. H. Warner, a Columbia graduate.—The Consolidated Mines Co. is shipping 10 cars per day, and after the present car shortage this number will be increased. The ore runs from \$50 to \$800 per ton and, with the daily output of about 400 tons, brings the total to over \$1,000,000 per month.

The work is being gradually concentrated at the Mohawk shaft; men are being dismissed at the adjoining Consolidated properties and added to the force in the Mohawk.—An important discovery at a depth of over 300 ft. was made lately on the Victor property, showing a four-

Map of the New Mining Districts of Nevada and California.

foot vein of ore giving assays of over \$60 per ton. This is considered an important find, as it proves that in that locality ore exists at depth and it will extend considerably the area for legitimate prospecting at Goldfield. The Victor was owned by the Goldfield Combination before that company was absorbed by the Consolidated. The rails of the Las Vegas & Tonopah R. R. have been laid as far as Columbia and in a few days will be in Goldfield. Oct. 28 has been selected as 'Railroad Day,' and a mammoth celebration is being planned by the city.

Goldfield, Oct. 16.

NYE COUNTY.

(Special Correspondence).—That the mining camp of Manhattan has taken on renewed life and activity is evinced by the increased traffic to and from the town and by the activity displayed in mining operations throughout the district. Manhattan is not primarily a high-grade camp; she depends upon ores of good milling grade for her future. The absence of mills and the San Francisco disaster were the cause of the deadness that followed the first boom; but now three mills are under course of construction in Manhattan. The Wolf mill will probably be running by Nov. 1; its capacity is 100 tons per day. Within 60 days the Lemmon 10-stamp mill will be in operation, to be soon followed by the 50-ton mill built by Davis & Chapman, which is equipped with Huntington mills.

Under the above condition of affairs the lessees are working with renewed efforts, and are piling on their dumps quantities of rich milling ore, while many of the lessees on the various properties are also taking out shipping ore along with the milling ore.—On the 350-ft. level of the Thanksgiving property the same high-grade ore has been encountered as found on the upper levels. Operations have been suspended for a few days, awaiting the arrival of a station-pump to handle the water.—Messrs. Cole & Burns have secured a lease on the entire surface of the Little Gray claim, and will work the dirt by sluicing. Water will be obtained from the Gold Wedge shaft. Considerable placer mining is being done throughout the Manhattan district. On the Indian Camp claim several sets of lessees are at work, all obtaining good results from dry placering. The surface dirt runs from \$1.00 to \$10.00 per cubic yard. Wilcox & Golish have taken a lease on the company shaft of the Indian Camp, and will develop the veins which have been traced through the company's property.—On the Jumping Jack claim, in addition to the placer diggings, Kendall & Douglass are extracting high-grade ore from the 50-ft. level in their lease. About 12 in. of the vein on which they are working will assay between \$300 and \$400 per ton in gold; considerable good milling ore is also being taken out.—On the Stray Dog Mr. Giffin is mining some high-grade along with the milling ore. Dan McNamara recently secured a lease on the Stray Dog, and was sacking ore within a week from the signing of it. In the early days of the camp the Stray Dog became well known on account of the specimen ore taken out by the lessees.—On the Wolfstone Extension galena has been found in considerable quantity at a depth of 50 ft.; the formation is identical to that of the Thanksgiving and Bryogle. The Wolfstone Extension people believe that they will develop rich ore-shoots similar to those of their neighbor, the Thanksgiving.—No less than half a dozen sets of lessees on Litigation Hill are sacking high-grade ore. Specimen ore is a feature of Litigation Hill, some of the finest specimens ever seen in the State having been taken from this ground, which is a portion of the Dexter Mining Company.

Manhattan, Oct. 15.

(Special Correspondence).—Hydraulic mining has commenced on the ground of the Combination mine by the Round Mountain Hydraulic M. Co. Two giants are in position, and a large area of rich ground is being treated.

—The Round Mountain Combination Co. has commenced active development at its group, which includes the Hobo Fraction, White Horse, and Blue Jay No. 2. An incline shaft will be sunk at a point between the east line of the Sunnyside and the Kinney lease. When a depth of 100 ft. has been reached, driving will be started.—The Solid Gold Co. has struck a four-foot vein of rich ore in the new shaft on the Daisy. The ore assays from \$40 to \$500 per ton, and was struck at a depth of 36 ft. The strike is said to be one of the most important made in the camp.—The Crescent lease on the Daisy is driving for the vein. The shaft is down 125 ft., but the vein has not yet been encountered. A hoist has been erected by the lessees.—Several companies have applied for leases on the Combination ground. The Combination is controlled by the Ish brothers of Goldfield.—Rich ore is being extracted from the shaft at the Antelope, and extensive developments are under way.—Some of the richest ore ever found in the camp is being taken from the shaft of the Sunnyside. Development is opening up a rich body of ore.—The Daisy Co. owns the principal water rights in the district and will supply local mills and power plants.—Round Mountain is enjoying considerable prosperity, and does not seem to be affected by the depression in the stock markets. Close corporations control several of the leading mines in the district. The principal operators are the Round Mountain, Combination, and Daisy.

Round Mountain, Oct. 15.

(Special Correspondence).—The past month has been one of marked activity in the Bullfrog district. The Shoshone mill began operations last week and 150 tons are now being crushed daily, which represents one-third the capacity of the plant. Besides this 1,000 tons were shipped to the Salt

Lake smelter during the month.—The Mayflower management has given out a detailed statement of the showing on the fourth and fifth levels in that mine, and also future development plans. The orebody, which has been cut on each successive level, showed about 20% increase in value on the 400-ft. level, where it has been cross-cut for over 20 ft. without finding the other wall. In driving for the vein on the 500-ft. level, the first water in the mine was met. The flow increased rapidly until at present some 10,000 gal. are being hoisted daily by bucket. A Knowles Duplex station pump has been purchased and will be installed at once. The drift on the 500-ft. level has just entered the vein, showing that the ore, which has heretofore been oxidized, has changed to a sulphide at water-level. Now that the water question has been solved, the 50-ton mill designed by the Traylor Engineering Co. of New York will be erected, in which the ore will be amalgamated, concentrated, and then cyanided.—A recent 23-ton shipment from the National Bank mine gave an average return of \$484 per ton. This mine is among the best milling propositions in the district, an immense amount of ore having been blocked out by the 7,000 ft. of development work that has been done upon the property.—The Phillips-Moesser lease on the Gibraltar is said to be paying well, as the lessees have sacked a number of tons averaging about \$100 per ton.—The 20-stamp mill of the Keane Wonder mine, over near Death Valley, commences operations this week. The mill is at a point considerably below the mine, the ore being conveyed thither by means of an aerial tram; the latter also furnishing power for the 10 by 16-in. Blake crusher.—The Gold Bar mill is in course of construction. Work at the mine has been suspended until the mill is finished; large quantities of ore are already blocked out. There is considerable talk in regard to building a custom mill at Rhyolite. One is badly needed and would undoubtedly prove a paying proposition, as there are a number of mines close to the town of Rhyolite which, although they have considerable ore, have not felt justified in commencing milling operations individually, principally because of a lack of water supply.

Rhyolite, Oct. 17.

WHITE PINE COUNTY.

The diamond-drill hole started from the 100-ft. level of the McDonald-Ely is down about 100 ft. The 400-ft. level is showing some improvement.—The old Cumberland group at Osceola will soon begin to send ore to the 5-stamp mill. The Lead King Co. has shipped a carload of ore carrying 70% lead. This was taken from a drift on the 50-ft. level.

OREGON.

JOSEPHINE COUNTY.

(Special Correspondence).—At present the Galice Creek district, in the western part of Josephine county, Oregon, is attracting considerable attention. For many years this district was famed for large placer mining operations; its hydraulic mines are still producing much gold. But recently large, and in some cases high-grade veins of quartz, have been discovered and are being developed. Until about a year ago, except in a few isolated cases, no attempt had been made to open up the extensive veins known to exist; the 'pocket hunters,' who roam the hills in search of surface bonanzas, would not 'waste' time on low-grade veins. One of the exceptions was the well-known Sugar Pine mine, which has produced considerable high-grade ore, but which is now closed because of the quantity of water found in the lower levels. Two well defined mineral belts cross the district in a general north and south direction. On the eastern border lies the Big Yank, a lode, or rather a mineral zone approximately 300 ft. wide that can be traced nearly 12 miles. The ore-shoots in it now developed carry gold, silver, and copper. The Alameda mine, on this belt, is now shipping copper ore to the Tacoma smelter for treatment and the company contemplates the early erection of a smelting plant to handle the output of their mine. On the western border of the district lies the Chieftain belt, which passes south into California. At the Strenuous Teddy mine the West Fork of Galice creek has cut this great belt to a depth of 2,500 ft. Here this mineral zone has a total width of nearly 900 ft. with porphyry on its hanging wall

and serpentine on its foot-wall. In this width are several veins of ribbon-quartz, sulphide, and telluride from 2 to 44 ft. wide. Recently C. H. Smith, of Gold Hill, took samples from 12 veins on the Strenuous Teddy; these samples gave returns ranging from \$2.65 to \$328 per ton. This mine, which was discovered last year, is now owned by James B. Nesbit of Galice, C. H. Farmer of Gold Hill, Josephus Kester of Jackson county, and E. C. Clanton of Grants Pass. The three gentlemen first named also own a number of adjoining claims, covering the outcrop of the Chieftain belt in that vicinity. This belt both to the north and the south has been generally staked because of the reputation that the Strenuous Teddy mine is giving it.—A blanket vein, which leaves the Chieftain belt where the latter crosses Galice creek, can be followed in an easterly direction for a mile. In places this vein has a width of 16 ft. and carries good values in gold; considerable development has been done on it at the Gold Plated mine.—The three miles of country rock between the Big Yank and the Chieftain belts is more or less intersected with veins, some of which are producing shipping ore. Among these are the Golden Wedge, the Sanders, and the Oriole mines, at which a large amount of work has been done during the past year. The Black Bear mine, owned by the Green Bros., and the Robertson group of free-gold properties on Rich Gulch, also have good orebodies opened up. An extension of the Oriole, now under bond to Mr. Doan of Los Angeles, is being developed and a vein of high-grade ore has recently been struck. Between the west and south forks of Galice creek the Cold Spring group, owned by John Reeves and now under bond to the Alameda company, is being developed. A wide vein carrying gold and copper has recently been discovered in this group.—Most of the gold-bearing ores of the Galice district are base, but some free-milling ore extends to considerable depth. In the Strenuous Teddy, Oriole, and Sugar Pine mines the richest ores are tellurides; calaverite and petzite occur in the Strenuous Teddy and sylvanite in the other two. Tungsten, molybdenum, and the platinum group of metals are also found in the district.

Gold Hill, Oct. 11.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The old rumor in regard to the building of a smelter, in which the Republic ore would be fluxed with the lead ore from the Cœur d'Alene, has again been revived.—Considerable ore has been shipped from the Pierre lake and the Orient districts in Stevens county during September. Work on the California mine, 10 miles southeast of Republic, was suspended about two years ago on account of the necessity of a new shaft and disagreement among the stockholders. The California group of claims is an extensive property, but no attempt has ever been made to develop more than the one pay-shoot, although there are several veins. The California mine has produced about \$100,000. Some Chicago people have bonded the property and have begun to reopen the mine. The ore formerly extracted contained gold, silver, copper, and lead and was the richest ever shipped out of the district, excepting that shipped from the Republic mine in the early days of the camp, which netted at the smelters over \$300 per ton. The annual stockholders' meeting of the company was held here a few days ago, when the old board of directors was re-elected.—J. C. Beidelman, metallurgist for The Amalgamated Republic Mines Co., has examined the Quilp, Pearl Consolidated, Trade Dollar, Ben Hur, North San Poil, Mountain Lion, Little Cove, and Black Tail mines and reports having seen more ore than he had expected. His company has acquired options on the first five named mines and the Republic also. He said that although he is fully confident of the success of his method, which follows with few modifications the accepted cyanide practice, he will not consent to begin with an experimental mill of over 50 tons daily capacity, which could be gradually added to when found adapted to the ores of the camp. Mr. Beidelman has left for New York and expects to return here after consulting with people in that city. If the mining companies interested in Republic camp will agree to his

Special Correspondence.

Butte, Montana.

The Heinze Failure.—Butte & London.—Pittsburgh & Montana.—The Barnes-King Fiasco.—A Salted Placer Mine.—Revival in the Homestake District.

The suspension of the State Savings bank in Butte, following the sensational slump in Davis Daly and United Copper stocks, gave a rather severe series of 'bumps' to the local followers of F. Augustus Heinze. Mr. Heinze owns 62% of the stock of the State Savings bank, and the suspension of the firm of Otto Heinze & Co. at New York precipitated the suspension of the State Savings bank, although, it is claimed, there was no connection between the two. The bank officials feared that the Heinze name associated with a failure would result in a run on the bank and the doors were closed. Not more than 20 depositors out of more than 6,000 were at the bank to withdraw their deposits. The bank carries more than \$3,000,000 in savings deposits, and the officials claim the bank is solvent. The State Examiner is in charge of the institution.

The Butte & London Co. has begun cross-cutting north and south from the 1,100-ft. station and expects to cut at least one vein within a month. H. V. Winchell, consulting engineer for the company, advised a change in the plans, which were to sink to a depth of 1,500 ft. before cross-cutting. Mr. Winchell is also consulting engineer for the Pittsburgh & Montana Co. and he has found that the richest orebodies in the mines of that company are on the 800-ft. level east of the cross-cut connecting the two Pittsmtont shafts. These orebodies lie southeast of the Butte & London shaft, and Mr. Winchell gave it as his opinion that the Butte & London is as likely to find ore at the depth of 1,100 ft. as at 1,500. The 15-ft. vein cut by the Boston & Montana in the Greenleaf shaft at a depth of 840 ft. strikes through Butte & London ground just south of the shaft and this vein is likely to be cut within a month. In the Greenleaf the vein carries good commercial ore. The Boston & Montana Co. will also cross-cut to the vein at a depth of 1,000 ft., the present depth of the Greenleaf shaft. The Butte & London will extend its cross-cuts through the greater portion of its extensive territory.

The Pittsburgh & Montana Co. expects to resume operations during the coming week. Mining has been suspended for more than a month because of the curtailment policy of the Amalgamated, which had purchased the ore of the Pittsburgh & Montana. The latter owns an experimental smelter, which was built by Ralph Bag-galey, former manager for the company, and this is being remodeled and fitted up as a modern smelter; when completed, it will be able to treat about 200 tons of ore per day. Before the shut-down the company was producing at the rate of about \$2,000,000 per annum.

E. E. Chase, of Denver, has been engaged during the past week in making an examination of the Barnes-King mines for Boston stockholders. The announcement by the New York men who floated the company that they, too, will have another examination made, does not arouse much hope or interest among stockholders in Montana, as it is remembered that the original reports on the property were made for this firm and for the purposes of flotation, through which, according to the reports of the present officials of the company, the stockholders have been swindled out of nearly \$2,000,000. Reno Sales, a geologist for the Amalgamated, has also been employed by the Barnes-King officials to make a geological exami-

nation. The new officials of the company have not yet been able to get from the former directors or promoters the original reports on the property nor a statement of accounts showing what became of the \$2,000,000 subscribed, though demands for them were made several weeks ago. The first president of the company, John C. Lalor, who is supposed to have had possession of some of the papers, has gone to Europe. Reports from disinterested persons in Fergus county now confirm the reports made by Messrs. Gillie and Goodale that there is very little ore in the mines. Senator Henry M. Rae, who is operating in the same district and is familiar with the Barnes-King mines, says that there is no doubt that the Gillie-Goodale report is correct and that there is not more than \$50,000 worth of ore in sight. However, he adds that there never was in the history of the mines any large amount of ore blocked out at any time. The ore lies in bunches and detached bodies, and new orebodies were repeatedly found, which, he believes, will be the case for a long time to come. There is an immense area of virgin ground to be prospected and there is always a possibility of encountering a rich orebody. It is growing more apparent as facts are investigated that the former directorate made a studied effort to deceive the public, and up to the time the property had been examined by Mr. Gillie lying reports were sent from the mine, even to the extent of misquoting Mr. Gillie. The ore actually in sight and blocked out was represented at different times by different reports from 5,000,000 down to 400,000 tons. Mr. Gillie found not more than 25,000 tons.

To a less extent, but in a more sensational manner than in the Barnes-King affair, another lot of Montana and Washington men have been swindled, with a loss of about \$300,000, through 'salted' placer mines in Wyoming. The Greenoughs are the principal losers. The property is known as the Red Canyon placer, and was taken over by the Greenoughs and associates for \$1,500,000 after exhaustive examinations and tests had been made, under the guidance of the men who are now suspected of having salted the ground. The reports were so good that the purchasers prepared to spend \$500,000 to bring a river through a mountain tunnel in order to get sufficient water to work the ground on a large scale. Chicago men offered the Greenoughs \$2,500,000 for the property and the offer was refused. E. W. King, one of the chief owners of the shell that was sold to the Barnes-King Co. for \$2,000,000 was offered an opportunity to take an interest in the Wyoming placer proposition, but his experience caused him to be wary and he became suspicious of the glowing reports, so he determined to make a personal examination. The result was that barely traces of gold were found where previous examiners found rich gravel. He reported to the Greenoughs and they then made another examination with the same results as King. It is estimated that no less than \$50,000 worth of gold was used in 'salting' the ground.

Activity in mining is being revived in the old Homestake district a short distance east of Butte on the line of the Northern Pacific railway. Years ago a number of gold properties were worked there, but none of them were ever extensively developed. The first returns were in many cases sensational, but the ore did not continue to any great depth. A number of Butte men have secured a bond and lease on a group of claims, including the Last Chance, Hillside, Gray Copper, Nickel Plate, and Mammoth. The life of the bond is 18 months and the price to be paid is \$50,000. Former operators did a lot of development work and uncovered a good showing on the Last Chance, but they lost the property by allowing the bond to lapse through a mistake. They are now threatening the owners and the new operators with liti-

gation. When they lost the property they had some good copper, silver, and gold-bearing ore.

Mexico City.

News From Guanajuato.—The River Scheme.—George Bryant's New Enterprise.—The Belt Railroad.—Sale of the Humboldt.—Activity at La Luz.

Since writing the letter which appeared in the MINING AND SCIENTIFIC PRESS of October 12, wherein I stated that George W. Bryant "has never been able to interest sufficient capital in his dredge scheme in the Guanajuato river to carry it through, and the enterprise has now been indefinitely laid aside." I have found that I was largely mistaken and that E. G. Spilsbury, who was one of the first that Mr. Bryant was able to interest in the river scheme, has for some time been engaged in washing the deposits in the Guanajuato river bed that have

estimated length of road of 79½ km., or about 50 miles; the location survey was to begin in three months, the first 10 km. completed in 15 months, and then 10 additional each year, with the entire road finished at the end of five years. Certain links in the line, between the company's own properties, have been completed, and September 15 of this year was celebrated by breaking ground on the main line, which was to be followed by a rapid completion of the whole, but now it is rumored that the general stringency in the money market will lead to a temporary cessation or curtailment of operations; it is to be hoped, however, that if such is true, it may not be for long, as this road will give transportation to many out-of-the-way properties and, next to the success of the cyanide process on Guanajuato ores, should prove the greatest impetus to the camp in recent years. In addition to the large properties of the Guanajuato Consolidated Mining & Milling Co., the Guanajuato

Map of Mexico.

been accumulating for centuries and that the returns have been far in advance of what was expected. The latest of Mr. Bryant's more important promotions is the Mexico Milling & Transportation Co., organized under the laws of New Jersey, with \$7,000,000 capital, of which \$2,000,000 were 6% preferred and \$5,000,000 common. The officers are George W. Bryant, president and general manager, J. J. Welch, vice-president, E. A. Wiltsee, consulting engineer, and F. G. Peck, treasurer, the stock having been placed by the Securities Corporation Co., Ltd., of 40 Wall St., New York. This company is controlled by the Guanajuato Development Co., which latter also owns the Pinguico mine, and has as its principal object, in addition to its two custom mills in successful operation in Guanajuato, the building of a standard-gauge belt-line to connect all the principal mines of Guanajuato district with the Mexican Central line at the station of Tepetate. The concession for this belt-line was obtained in August last authorizing the construction and exploitation of a railroad from Tepetate to Santa Rosa, for 99 years, touching at various mines, mills, etc., with a branch to La Luz and other camps, making a total

Reduction & Mines Co., and the Guanajuato Development Co., those of the Guanajuato Amalgamated Gold Mines Co. are proving to be valuable holdings and in addition to the ore from their mines a considerable tonnage from the old dumps is to be treated. El Cubo Mining & Milling Co. continues to be a steady producer. Next to the Pinguico, two shafts are being put down on the Humboldt, which was sold by Chas. Morse and E. J. Kimball to P. J. Nolan and associates for \$150,000, and though thought to be a pretty high price for a prospect, it was figured that the Carmen-Pinguico vein, which had been proved so rich, must enter the Humboldt on its strike as well as several other minor veins which seem to join the former on its way to the Humboldt, so that the property has every prospect of proving valuable. The Aparceida, next to the Sirena, is being developed by George W. Bryant, and he and others have taken over the La Luz and Bolanitos in the La Luz district, and it is said a \$2,000,000 company will be organized for their development and the erection of a large mill, as the past record of the properties assures profitable operations. The American Mining & Milling Co. has its

15 stamps and cyanide mill in operation and is treating 45 tons per day from its Siglo 20 and Inglesa mine. The Santa Maria and San Nicolas del Monte are taking a new lease on life, and the Edward VII gives promise of a bright future. On the Cabrastante, Dwight Furness, who has allowed the property to remain idle for some years, has interested Chicago people. The mine is being unwatered and is said to have some six feet of good ore in the main winze about 280 ft. below the tunnel-level. A cyanide mill will probably soon be needed. The Providencia Mining & Milling Co., at Tajo de Dolores, is putting in a complete electric equipment, which, with the new 60-stamp mill ordered, will call for about 600 horsepower.

Salt Lake, Utah.

Heinze's Affairs and the Ohio Copper Co.—Curtailment of Copper Production.—Shipment From Tintic.

The collapse of the United Copper 'corner' on Wall Street and the apparent financial distress into which F. Augustus Heinze and some of his associates have fallen, has had its effect here in Salt Lake. It is not serious as yet, however, and it may be that the Heinze Utah enterprises will pull through without any hard knocks. Mr. Heinze is a controlling factor in the Ohio Copper Co. at Bingham, which has been carrying on a vigorous campaign of development during the present year and which has a new concentrating mill with a capacity for the treatment of 2,000 tons of ore daily nearing completion. The stock sold as low as \$2 per share during the week as a result of the disquieting news about Heinze's finances. This was followed by other reports to the effect that the Ohio company is not as well supplied with funds as many had been led to suppose and that unless Mr. Heinze managed to get out of his entanglements, the Ohio company might become temporarily embarrassed in carrying its plans into execution. Mr. Heinze has regarded the Ohio Copper mine as being one of the most valuable propositions at Bingham and his engineers, many months ago, mapped out a plan of development along broad lines. This included the extension of the Mascott tunnel of the Dalton & Lark mine into the property of the Ohio company and equipping it in a manner which, it is claimed, will enable the production of copper at not to exceed 6 cents per pound. The equipment of the Ohio was to be followed up by the erection of a large smelting plant on the south shore of the Great Salt lake and the Miners' Smelting Co. was organized to carry out the project; some railroad construction was planned and it was Mr. Heinze's intention to become—within the next two years—a formidable competitor of the existing smelting concerns now operating in the West.

The curtailment of production still goes on and the ore output of the mines will probably continue considerably below normal until the metal market shows improvement. The Bingham Consolidated has closed its Dalton & Lark mine at Bingham as far as the mining of ore is concerned, but will keep a small force on development; the Ohio Copper Co. has cut every possible corner, but is still pushing development; the Boston Consolidated has curtailed materially; the Last Chance mine of the Nevada Utah Mines & Smelter Co. has let out all but 15 men and a number of other mines have adopted the same policy. The Utah Consolidated, Utah Apex, Utah Development, and Utah Copper, however, continue production about as usual.—At the annual meeting of the Tintic Mine Owners' Association it developed that the mines of the Tintic district paid out \$260,000 more in wages in the last fiscal year than during the previous one. The old officers of the organization have been

elected. Clarence E. Allen, mines manager for the United States Smelting, Refining & Mining Co., is president.—The Prince Consolidated Mining & Smelting Co. has been organized in Salt Lake to operate in the Pioche (Nevada) district. It has absorbed the properties of the Phoenix Reduction Co., consisting of the Prince mine, a large tailing dump at Bullionville, mill and smelter sites, the entire area covered being about 1,000 acres. The company has been financed by the interests identified with the Ohio Kentucky company at Pioche.

The ore and bullion settlements reported through Salt Lake banks last week amounted to \$672,000.—The shortage of labor on the Western Pacific railroad, now building from Salt Lake to San Francisco, is reported to be materially relieved. The release of so many men in the mining camps during the past few weeks is supplying the demand.

Ore shipments from the Tintic, Utah, district last week amounted to 132 carloads, the contributing mines

Utah.

and amounts being: Ajax, 2; Beck Tunnel, 7; Black Jack Con., 2; Carisa, 3; Colorado, 9; Centennial Eureka, 42; Eagle & Blue Bell, 6; Eureka Hill, 2; Grand Central, 8; Lower Mammoth, 10; May Day, 5; Mammoth, 5; Scranton, 8; Tintic Iron, 9; Uncle Sam, 5; Victoria, 3; Yankee Con., 6 carloads. The milling plant belonging to the Mammoth Mining Co., at Tintic, is being dismantled. The low-grade ores of the mine will likely go to the Tintic Smelter Co.'s smelter for treatment in the future. The Mammoth company is shipping some high-grade gold ore to the Salt Lake valley smelters. The directors have posted a dividend of \$20,000. The Tetro mine has been closed temporarily on account of the lack of funds to continue development. The alterations being made in the May Day mill are about finished. The plant has been enlarged to treat 65 tons of ore daily.

The annual meeting of shareholders of the Honerine Mining Co. will be held during the next week at which time the matter of devising ways and means of paying off the indebtedness of about \$200,000 will be considered. The Honerine mine and mill is at Stockton. The installation of new equipment in the mill of the New Stockton Mining Co. is in progress.

Cripple Creek, Colorado.

Treatment Charges.—Lowering of Rates.—Important Reduction.—

El Paso Co. to Lease.—Strike in the Sacramento, Deerhorn, Little Queen, and Old Gold.—Successful Leases.

A move of greatest importance is a concession by the U. S. R. & R. Co. in the lowering of treatment charges on Cripple Creek ores; the schedule going into effect on the 15th inst. Many properties have been compelled to close down in the last two months owing to the prohibitive rates charged by the smelting companies on low-grade ores, and the destruction of the Golden Cycle mill at Colorado City; under the new schedule, however, many mines have signified their intention of resuming, although the rate still does not equal the low charge made by the Cycle management, but it is hoped that by largely increasing the tonnage still better rates may be obtained. It will be seen by a comparison of old and new rates that ore under two ounces is particularly favored. The difference on half ounce to ounce ore is representative of the margin between profit and loss with regard to this class of Cripple Creek ores, so that a large amount of low-grade stuff will be affected by the change. The elimination of the sulphur penalty, which is a part of the concession, and always a thorn in the side of the shippers, will have much bearing on the general output; it was looked upon as extremely extortionate. Following is a comparison of the new and old rates:

Ounces of gold per ton.	New Rate.	Old Rate.
1/2.....	\$ 5.25	\$ 6.25
3/4.....	5.75	7.50
1.....	6.50	8.00
1 1/4.....	7.25	9.00
1 1/2.....	7.50	9.25
2.....	8.50	10.25
3 (eliminated).....		11.00
5.....	9.50	11.50
7 1/2.....	12.00	13.00
10.....	14.00	15.00

It is reported that the El Paso Co.'s property on Beacon hill is to operate under the leasing system; the upper workings from the 600-ft. level are being surveyed into blocks. Fair royalties, it is said, will be granted. The mine below the 600-ft. level is under water, draining of which depends on the tapping of the watercourse by the deep drainage adit. It is expected that about 150 men will be employed.—The Sacramento claim of the Stratton estate on Bull hill is reported to have a rich strike, the ore-shoot at a depth of 300 ft. contains a streak six inches wide showing rusty gold; assays give returns as high as \$9 per pound. The Sacramento has had many rich pockets in the past. Charles Outcault, Jack McNeely, and Otto Carrol of Goldfield (Colo.) are the lessees who made the discovery.—The famous Deerhorn mine of the Stratton estate on Globe hill is reported to have a rich strike; after much exploring for the original vein, which had faulted, the ore-shoot has been broken into, the ore appearing in kidney form with assays ranging from one to eight ounces per ton. William E. Fitts and Ollie Keener are the lucky lessees.

Blanchard & Eaton operating in the Little Queen mine on Gold hill have a new discovery that is very promising; an ore-shoot has been encountered at the junction of two veins, assays giving returns of \$50 per ton. The find is 200 ft. from the portal of the Good Will adit, and was discovered by means of a raise from the level of the tunnel 480 ft. below the surface.—The superstructure of the Stratton's Independence mill is rapidly looming into shape; the foundations of all the various buildings are completed and another month will see everything under cover. Machinery is arriving every day and so far no delay has been experienced in the construction, weather

as well as prompt arrival of material helping to make a record in building operations.—The Blue Flag cyanide plant on Bull hill is in operation; the full capacity of the mill is 75 tons per day.—The larger of the Homestake mills has just made a clean-up after a 15 days trial run, which was very satisfactory; the experiment of mixing the ores proving successful. As soon as the crushing department is overhauled the plant will be in the field for custom ores. Chief chemist Riebling is in charge.

A great deal of money is being expended this year on properties about Trail Mtn., much low-grade ore is known to exist in this area, and Hillman brothers, of the New & Half Moon group, are reported as having an important body of ore assaying from \$5 to \$30 in gold. They contemplate the erection of a cyanide plant. The Northwestern Iowa Co. on the south slope are treating similar ore at a profit.—The recent strike in the Chicken Hawk mine is proving to be of good size and assays of 1 to 3 oz. are obtained; the 500-ft. level making the best showing.—Humphreys & Thompson sent out five carloads from the Little Clara property; three cars, containing the better grade ore, comes from the famous Little Clara flat vein, where much ore is blocked out.

Toronto, Canada.

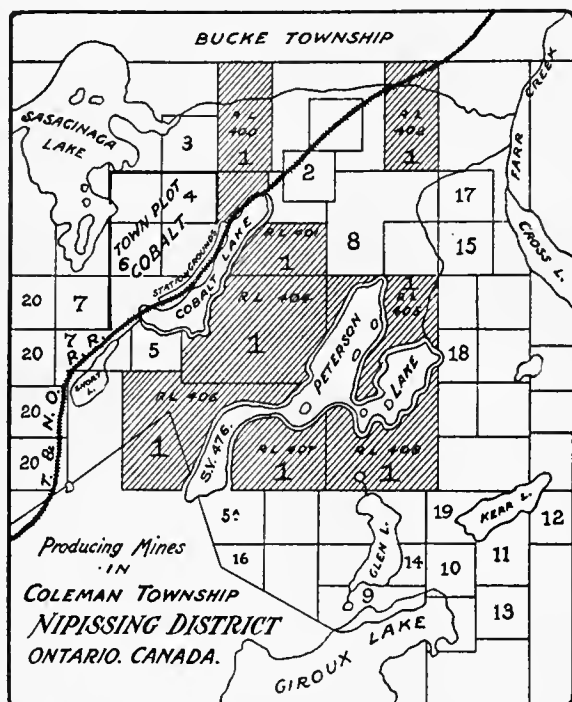

Iron Smelter at Toronto.—Shipments From Cobalt.—Recent Discoveries.—New Concentrator.—Government Receipts From Successful Mining.

An important proposition looking to the establishment in Toronto of an iron smelter for the treatment of the ore of the Moose Mtn. iron mines north of Sudbury, which are now being developed, is under consideration by the city authorities. D. D. Mann, of the firm of Mackenzie, Mann & Co., who are largely interested in the Moose Mountain, Ltd., the company formed to work the mines, has submitted a proposal under which the company agrees to erect a smelter with a daily capacity of 1,400 tons of ore to be followed by the establishment of subsidiary industries, such as rolling mills, steel plants, car works, etc., provided the city will grant them 350 acres of marsh land in Ashbridge's bay in the eastern part of the city. The land at present is mostly covered with water. The company undertakes to reclaim it if the grant is made. The citizens are generally favorable to the acceptance of the terms, but the matter is in abeyance until the City Engineer furnishes a report. The company is mainly composed of American capitalists, John W. Gates, of New York, being the president, and is capitalized at \$2,500,000, which is all paid up.

The appeal of the Dominion Coal Co. from the decision of the judge holding them liable for heavy damages in the action brought against them by the Dominion Steel & Iron Co. will be heard by the Appeal Court of Nova Scotia, which meets Nov. 9. It is unlikely, however, that the case will be reached before December. Both parties appear determined on a fight to a finish, which will probably result in the case eventually going to the Imperial Privy Council.

Cobalt ore shipments for the week ending Oct. 12 were 197 tons from the following mines: Buffalo, 30 tons; La Rose, 43; McKinley-Darragh, 72; Nipissing, 30; and Townsite, 21 tons.—The last car of ore shipped by the Foster mine netted \$36,119. On this property a vein of smaltite 6 to 10 in. wide has been found on the 75-ft. level at the junction of No. 5 and No. 8 veins.—The Airgoid mine is reported to have been sold to the owners of the Nova Scotia, which it adjoins. The men employed at the Airgoid have been laid off.—The Silver Bar mine has recently been taken over by Michigan capitalists and work, which had been suspended for some time,

resumed. In driving at the 150-ft. level a rich vein was encountered.—At the Nancy Helen the main shaft is down 123 ft. and will be put down to the 200-ft. level. Two drifts have been started at the 100-ft. level, one southeast on the main vein, which shows an average width of 8 in. of rich ore, with thick native and wire silver on one side of the vein.—J. M. Elmer, manager of the Cobalt Central, reports the concentrating plant ready for operation and states that there are 1,800 tons of ore awaiting treatment which it is expected will average about \$200 per ton. Additional ore to the value of about \$750,000 is blocked out in the Big Pete mine.—A rich 6-in. vein has been struck at the Tretheway mine at the 50-ft. level and about 15 ft. from the new shaft.—The

new vein of the Hudson Bay has been stripped to a considerable distance and shows up better than on the surface. An assay taken of ore from the niccolite end of the vein showed \$80 in silver per ton. The vein is about 300 ft. from the main shaft and a cross-cut at the second level will be extended northward so that the vein can be worked from the main shaft. The company is erecting sleeping and dining camps to accommodate 80 men.—At the Bailey Cobalt a 15-in. vein of decomposed calcite, cobalt, and silver has been found near No. 2 adit on the hilltop. A shaft will be put down on the vein. In driving from No. 1 adit about 100 ft. three other veins have been found, all carrying native silver.—Operations have been resumed at the Little Nipissing mine and a vein struck of several inches width carrying cobalt and smaltite and showing native silver.

J. H. Black, managing director of the Strathcona Silver Mining Co., with the president, R. T. Mullin, and a party of Montreal stockholders, visited Cobalt this week. The Ontario Government has received from the O'Brien mine owners a check for \$50,992, being the amount of royalties on the output for the three months ending Sept. 30, on the basis of 25% on the value of the ore extracted. The total amount so far received, including this last payment, is \$222,945.

Denver, Colorado.

Machinery for New Zealand.—The Supply of Coal.—Railroad Greed.—Local Politics.—News From Cripple Creek.

Denver is felicitating itself on an order for a smelting plant from New Zealand, which a local company is engaged in filling. The order is not a large one, but it is looked on as the forerunner of more important ones if the plant should prove successful. The equipment is for a 150-ton hot-blast pyrite smelter, and that Denver should be chosen to furnish the machinery for a country so far distant as New Zealand is naturally a source of some pride to her citizens.

One of the burning questions in the Rocky Mountain States is the supply and cost of fuel. These States possess ample fuel resources, the larger part of which are as yet little developed. It would seem that in localities where in many places the ranchman can dig his coal on his own land, the question of fuel ought to be one of the smallest importance. Quite the contrary is the case, however. The production of coal is either monopolized by the railroad through their coal-mining branches, or else by corporations that through their affiliations with the railroads are able to control the situation. In one instance a semi-bituminous coal, mined at a point directly on the main line of a railroad, is sold at an important town on the same line and less than 50 miles away at \$6.25 per ton. In another, a lignite mined within two miles of an important city is sold there at \$3.75 per ton. When we consider how many hundred per cent on the cost of mining this is, the suspicion naturally arises that there is a nigger in the wood-pile somewhere. One of the daily papers of Denver is making a practical application of its strenuous advocacy of reasonable rates by going into the coal business itself, and selling fuel for household purposes at a reasonable rate. Such efforts are rarely rewarded with the success they deserve; there is too much opportunity for the railroad and mining companies to block the operations of anyone who is not in friendly relations with them. The attitude of the railroads in the economic development of the West has greatly changed in the last few decades. The railroads came in the guise of a philanthropic friend, aided by Federal grants and hailed with local enthusiasm, they pushed their way westward to bring the transportation facilities that were the only factor necessary for industrial development. In later years the philanthropic friend appears more like an Old Man of the Sea. Between excessive rates and unequal rates the shipper who is not large enough to enjoy special privileges has a hard time of it. Federal regulation of the railroads is likely to be a popular issue in the West in the next presidential campaign.

Local politics, beyond the squabble over the Soldiers' Home, is largely devoid of present interest. The next senatorial candidate is a subject for desultory gossip. The talk of Thos. F. Walsh seems to have subsided, although his entertaining of Secretary Taft on the occasion of his recent visit to Denver is probably much more to the point than a great deal of talk. His friends are boosting Representative Brooks, of Colorado Springs.

The new mill to treat the dump of Stratton's Independence is rapidly being constructed. Part of the foundation is already completed and it is hoped to have the entire construction finished by the first of the year, but that is doubtful. The expectation is to treat the million tons of dump material at a profit of a dollar per ton, and after it is exhausted there are large quantities of similar material as yet untouched in the mine workings. The Roosevelt deep drainage adit is at last making satisfactory progress. The rate of advance is now somewhat over 200 ft. per

month. The sinking of the intermediate shaft is progressing, and will be considerably expedited by further supplies of machinery, which arrived last week. Between the properties that have suspended operations until they can resume their contracts with the Golden Cycle mill and those that are crippled by the water problem, a considerable percentage of the mines of the area are simply marking time at present.

Nogales, Arizona.

The Patagonia Mountains. — New Railroad to Cananea. — Tube-Mills in the Black Mountain District. — News From Nacozari. — A New Smelter. — The Tabotacachi District.

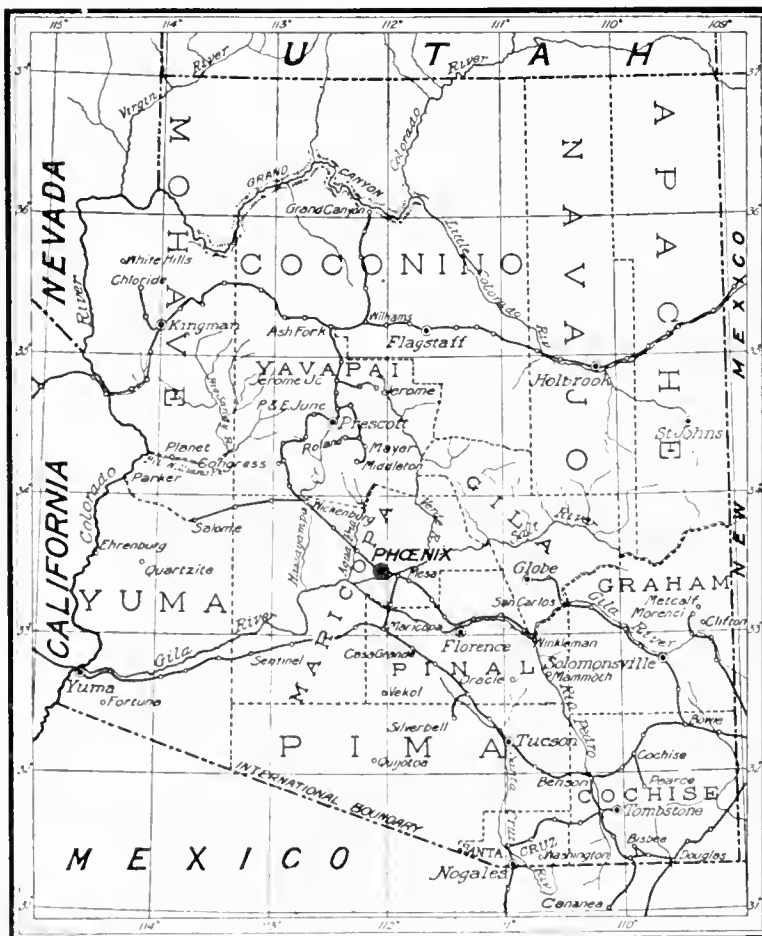

Brown & Wilson, who bonded the Morning Glory mine, situated in the Patagonia mountains, Harshaw district, have been shipping from 8 to 10 carloads of ore per month, and have recently struck higher grade sulphides in the lowest workings. The ore consists of a heavy pyrite, carrying copper, gold, and silver. — The properties being operated by the Duquesne Co. are merely undergoing development, although there has recently been made a mill-run from the Pride of the West. It is stated that the mill is now shut down. The ore consists of zinc-blende, copper as chalcopryite associated with garnet; so far attempts at concentration have been rather unsatisfactory, but it is said that recent experiments with the Elmore process point to a successful solution of the problem. Previously magnetic concentration combined with wet (Wilfley) tables was used. West of Patagonia the Mansfield Copper Co. is vigorously developing and has two shafts down some 300 and 450 ft., respectively, and they are reported to be blocking out a fair grade of shipping ore.

The main topic of conversation at this time is the commencement of grading for the railroad between Nogales and Cananea; men and animals are on the ground, and a warehouse is about completed just south of town. Railroad officials expect the line to be in operation in from 8 to 10 months, but the contractors are allowing 18 months; it is, however, the general opinion that the temporary closing down of the Chivatero property and other mines in Cananea (which will involve the laying off of from 1,500 to 3,000 men) will materially assist the contractors, who will have at their immediate disposal a large proportion of these men. The construction of this road is undoubtedly going to help the city of Nogales, incidentally during the construction period, but later by the large amount of freight passing through, to and from Sonora's premier copper camp, and the intermingling of the people from both cities.

Within the past two weeks several tube-mills have passed through Nogales, destined for the Black Mountain Mining Co., near Magdalena, where the company (which already has 120 stamps installed) hopes to double its production by first crushing to 20 mesh and then re-grinding in the flint-mills. — The Llano Mining & Milling Co., at Llano, Sonora, is again running the cyanide plant on old tailing, and anticipates a nice monthly clean-up. H. Gordon Glore, of Nogales, is consulting metallurgist. — The Campana mine, in the northwest portion of the Altar

district, is running its 10-stamp mill and cyanide plant, and recently made a very satisfactory clean-up, which the manager, E. E. Pope, of Parkersburg, W. Va., believes will be improved during the present and succeeding months. — The numerous copper companies operating in the Sierra Caracahui, to the east of Llano, are quite active installing machinery, and some important strikes are reported.

From Nacozari comes the news that the Lucky Tiger group of mines in the vicinity of the El Tigre was sold to Louis N. Rohn and associates of Denver by Tim S. Lamberson of Douglas. The reported purchase price was \$50,000. Lack of transportation facilities at the El Tigre is retarding development. The stopes and bins are blocked with ore. One car of ore from the Monte Cristo mine of Carlos Soto near Moctezuma showed smelter

Map of Arizona.

receipts of \$10,400, with two more in transit that the assays indicate to be worth \$50,000. The smelter machinery for the Promontorio y Anexas is in transit from Nacozari to the site below Moctezuma.

With the advent of E. A. MacFarland, chief engineer, construction work on the C. R. Y. & P. R. R. is being resumed. The grade has been opened up to Cumpas, a distance of about 35 miles south of Nacozari. Work on the new 1,200-ton concentrator of the Moctezuma Copper Co. is progressing favorably. The structural steel is now being placed and a portion of the mill-machinery is on the ground. The Los Angeles mine of the Arizona Mining & Trading Co. is now installing a crusher and jigs to treat the second-class ore taken out in development work. The ore is mainly chalcopryite. The San Jose mine near Nacozari has resumed operations and is installing a cyanide plant. Development is being pushed at the Rosario, Credo Liberal, Antigua, and Douma properties in the Tabotacachi district and reports speak of considerable bodies of concentrating ore being opened up.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

GRINGO literally means gibberish, that is, language that is unintelligible. It is Spanish, not Mexican, and is employed as a nickname for foreigners.

IN WINTER, in Mexico, the *patio* process requires 20% more time for the completion of the chemical reactions involved, by reason of the lower temperature of the air.

THE average cost of mining and milling a ton of ore on the Rand is \$5.15. The following is a classification of 63 out of the 66 mines which produced gold during last July: Companies working for under \$4, 1; for \$4 to \$4.25, 2; for \$4.25 to \$4.50, 3; for \$4.50 to \$4.75, 8; for \$4.75 to \$5, 7; for \$5 to \$5.25, 11; for \$5.25 to \$5.50, 6; for \$5.50 to \$5.75, 7; for \$5.75 to \$6, 6; for \$6 to \$6.25, 2; for \$6.25 to \$6.50, 3; for \$6.50 to \$7.50, 5; for over \$7.50, 2.

COPPER MINES have always been fairly low-grade, comparatively speaking. Consequently it has been at copper mines that most of the mechanical improvements in mining machinery have been made. Copper mining is credited with the first successful use of steam-engines, iron skips and cages, iron and steel cables, high explosives, and air-driven rock-drills. Savery's first steam-engine was erected at a Cornish copper mine about 200 years ago. The next improvement in steam-engines, Newcomen's engine, was also erected at a Cornish copper mine, and Watt's first engine was for pumping water at Chaeewater, Cornwall.

RATS are the cheapest mine scavengers there are; they are plentiful in the stopes of Bisbee and of the Comstock. The writer knows of no harm that they do underground and, considering the great amount of good that they do, he would even advise their introduction in mines where the men eat underground. Rats are good indicators of impending caves in the stopes. When the rats leave a stope (unless it is due to some obvious cause such as the introduction into a stope of air-drills where formerly hand-drilling was used) it is time for the miners to leave also. The rats sometimes bother candles and, it is said by some, also dynamite, but this damage does not amount to much. In fact the writer never knew of the rats bothering the candles or the dynamite at Bisbee where the rats have plenty of chance to do so; probably they eat the candles only when very hungry. The Malthusian principle prevents an over-abundance of rats at a mine.

At the Waihi mine, New Zealand, the thickened slime from the tube-mills is filtered in two modified Moore filters. The 'basket' consists of 9 or 11 frames, made of closely corrugated iron; these corrugated plates fit into the encircling vacuum pipes which are cut to receive the corrugated sheet. Over this, canvas is tightly stretched. Each frame is 16 by 4.5 ft.; the width of one basket across the frames is 10 ft. A vacuum of 22 in. is used and holds the cake tightly to the basket during transference. With a cake $1\frac{1}{2}$ to $1\frac{3}{4}$ in. thick a basket will hold $4\frac{1}{2}$ to 5 tons slime containing 25% moisture. Filtering takes 45 min., then the cake is washed for 45 min. in the weak-solution vat. At the Waihi 220 tons of slime is treated each day by two baskets. The cost of installation was approximately \$20,000. One man per shift is required to run the filter-plant. The running costs per 24 hr. are 3 men at \$1.92, making \$5.76; cloths

at 1 cent per ton treated, \$2.20; part services of pipe-filter, 72c.; 17 hp. to run 2 vacuum-pumps, \$7.20; power for pneumatic agitation, \$2.40; total, \$18.28, or a little less than 2 cents per ton of ore treated. At the Waihi this means a saving of 30 cents per ton as compared with treating in Johnson presses.

IMPULSE WHEELS of the best modern type for heads of several hundred feet are now provided with combination deflecting nozzles with needle valves, the governors being designed to control the deflection and some other means provided to produce slow movements of the needle valves. Ordinarily with this arrangement the needle valve which regulates the cross-section of the jet is adjusted from time to time by hand as the load varies, so that the governor, in order to maintain constant speed is obliged, most of the time, to direct the stream almost, but not quite, squarely against the moving buckets. When the load increases so that the portion of the stream which is held in reserve by the governor is inadequate to maintain the speed during sudden peaks in the load, the cross-section of the jet is increased either by an attendant or by a small electric motor mounted on the nozzle so that it may move the needle valve in or out very slowly, avoiding the severe strains on the life line which would result from the sudden cutting down of the high pressure stream. Control contacts for the motor are arranged to start it in the proper direction whenever the governor deflects the nozzle away from a predetermined position. This method is much superior to hand control, and it is as safe, for the fastest travel which the motor can give to the needle valve will not create water hammer.

THE distance between levels is generally 100 ft. in the United States, but recently there has been a tendency in the larger mines to increase this distance. In many mines at Butte the bottom levels are 200 ft. apart. At the Camp Bird at Ouray there is a distance of 300 ft. between the main adit and the working level above, but this is broken by intermediate drifts carried through the stopes about 150 ft. above the main adit. The purpose of a level is to develop the orebody and to facilitate the extraction of the ore when found. By increasing the level-interval the cost per ton of development is decreased. In a fairly uniform orebody such as the low-grade monzonite porphyries of Bingham and of Ely, where the copper occurs as a wide-spread dissemination, the levels serve mainly for exploitation. But in patchy ground, where the ore changes rapidly in value, levels are the main means of developing the ore. The more erratic the ore is in character, the closer should be the level-interval, but this should rarely (except in the case of bonanza ground) be closer than 100 ft. In South Africa it has been suggested that, owing to the uniform character of the lodes, a level-interval of 500 ft. should be adopted; but, owing to the narrowness of the conglomerate and the flatness of the beds, this, on account of the cost of getting the broken ore out of such flat stopes, is probably far too great an interval. The character of the ore, whether it is uniform or not, is often not the main determining factor in deciding the distance between levels. The method of mining the ore also plays an important part in this decision. For example, in most veins it would not be practical to have a distance of 400 ft. between levels in case a method of ore-filled stopes was to be used in mining the ore. By the time that stoping would have reached the level above, the hanging wall would be under such a strain that the cost of rendering the walls safe, as the ore was drawn, would be excessive. In all probability the level-interval in orebodies over 10 ft. in width could be advantageously increased to 200 feet.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Deep Thinking.

The Editor:

Sir—Your editorial on "deep thinking and fast sinking" seems to me to be an editorial quibble, an equivocation which may mean much or nothing, and which leaves a chance or loop-hole for its author to crawl out of by a future explanation. With one breath you say that college men are *doing* things in the mining world; with your next, you charge our Eastern mining schools with developing dreamers, and by your comparison attempt to give the University of California a free 'write-up.'

The records of the graduates of the schools you mentioned speak for themselves. Look around you and you will find these men in every walk and phase of the mining industry accomplishing things by deep thinking and sound execution. Unfortunately, they are too busy to spread the reports of their doings with a view to receiving favorable press-notice, so they are overlooked in the mad rush of the others to get into the papers and into the lime-light.

Pride in local institutions is a worthy effort, but, Mr. Editor, do not let your pride in them and your ignorance of the others get the better of your judgment. Columbia, the Tech., Houghton, Lehigh, and the other Eastern mining schools do not deserve the literary jab you have given them while they were busy with deep thinking and earnest doing.

JOSEPH DANIELS.

South Bethlehem, October 11.

[When is a joke not a joke? When the other fellow does not see it. Mr. Daniels will find out that we were intending to be humorous in a kindly way, if he is good-natured enough to read the MINING AND SCIENTIFIC PRESS for a year or so. The Editor is entitled to demur to any charge of "ignorance" of Eastern mining schools and could reply with a force that the incident does not warrant. He has long since outgrown any such provincialism as the idea that any one, or even two, schools of mines are pre-eminently successful in training good men. Cheer up! Lehigh. You are all right, but don't take life so seriously. Earnestness is fine, but let us have a little fun as we go along.—Editor.]

Deep Sinking.

The Editor:

Sir—In your editorials in your weekly issue dated Oct. 5, I notice you publish a note on shaft-sinking and laud the records of Mr. Charles B. Brodigan and Mr. Leslie Simson, which is all in good form and well earned by these men as individuals. I wish to take exception, however, to the manner in which you have drawn the colleges from which they graduated into the subject, and the comment you make about the graduates of other mining schools.

I have always found your columns liberal and impartial heretofore and was surprised to read your sarcastic remark on the abilities of the graduates of Columbia, the Tech., Houghton, and other schools of mines. I am a graduate of Houghton and naturally take pride in the fact. Houghton, or rather the Michigan College of Mines, takes pride in the number of good practical men it has placed in the mining profession. I had charge of some sinking operations in Utah during the summer of 1906 and the results compared very favorably with pre-

vious work of that nature in that particular district. What I wish to contend, however, is that the speed with which a shaft can be sunk depends on the natural conditions, such as the nature of the surface, rock, or vein matter sunk in, labor conditions, equipment, etc., and also largely on the foresight of the man in charge of the work. Very little depends on what particular school he may have graduated from, or in fact whether he graduated from any college or not.

P. S. WILLIAMS.

Chisholm, Minn., October 10.

The Curiosities of Mining.

The Editor:

Sir—The following are some of the points that interested me on my last trip in the interior of Mexico:

1. A cam-shaft, hollow, 5½ in. outside, 4½ in. inside diameter.
2. A 25-stamp mill, 15 days' journey from the railroad, erected in six months.
3. A 75-ton mill using rolls dry remodeled into stamps with wet treatment after running a week.
4. Ore raised 120 ft. in a modern mine on chicken ladders.
5. A 200-ton stamp-mill, pans, concentrators, and settlers, which has never run.
6. Ripe watermelons and snow, within a horizontal distance of 1,000 ft. of each other.
7. A prosperous *vaso* smelting pueblo producing 5,000 oz. gold and silver bullion, from involuntary contributions of neighboring gringo-owned mines.
8. A 100-stamp mill making a profit on 4-oz. silver ore.
9. A *peon* shoveling five tons per day of rich concentrate from a 'waste' launder.

MARK R. LAMB.

Mexico, October 10.

Professional Customs.

[The questions referred to in the next two communications will be found in our issues of October 5 and 19.—Editor.]

The Editor:

Sir—I take pleasure in replying to the contribution of 'T. S.' under the head of 'Searching Questions' in which your correspondent seeks information in respect to the ethics of the mining profession as applied to the conduct of a young man about to undertake his first work. A definition of 'ethics' which comes to hand says: "The science of ethics treats of the nature of the moral agent as an intelligent and free being possessed of a conscience," and a science which deals in "ideas of rightness and oughtness."

In answering these questions categorically I shall assume that our young friend is intelligent and conscientious and that he realizes that the responsibilities are evenly balanced between employer and employee.

1. The man who is young in the mining profession will hardly have much option between taking the work on fee or *per diem* basis; he will have to meet the engagement on the basis upon which it is offered.

2. In the questions that concern the business feature of examination engagements, there should be no reason why a mining engineer should not secure himself in the matter of payment of his fee. I may be more fortunate than other engineers when I can say that I have never in my experience lost a fee. When undertaking examination work it should be in every case the engineer's particular concern to satisfy himself of the ability of his employer to pay the fee agreed upon, and the business

arrangement takes varying form according to knowledge of the client. There is no reason why the preliminary business should be loosely done; it requires, just as much as any other business, that you gauge the responsibility of your prospective client. A formal contract is not required and if the contracting party of the first part is not responsible, a written contract would not help matters much. The preliminaries of mining business should form no exception to any other matters wherein payment of money is contemplated; the agreement should be reduced to writing in letter form, and acknowledgment made in confirmation by the party accepting engagement. When an engagement is made through telegraph it is always subject to confirmation by letter.

3. Terms frequently require the payment of 50%¹ of the fee in advance and the balance upon delivery of the report, or, in cases where the property to be examined lies in a foreign country and the work will occupy a comparatively long time, it is allowable, in lieu of part payment of fee, to draw upon the client for what money is needed. When both parties are responsible, as the assumption requires, such amount can anticipate the expenses of the trip and will be willingly forthcoming.

4. The engineer is supposed to be equipped and outfitted for the work pertaining to mine examination. Such items as sacks and sampling paraphernalia are chargeable to the expense account. In my experience there was an instance where drill-steel, explosives, and blacksmith's forge had to be carried into a part of Mexico almost uninhabited, and where the natives could not handle dynamite. The circumstances permitted the charge for tools and explosives; but such cases are rare.

Don't draw fine distinctions between personal necessities, for in so doing it is easy to throw a sop to one's conscience and trespass upon privilege.

5. Would it not be fair to assume that if a man has reached the time of business responsibility, both in his personal affairs and in the affairs of his employer, that he should be competent in respect to a discriminating sense of what should constitute a just charge as against either himself or his employer. I take the ground that the agitation of this question of expense is of questionable benefit to the mining profession, in that the individual who has important and confidential business entrusted to him is not going to be drilled into conscientious habit in the putting of restraint upon him through any hard and fast rules respecting what is or is not a proper charge. When the employer cannot depend upon the honesty of the employee in these matters he had better make a change in his selection.

Viewing the matter broadly, the expense account is not an account which admits of the personal gain of the individual hired to make a mine examination; as a matter of fact, there are invariably disbursements of a kind which will leave the engineer out of pocket, because they are not fairly chargeable to the employer. In this I am reminded of the story of the accounting of Petroleum V. Nasby on his noted tour of solicitation for the Great Southern University fund, in which the item 'Refreshments, 15c.,' figured many times and with fatal regularity. Speaking from experience, the refreshment item, particularly in the tropics, would not be so individualized and would be proportionately larger.

The budding engineer would do better to leave out the items of 'entertainment' and 'incidentals,' and direct himself to a precise accounting for all expenses, taking receipts for everything and every payment that is subject to receipt ordinarily speaking. Let him keep in mind that there are men in every business who write themselves down as thieves just as soon as the expense

account is left to their personal honesty, and that such men are soon properly classified.

A form of expense account used by one of the large railroad supply companies of the United States in receiving the accounting of its employees is:

Date.	R. R. Fare & Sleeper.	Hotel & Restaurant.	Entertainment.	Incidental.	Totals.	Remarks.
1.....						
2.....						
Etc.....						

6. If given to ordinary business caution there is no excuse for uncertainty about the fee. If the young engineer has not got the sense to secure himself in the payment of his fee, he had better stay at home.

Periodical advices which put in writing the early impressions, incomplete data, and half-digested ideas in advance of the report are to be discouraged. The principals sometimes require a preliminary report which will give them information in advance of the mass of detail belonging to the final report. This is always a reasonable request; periodical reports belong to the office of the local mine management.

7. Since personal interest constitutes a bias on his opinion, a professional man cannot mix up in a stock deal at the time of reporting without directly laying himself open to the imputation of dishonesty. Men very high in the mining profession have run amuck on this very thing in speculating on a stock in advance of their clients.

Just as advice was given to the office clerk in the inception of his career: "Don't begin by emulating Rockefeller," so here I write: Don't emulate the Rockefeller of the mining profession; you will get into trouble. The moral code of some men is the penal code.

Stock dealings in the particular shares of the mine examined subsequent to the discharge of the duty imposed upon the engineer are legitimate. They are dangerous to the young engineer who does not realize that stock manipulation is one thing and the value of stock based on the merits of the mine is another thing, and not necessarily in accord. Whether plans for "private gain" miscarry or not, the man of capital does not employ the young engineer with the idea that a business trust is going to be turned into a private snap.

8. No objection can fairly be made to the circumstance of the engineer having an eye to business opportunity which may present itself within his own time and initiative, provided, of course, that such business is not prejudicial to the interests of the principals to whom the engineer is beholden.

9. Articles descriptive of mining districts, ore deposits, and vein phenomena, etc., are quite commonly prepared from notes made in the course of professional work. In this thing, too, there is the consideration of the interests of the men to whose agency in bringing him onto the ground the engineer is obligated. He will not offend if he uses good sense and discrimination in what he is publishing and weighs the particular circumstances under which publication is made.

10. Ambiguous conclusions and no conclusions are about the same thing. The capitalist or company whom the engineer is serving demands something more than a judgment which 'hedges.' If a man is hired for his judgment on the commercial question involved, which he usually is, he should face the responsibility confided to him and meet the issue squarely. As a matter of fact, as his judgment proves right or wrong in the wake of his whole experience, so abides his measure of success.

In respect to ordering new work at the mine, the engineer hired to report upon the mine and its existing workings would not be justified in spending money for such

account without the authorization from his principals. In any event the engineer would be held personally responsible by the owners of the mine for the expense incurred in the work of re-timbering ground, unwatering main workings, and recovering caved ground—all of it an expenditure for work that the owners of the mine have not seen fit to do.

There are not many beginners in mining engineering who could command such fees as to be able to risk so great a call on their own pocket-book. The "searching question" of the footing of the bills might have too personal an application.

FORBES RICKARD.

Denver, October 4.

The Editor:

Sir—It does not seem to me that the questions propounded by T. S. can be properly answered without knowing all the details, business and technical, concerned in the point at issue; namely, should an investment be made in a certain mine situated in the tropics. In this matter, common sense is all important and without it the report will be of little value in any case. However, the general principles to be applied should always be the same. The engineer should be animated by a desire to get as much and as correct information about the property as is practicable, and this information should be regarded as belonging exclusively to the employer. The same would apply to all general information gathered in the course of the trip. Thus, is the government a stable one and are the rights of foreigners respected? Is labor abundant and good? Is there a fund reserved for development? Is all of the stock issued? Is the management safe and so forth? The answers to these questions may be quite as important in determining the advisability of the investment as the intrinsic value of the property.

1. If the time required for the examination is known, it is better to charge a definite fee.

2. With reliable people, a letter signed by the principals is sufficient guarantee of payment, moreover, the law protects the engineer in the matter of reasonable fees.

3. A substantial advance on a long trip should be made and few reliable companies or principals will object to this. The engineer goes out to make or save money for his employers and not in his own interests.

4. An engineer usually has many of the instruments required for the work but any special equipment necessary to determine the value of the property or to facilitate the journey, should be paid for by the employers.

5. In regard to traveling expenses:

(a) Ammunition and medicines might easily be legitimate expenses, but hardly tobacco and laundry.

(b) The engineer is entitled to good accommodations throughout the trip if they are to be had; but the engineer who squeals at hardships has missed his vocation.

(c) The expense account should be for expenses actually incurred.

(d) Charges for necessary incidentals are proper.

(e) Vouchers for important expenses should accompany the expense account, except for railroad and steamboat fares, etc., where a definite amount is charged and known and where there is usually not time to secure vouchers.

(f) Disbursements incurred in getting pertinent information would usually be called legitimate expenses.

(g) The expense account should usually be rendered at the close of the work, but this is a matter to be determined between the parties interested.

6. In some cases a preliminary report may be valuable to the employer, and in such cases should be rendered

with due qualifications. Few companies or principals will want to invest until all of the facts are known.

7. If it has been definitely determined that the shares are selling for less than their real value, the principals should know this at once. It is bad policy for the engineer to be financially interested in the property under investigation, and if shares are bought by the engineer for himself, it should be done with the permission of his principals.

8. Few employers will object to an engineer taking advantage of the trip to get options on other properties under such conditions as in no way interfere with their interests, but the fact should be made known to the principals.

9. Since all general information relating to any district has an important bearing on any investment in that district, this information should be the exclusive property of the employer until such time as it no longer concerns his interests. In any case, it is good form to ask permission to publish articles, the material for which is gathered at the expense of another.

10. An engineer should say 'Yes' only when, in his judgment, all the conditions justify it. If there are reasonable doubts, the employer himself can best decide if, or not, he will take the risk.

Cleaning out old works should usually be done by the mine owners; but often this is impracticable. Then it may be regarded as a necessary expense, if vital to the determination of the value of the property.

H. W. TURNER.

Portland, October 2.

ACTIVITY IN CHIHUAHUA.—Mining in northern Mexico is active. Since January, 77 ore invoices covering shipments to the United States have been certified by this consulate, the total aggregate amounting to \$233,201. There is a daily train service from Ciudad Juarez into the Interior by the Mexican Central trunk line. The Rio Grande, Sierra Madre & Pacifico has a tri-weekly service, and is built wholly within this consular district. Its present terminus is Casas Grandes, 158 miles from Juarez, but the road is being extended into the timbered districts. The same company is extending the road from the timbered districts at Medara, and will continue until the two projections meet. There is to be an extension of the same road to the coast. Lumbering is a new industry, and judging from the progress made in the past few months it is apparently a profitable one. As yet no lumber has been exported, as all the necessary timber machinery has not been received and put in operation. At present there are in operation and in course of construction an extensive drying shed, sawmills having a capacity of 500,000 ft. of lumber per day, a 45-acre storing and floating lake, planing mills, and turpentine stills.—U. S. Consul at Ciudad Juarez.

SULPHUR IN BALUCHISTAN.—The geological department of Baluchistan has made an examination of the sulphur mines of Sanni, in the Siwalik sandstones and clays. The mines have not been worked for many years and have collapsed to such an extent that they have become very difficult of access; besides which parts of them have caught fire; some of the clay bands are said to be so full of sulphur that they burn readily. The amount of sulphur impregnating the rock seems, it is believed, quite sufficient to hold out prospects of remunerative working, especially taking into account the favorable situation of the mines at the edge of the Minhi plain. In the neighborhood of the sulphur mines the rock is traversed by numerous veins of alunite.

The Mt. Morgan Mine.

The accompanying photographs of the great Mt. Morgan mine will prove interesting. This mine is 25 miles southwest from Rockhampton, in Queensland, Australia. The Mt. Morgan is one of the grand ore deposits of the world, for it had yielded 3,079,695 oz. of gold up to the end of 1906; the total output has been worth \$60,964,087, and out of this there has been paid \$32,757,705 in dividends. To these figures can be added the output for 1907, which will be worth about \$5,000,000. This has been done in twenty years. The original property consisted of a 'selection' of 640 acres taken up, for the purpose of grazing, by Donald Gordon, in 1873. Becoming acquainted with the brothers Morgan, who also held land in the district, he showed them one day a piece of gold-bearing quartz, which he had picked up in Mundie creek. This stream flows at the base of the hill called Mt. Morgan; it is only 500 ft. above the surrounding country, and

Fig. 1. Mt. Morgan Mine.

Steam-shovel in foreground of an open-cut. Old square sets in background.

1,225 ft. above sea-level—at least, it was; for mining operations have removed the crest of the mount, which has become a huge quarry of gold ore. Gordon agreed to show the Morgans where he found the rich 'float,' and in return he is said to have received £20 and as much whiskey as he could drink. On the low wooded hill overlooking the creek he pointed out to them the silicious ironstone. This exhibited gold in places; the Morgans sent samples to Sydney, and the results of the assays proved the ore to be richer than it looked. They purchased Gordon's holding of 640 acres for £1 per acre, that is, about \$3,200. From this ground a profit of over \$32,000,000 has been won!

The three Morgans subsequently sold, first a part, and eventually the whole, of their interest in the property. In 1886 a company was formed with a capital of one million shares of £1 each. These shares rose in 1888 to £17 5s., giving the mine a market value of over \$86,000,000. These shares are now quoted at £4. Many fortunes have been made, and lost, in the twenty years during which the mine has been so productive, for, to quote the language of a managing director at one of the

annual meetings, "Mt. Morgan is after all only a gold mine, and is consequently subject to the vicissitudes of all mineral formations." The thing to do is to get on the side of the right 'vicissitude,' and not stay there too long.

For several years the ore was broken in benches, 30 ft. high and 300 ft. long. A central shaft connected these with the main adits. The drilling was done with 'jumpers' or long bars of steel, raised and dropped by hand. As underground exploration advanced, the hill became dissected by cross-cuts, and finally a deep shaft was sunk below the level of the creek at the base of Mt. Morgan. Deeper exploration found sulphide ore under the silicious ironstone of the big gossan, and beyond the body of gold ore there was discovered a copper deposit, containing some gold also. Last year a copper smelter was completed, and now this mine produces 4,000 tons of copper per annum.

Fig. 2. Head-Frame at Mt. Morgan.

A correspondent, who recently visited the mine, writes to us saying: "The big deposit is worked as an open-cut (Fig. 1), the system employed resembling that adopted at Mt. Lyell. The mill-holes from the surface lead to floors supported by square sets. Here an electric motor draws the loaded cars to the side of the hill. The position of the mill-holes is largely governed by the position of the andesite dikes which cut through the ore deposit.

"People speak of the 'gold lode' and the 'copper lode' as if they were two distinct things; as a matter of fact they are one and the same; the portion of the orebody that is sent to the smelters carries more copper and less gold, while the portion sent to the chlorination works is silicious, and contains more gold and less copper. The two parts are roughly separated by a dike. The ore is really a large body of shattered Gympie formation, mostly quartzite, cut through with dikes and impregnated with pyrite. The 'gold lode' is worked by the square-set system, because it is considered unprofitable to mine the whole formation, and that by using the square-set system they can work out a small portion and leave the rest; but on looking over the plans, it seems that they are encroaching on what was formerly considered unpayable 'stone,' and it is highly probable that it would pay

better to work the gold as an open stope as they do the 'copper lode;' it would be cheaper and they would not lose anything. The head-frame and ore-bins (Fig. 2) constitute a good structure, designed by some graduates of Sydney University. Being for an underlay shaft, there were no complicated strains to work out, but it is

Fig. 3. Mt. Morgan Mine, Queensland.

Illustrating mill-hole system in open-cut.

well built all the same, and the crusher on it does not give any vibration at all. The rails are fastened to the sills of the shaft sets which are concreted in position. The steam-shovels (Fig. 3) are only used for stripping. There is one central electric station that supplies the necessary power. The hoisting is done by an electric hoist, the indicator of which, when it goes past a certain point, works a cut-out switch; this stops the engine and prevents overwinding. The water-jackets have the inside portion of copper plate, while the outside is steel. It is intended to build one large circular forehearth instead of two smaller ones. The lower jacket goes right to the bottom of the furnace. A so-called vaporiser is used with each of the furnaces. This is a tank, shown in the photograph (Fig. 4), into which the heated water from the jackets pass. At the bottom of this the air-pipe is let in. The air is partly heated by the water and the water is partly cooled by the air. This arrangement is found to save two-thirds of the water. The slag-pots are run out to the dump on a mono-rail overhead. A movable terminus hangs well over the tip, and when necessary another section of about 20 ft. is inserted between this and the fixed rail."

The general manager is G. A. Richard and his assistant is H. P. Searle. Both of these engineers recently visited the chief mining regions of America, seeking progressive ideas. One result was the decision to treat the blister copper locally; in furtherance of this idea, the Mt. Morgan Gold Mining Co. took a large interest in a company formed to erect an electrolytic copper refinery. This refinery was built by Hirsch & Son of Halberstadt, Germany.

Tantalum.

The fruitful activity in experimental metallurgical work during recent years for both scientific and commercial purposes, especially in electro-metallurgy, has made possible the reduction of metals that were before unutilized and almost unknown. The determination of the properties of these metals has suggested uses for them, with the result that there is a growing demand for ores that but a few years ago were sought only as mineral curiosities.

One of the most remarkable of these metals is tantalum. It is not attacked by hydrochloric, nitric, or sulphuric acids, aqua regia, and alkaline solutions. It can be drawn into fine wire having a tensile strength greater than soft steel. A red-hot lump of tantalum may be at once hammered into a plate which, on repeated re-hammering, becomes as hard as diamond. A diamond-drill, running continuously for three days at 5,000 revolutions per minute, failed to penetrate such a plate, although it was but one millimetre thick, while the drill was much worn. A British patent has been obtained for making writing pens from tantalum, whose hardness, elasticity, and resistance to corrosion would seem to fit it

well for such use.

Tantalum is now employed principally as a filament in an electric incandescent lamp, which was put on the American market in 1906. This lamp consumes but two watts per candlepower, as against more than three

Fig. 4. The Copper Smelter at Mt. Morgan.

watts per candlepower for the ordinary carbon filament lamp.

ITALIAN AND JAPANESE ANTIMONY.—Large quantities of antimony are mined at Pinerola, near Turin, and throughout the Sardinian islands, some of it being exported. The recent great decline in the value of antimony is due solely to Japan having offered it at about \$16 per quintal (of 220 lb.), a price which is deemed low in Italy.

The Copper Situation.

By JAMES DOUGLAS.

*There has been for the last 10 years an average rate of 84 tons of iron consumed to 1 ton of copper. The world's demand for the two metals was in the same ratio, and the world's production of copper also shows a notable percentage decrease. The production was in 1897, 405,350 tons, and in 1906, 718,368 tons, or an average increase for 10 years of 4.3%, whereas between the production of 1905, which was 699,504 tons, and that of 1906, there was a gain of only 15,754 tons, or 2.03%; hence the rise in price. That iron did not sympathize in price is due to the fact that the undeveloped resources of iron ore and the metallurgical appliances for its reduction to metal, are much greater than those of copper. Consequently iron can bear a temporary strain better than copper. Moreover, the standard price for iron has been fixed at a figure high enough to compensate for wide variations in the market.

Between the price of rails early in 1897 of \$16 per ton, and the present price of \$28 per ton, there is, however, as wide a difference as between the price of copper in 1896, \$10.88, and the price of copper in 1906, \$19.62. But there can be a policy pursued in regulating the home prices on iron which cannot be followed in the case of copper. Iron is protected; copper is not; and, therefore, if desired by the large manufacturers of iron to maintain a staple price, the very large margin of \$11.20 per ton of steel and of \$4 per ton of pig iron, which the duty gives them, may be used. In case of a low foreign price, a high domestic price can be sustained; or in case of high foreign price, the domestic price may be maintained at a given standard up to the limit of the duty. The McKinley bill struck off all duty on crude and refined copper, though retaining it on manufactured copper. Thus, the world's price regulates the American domestic price, and the copper producers have been saved from any temptation to form a copper trust, in order to derive the benefit of the duty. As to the regulation of price, considering our supreme position as producers, it may be more proper to say that we fix the price of the world. For a short period this year, the English price ruled slightly lower than the price demanded in the United States, and copper immediately commenced to flow in from abroad, although over any considerable period of time, say the past ten years, 54.5% of our production has been exported and we make 54.7% of the world's total.

In spite of the active demand and the high price, last year's domestic production showed that there were only two years, since copper became a prominent article of domestic production, when copper production showed as slight a percentage of gain. A steadily progressive high percentage increase, however, cannot be maintained and should not be expected when the gross increase reaches certain limits. For instance, in 1896, when the percentage of increase over 1895 was 21%, the actual increase was 81,168,640 lb.; but during the last decade, the production has increased at such a rate that the 4.8% increase of 1906 over 1905 represents an actual increase of 42,378,560 lb. of copper—an increase of 137.4% over the production of 1895, or 451.1% over that of 1885.

Still, it is significant that this notable falling off in percentage increase should occur when the high price of copper may be supposed to have served as a stimulus to the utmost activity. The world's increase, as well as our own, showed a diminished percentage of increase—being 2.16% instead of 6.16% of the previous years. To explain this anomaly, it must be borne in mind that as

the average of the per cent of the ore treated was probably lower, more ore in proportion to the output of copper was probably mined. When copper is 20c., money can be made out of ore which is valueless with copper standing at 12c.; and, therefore, should the contents of the mines permit of selection, ore is utilized at one time which at another time is rejected. Moreover, the average percentage of ore of the great mines of the country is declining, and will continue to decline. Rich bodies of secondary deposits may be discovered in any deep mine, which may arrest the decline in its average yield, but the world's experience is not likely to be reversed in our favor—more especially as it coincides with our own—that the average yield of deep copper mines declines with depth; and as with declining yield generally occurs the increased cost of mining incident to greater depth, two factors concur to bring about the reduced production, which must occur sooner or later.

In comparing iron and copper mining, and the ease with which the varying demands of trade may be met by the producers, it must be remembered that two tons of average iron ore from the most prolific source now available—Lake Superior—will make one ton of metal; whereas from 33 to 75 tons (say an average of 50 tons) of copper ore must be mined to produce one ton of copper. A sudden increase in demand for the baser metal can be more readily met than when such a call is made for the rarer. The relative supply in nature may be gauged by the value on which the price of each is made, the value of iron being generally quoted by the ton, and of copper by the pound. Last year's production of iron was made from approximately 50,000,000 tons of ore. Our copper mines, to yield a production of 900,000,000 lb., must have handled approximately 22,000,000 tons of ore, or nearly half the quantity of ore raised from our iron mines. The ore of iron, moreover, occurs in very large deposits, worked in some cases by steam shovels, whereas our copper comes from comparatively narrow veins or irregular masses.

Referring to the relative growth and decline of the three principal sources of the metal since the Western States began to grow into prominence, say from 1882, we find that at that date the Lakes supplied from ores of metallic copper 25,000 long tons of copper; Arizona, from oxidized ores, 8,000 long tons of copper; and Montana, from sulphide ores, 4,000 long tons. After that, the Lake production relatively declined. The Montana production continued to increase rapidly until 1887, when Montana took the first place with 35,000 tons, Lake Superior second place with 34,000, and Arizona third, with 8,000. This order was maintained until 1905, when Arizona attained the second rank.

The largest sources of new supply, which can be counted on with tolerable certainty, will be found in the low-grade ores of Utah and Nevada, where works on a very large scale are being planned or erected for their treatment.

The presence of small quantities of gold and silver in copper ores, now that the process of electrolytic copper refining permits these elements to be cheaply separated among the impurities, is putting within the range of profitable extraction ores of very low percentage in copper. When the Anaconda mine was first opened and its rich ores (and subsequently the mattes, made from them) were shipped to Europe for refining, the margin of gold and silver deducted from the ton of copper, before any allowance was made to the shipper, was \$60. As this deduction was substantially the whole of the precious metals in the Butte copper, the company derived no benefit. Whatever margin there was in the \$60 over and above the cost of separation went to the refiners.

*From *The Engineering Magazine*, October 1907.

Most of the rich argentiferous copper was then converted into bluestone. But since electrolysis has been applied to copper refining, and the process has been carried out on a large scale, the commercial charges for refining the copper and separating the precious metals have been reduced from \$60 to \$16, and as the value of the electrolytically refined copper is ordinarily about \$10 per ton above that of furnace-refined copper, copper bars containing \$6 in precious metals can be economically converted into electrolytic, and their gold and silver added to the world's wealth. If the copper bars contain the concentrated gold and silver of 30 tons of ore, the ore need contain only 20 cents of gold and silver per ton to make it profitable to submit the resulting copper to electrolysis. The amount thus extracted from domestic and foreign ores in the refineries of the United States is approximately: From Montana, \$6,650,000; Arizona and Sonora, \$2,105,000; Canada, \$460,000; and other sources, \$2,500,000—or over \$11,000,000—most of which formerly entered the refined copper and was wasted.

While the presence of precious metals in high-grade ores redounds to the fortunate copper company which mines them, when ores of 2 per cent and under (like those of the Boundary district of British Columbia, or Bingham canyon in Utah, or of Ely county in Nevada) are treated, the addition of \$2 or \$3 in gold and silver per ton may convert an unprofitable into a very profitable mineral. And from such ores will probably come much of the copper from our new mineral developments; for it is not probable that within the explored territory, many new large deposits will be discovered which are also of high grade, whereas lean ores in very large quantities are known to exist in many districts of the country. Apart from their contents in precious metals, better machinery and improved metallurgical methods permit of ores being treated economically today which would not have been classed as ore a few years ago; and today ores are rejected in developed mines which at no distant day may help us to maintain our position in the copper world.

To forecast the future of copper is impossible. It is safe to predict that, if no substitute is discovered and the demand for the metal increases as it has done during the modern industrial era, the supply will fall short of the demand and the value of the metal will rise. The same is true of all the mineral products that are consumed in the arts. The experience of the last few years in the United States illustrates, however, the sensitive connection between demand and price.

While such spasmodic variations are transitory, there can be no doubt that if the demand grows and no very important new discoveries are made, the metal will become scarcer and will command a higher price than the average price of the past. One consequence, which will also be a corrective, will be that the metal will cease to be used for purposes to which it is turned today, and for which a cheaper material can be discovered. For it is an invariable rule that when the metal has run up above a figure which deters purchasers from using it except for unavoidable purposes, the consumption drops off sharply, and a more normal value is restored.

A review of the world's mines would seem to indicate that the old mines are approaching exhaustion, that no new large deposits of rich ore, except possibly those of Tanganyika, are in sight; and therefore the trade must turn to deposits of lower grade than have heretofore been worked, if the demand continues as active as at present. And copper cannot be made as cheaply from mines of that class as from the mines we have been drawing upon so recklessly for a generation.

The next question bearing upon values is that of probable consumption. The three principal uses to which

copper is now turned are: The manufacture of electrical machinery and the transmission of electrical current; in the composition of alloys, principally brass, for stationary engines, locomotives, railroad cars, automobiles, and for arms and ammunition, and in architecture; where it replaces iron and lead.

Glancing at the three sources of consumption, the draft on copper for telegraph wires, trolley lines, long-distance transmission, and other electrical purposes, is of comparatively recent date, and is doubtless very large—probably about one-third of the world's supply goes into this new industry; but comparatively little of it is actually consumed, though a great deal of it is through carelessness wasted during the installation of plants. The copper remains in service with little waste, or goes back to the refineries as scrap. But the demand for this purpose will not fall off. The urban and interurban mileage of trolley lines in the United States is between 30,000 and 40,000 miles. They have been built within very recent years, and new lines are reticulating the country. No substitute for copper in this class of roads has been suggested, for though aluminum may indifferently replace copper for current transmission, it cannot bear the wear and tear of the trolley. Gradually, also, the motor will displace the locomotive on all our present steam roads where traffic is dense; and though the third rail instead of the trolley wire will be used, the amount of copper which goes into the transmission, the generators, the motors, and all subsidiary appliances, will increase the proportionate demand for the metal by electricians.

The amount of copper which enters brass and other alloys it is difficult to determine. From information derived from several of our large railroad systems I would infer that about 5 grains of copper are consumed and actually go out of existence per car mile. This would represent about 5,000 tons of copper consumed by our railroads per annum for this purpose alone. Automobiles must make a new and very heavy call on copper, and the demand for stationary engines and steamboats is increasing with the growing industrial activity of the country. The quantity used up in war material and ammunition—during peace and war—is very great. In spite of probable fluctuations in the brass trade, there will be a large and satisfactory average growth.

But when we come to the third principal use for copper, that is, in the building and house-furnishing trade, we find it playing the part of an article of luxury. Our forefathers were satisfied with wrought-iron railings in their city houses, beautiful examples of which still exist in all the west-side streets of the old residential portion of New York City. Now we must have bronze balustrades in our palatial offices, hotels, and private buildings. Brass or bronze hinges or locks, gas fixtures, etc., appear in profusion in our houses and railroad cars, and brass and copper have driven out lead for roofing and plumbing. When copper is abundant and sells at a moderate price, it is the most desirable material for these purposes, but as it becomes rarer and dearer, substitutes for it will be used. As long, however, as money is forthcoming, the public taste for brass or bronze will be gratified, and probably more of the world's supply will go into architecture and house-furnishing than in any other use.

From the above review of the sources of supply and the sources of demand, it would seem that while there is no risk of copper becoming a rare metal in the near future, it will certainly have to be extracted from much leaner ores at an increased cost. Also while there is no reason to believe that its consumption in the arts will grow less, there are metals which can be substituted for it, should the popular taste or financial exigencies require.

The Charging of Blast-Furnaces.

Written for the MINING AND SCIENTIFIC PRESS
By E. H. MESSITER.

*The basic feature of the arrangement here described is the ore-bedding system designed and patented by the writer and manufactured by the Robins Conveying Belt Co. This consists of (1) suitable arrangements for transferring the ingredients of the charge from railroad cars to belt-conveyors, (2) means for crushing and sampling, (3) a

The great flexibility in the design of the plant resulting from the use of the belt-conveyor is of particular advantage at this point. Duplicate crushers may be used to give different sizes for different materials, and as many sampling units as desired may be introduced to give facilities for cleaning and to provide for different classes of ore. Likewise it is a simple matter to introduce screens for the purpose of diverting fine material from the blast-furnace plant as in the case of a copper reduction works using both shaft furnaces and reverberatories.

The storage beds are made by depositing the charge ingredients in long narrow piles of triangular cross-section in such a way that the piles are uniform as to composition and physical character throughout their length. No attempt is made to secure uniformity transversely to the bed. In other words, every cross-section of the bed is exactly like every other cross-section, while one material may predominate in the top or bottom of every

Fig. 1.

bedding and storage plant, and (4) devices for delivering the charge from the belt-conveyor system to the furnaces.

The first operation involves the use of bins or hoppers and proper devices for delivering their contents to the belt-conveyor. The traveling shaker feeder is admirably adapted for this purpose. Fig. 1 shows a series of receiving bins with conveyor and feeder-car. The bin-gates are made large and stand wide open while the feeder is in position below.

The shaker-feeder car is a hopper mounted on a carriage astride of the conveyor and having a reciprocating pan under its discharge opening. The pan is so placed as to prevent any flow of ore over it unless it is in motion. Its stroke

and inclination are adjustable, as is also the size of the outlet of the hopper. An electric motor on the carriage imparts motion to the pan and propels the carriage itself when desired. In connection with suitable bin-gates the whole constitutes a device for delivering the contents of the bins to a belt-conveyor with the least possible labor and the fewest possible interruptions.

The crushing and sampling are accomplished by machines selected to suit the requirements of the work.

section and the coarse material may predominate at the bottom and sides.

By removing material simultaneously from all parts of the cross-section of the bed, as is done by the reclaiming

Fig. 2.

machine, the mixture obtained will not vary from one end of the bed to the other.

The photograph, Fig. 2, shows the skeleton structures carrying the belt-conveyors over the beds, the reclaiming machine and the receiving conveyor at the right of the picture. The overhead conveyors are equipped with special ore-bedding trippers traveling at such a speed that very little is deposited in one place at a time. The result is a bed of the character described above. Such a bed is seen in the photograph on the left. The ore-bedding tripper is a carriage astride of the conveyor,

*A few notes on this interesting development in metallurgical practice appeared in our issue of April 27, 1907. The subject warrants the full account given herewith.—Editor.

equipped with two pulleys, around which the conveyor-belt passes in the form of a letter S. On the shaft of one of the pulleys are two traction wheels, the alternate engagement of which with the rails and with fixed brakes determines the motion of the tripper. The total number of parts in the tripper is small and the wearing parts are few and inexpensive.

The reclaiming machine is a traveling bridge spanning the width of the bed and its trench-conveyor. Under the forward side of the bridge is suspended a scraper-conveyor of special design, operating in a steel trough consisting of a nearly horizontal bottom plate and a vertical back plate. The conveyor flights are inclined to the axis of the conveyor and are provided at their front ends with plough-shaped extensions which project beyond the bottom plate. All material within reach of these flights is swept onto the plate and carried along to the end of the machine, where it falls through a short chute to the trench-conveyor.

A triangular harrow, covering the entire cross-section of the bed, is mounted in front of the machine so as to be adjustable as to its inclination and to be slowly but powerfully moved back and forth. The relation between the spacing of the harrow points and the stroke is such as to dislodge material in a continuous manner from all parts of the face of the bed, which material rolls down to the conveyor and is carried by it as described above. An electric motor with simple geared connections drives the conveyor and harrow. An additional motor of smaller size is connected with the wheels on which the bridge rests and is geared to advance the machine automatically into the pile at any desired rate or to run the machine forward or backward at a higher speed when it is being transferred from one bed to another. The movement of the machine from one set of tracks to another is accomplished by means of a motor-driven transfer car. A reserve machine may be kept in a repair shed placed alongside the transfer-car track.

For proper storage capacities (such as are provided in all the larger smelting plants) the first cost of the bedding conveyors with their supporting structures, the trench-conveyors, and two reclaiming machines with transfer car (in other words, the whole first cost of the storage and reclaiming system) is less per ton of capacity than that of any type of bins from which the ore can be drawn by gravity. When the extremely low operating cost incurred at the beds is considered, it becomes evident that this system has everything to commend it as a simple storage plant even where bedding is not a necessary feature of the process.

The trench-conveyors alongside the beds connect with one or more other conveyors which deliver the complete mixed charge in the furnace-house. The charge can be deposited on the feed-floor for hand feeding, or in bins from which it is fed into the furnace, or any one of a number of types of mechanical feeders may be used. It can always be arranged to feed the fuel separately if considered necessary. The whole cost of handling from car to furnace becomes a small fraction of the cost by the usual methods, and metallurgical and other advantages of far-reaching importance are obtained.

Fig. 3 shows a typical arrangement of plant. There are three unloading tracks built on low trestles. Under two of these tracks are placed a number of receiving-hoppers, while the third is so placed as to permit cars to be unloaded from it directly into the sampling-mill. Conveyors A1 and A2 are placed under the receiving-hoppers and a traveling shaker-feeder is provided for each conveyor. Conveyor B receives the material carried by A1 and A2, and delivers either to a crusher or to conveyor C, which in turn delivers either to the sam-

pling apparatus or to conveyor D. A traveling tripper on conveyor D will discharge at will to either of the bedding-conveyors E1, E2, E3, which are placed in the skeleton structures over the beds. These conveyors extend over the entire length of the beds and are equipped with high-speed ore-bedding trippers.

Rails are laid on the ground on each side of each bed for the reclaiming machine, which removes the material from the bed and delivers it to conveyors F1, F2, F3, placed in trenches parallel to the beds. Conveyor G is arranged to receive from either of conveyors F1, F2, F3, and to deliver to conveyor H, which runs through the furnace-house over the several furnaces.

With the exception of small lots of high-grade ore, which it may be desirable to unload directly from track No. 3 into the sampling mill, all incoming ore, fuel, and flux will be unloaded into the receiving bins on tracks 1 and 2. Starting with the bins empty, a day's receipts are unloaded into them, selecting the bins in any way with the single precaution that all of the material in any one bin shall belong to the same lot. Any one lot, how-

Fig. 3.

ever, may occupy as many bins as necessary. For each carload there will be a card or ticket left at the bin, giving the lot number and any other information necessary.

When ready to commence bedding, the operator on the shaker-feed car will receive a signal from the operator at the samplers indicating that the conveyors to the bed and the samplers, etc., are running and ready to receive ore. The feeder operator will then open one of the bin-gates wide and start the feeder. After the first bin is empty, if any other bin in either row contains ore belonging to the same lot, the shaker-feed car will at once travel to it and empty it in the same manner. When the last of any lot is delivered to the conveyor the feeder operator will signal the sampler operator and the latter will set the deflecting chute at the top of the sampling tower into position for delivery to the samplers, which were idle during the passage of the previous lot, and signal the feeder operator when it is done.

The feeder operator now sends along the second lot in the same manner. During the passage of the second lot, the sampler operator will remove the one one-hundredth sample of the first lot, attaching the identification card or cards which will have been sent to him from the unloading bins. He will then clean the idle sampler and crusher, and wait for the signal announcing the end of the second lot. This routine is continued until all the bins are empty. Thus the duties of the feeder operator and the sampler operator constitute all the control that is required in the bedding operation. A conveyor operator or oiler will patrol the conveyor lines and attend to sweeping and lubrication. The grease-cups will need only

to be turned slightly every day or two and be filled, perhaps, once a month.

When returned slag is included in the charge, the manner of placing it on the beds will depend on circumstances. In general, a crusher placed where the slag shells are dumped and a conveyor delivering to conveyor D will suffice. If it is more convenient to transfer the slag in railroad cars, it will be unloaded into the receiving hoppers and be sent to the beds in the same manner as the other materials. In like manner the handling of briquettes, if any, will depend on local conditions. If dried in the open air, the wet briquettes can be piled along the edge of the bed next to the belt-conveyor, into which they will be gently swept by the reclaiming machine. This will avoid a second handling.

The beds themselves will now be considered with reference to the process of making up the charge in them. The cycle of each of the beds consists of three stages. In its first stage a bed constitutes an overflow receptacle for the materials on hand over and above what is needed for the bed in the second stage. The bed next enters its second stage during which it is, or becomes, a reserve bed ready for use when the one ahead of it is exhausted. In its third stage, the bed constitutes the immediate supply of the furnaces.

In a plant employing three beds there will be at any particular time one bed in each of the three stages. Assuming beds of 10,000 tons each, let us say that this is one week's supply. Then a complete cycle for any bed will occur every three weeks and any bed will continue in the same stage for one week. In any particular week, the bed which is in the third stage will be in use, supplying the furnaces. The ore, fuel, and flux received during the week will be deposited in one or both of the other beds, according to circumstances. If the second-stage bed is full and of the desired composition, the week's receipts will all go into the first-stage (overflow) bed. If the second-stage bed is partly filled or empty the week's receipts will be used, first to complete this bed, and the excess, if any, will go into the first-stage bed.

In carrying out this operation, the total weights of SiO_2 , FeO , CaO , etc., that are wanted in each bed will be decided upon and before a carload is ordered to the unloading bins, it will be determined which bed is to receive it, and this will be indicated on the card that accompanies the car. When the desired quantity of any particular component of the charge has been put into a bed, the bed is complete as far as that component is concerned and subsequent receipts of that class of material will go into the next bed. Only one rule is necessary for any carload of charge material, namely, send it to the second-stage (reserve) bed unless its contents would raise the total quantity of any component in that bed above the assigned limit in which case it must go to the first-stage (overflow) bed unless it would exceed the limit there also.

The latter event will occur only when the whole storage capacity in the beds for some particular element is used. The situation is parallel to what would occur in the system now in use if all the bins assignable to a particular ingredient were full. When it occurs, the car must either be held until another bed is started or unloaded elsewhere. When one bed has just become empty and another started there is room to store three weeks' supply of any and all components, but just before a bed is used up and before it can receive any new ore, there is room for only two weeks' supply. Consequently, the necessity of holding any car or of unloading it elsewhere can occur only when there is from two to three weeks' supply ahead of the material contained in it. A fourth bed can be added at any time or at the start if desired.

There would then always be three beds or 30,000 tons available in addition to the bed in use.

When the receipts of ore, etc., fall below the requirements, the amount on hand, at the beginning of the period of shortage, will determine the length of time the shortage can continue without the necessity of shutting down furnaces or of changing the charge. It will be exactly the same length of time that would elapse if the same quantity were stored in separate bins and the same charge were run. With a continued shortage, the quantity on hand in the reserve bed will be smaller and smaller until it becomes so small that it cannot be brought up to the full tonnage by the end of the week. After that, if the shortage continues, the size of the bed will be gradually reduced, each successive bed containing as much charge as can be made up from the materials received while the preceding bed lasts. During such a period there is no change of routine and no departure from the general rule given above for the disposition of any carload. We simply change often from one bed to another, and this may be continued without any inconvenience until the beds become so small that they last only a day or half a day.

Briefly, if at any particular time there is two weeks' supply in the beds and there occurs a protracted shortage amounting to one day's supply per week, it will be 14 weeks before the charge must be changed or furnaces blown out or other storage drawn on. If the shortage occurs in any one essential ingredient as silica, fuel, or lime, at the rate of one day's supply per week, it will likewise be 14 weeks before one of the above changes will have to be made. In the one case, the third or overflow bed will disappear, but in the second it will not, but will become devoid of the particular ingredient which is running short, and can at once be restored to proper composition if a supply of that ingredient comes in.

The arrangement of the apparatus by no means limits the operations to the scheme above outlined, as will be seen from the following remarks:

1. The reclaiming machine will operate equally well on a bed of any cross-section up to the maximum.
2. The travel of the ore-bedding tripper is adjustable.
3. Any bed may be put into use at any time its contents have the proper composition for smelting, no matter how small the total quantity in it.
4. Any bed may be put into use while partly full and can be brought up to full cross-section, while it is supplying the furnaces by adjusting the travel of the tripper to cover a part of the length of the bed.
5. Either bedding space may be used for several short beds instead of one long one.
6. The composition of a bed may be changed while it is in use.
7. A carload of any material placed in a bed through error, cannot alter the percentage of any ingredient more than one-third of one per cent, nor measurably increase the cross-section of the bed. One hundred tons added to a full bed will increase its width about one inch on each side.
8. When it is desired to adjust the composition of a bed, the adjustment may be made to apply to any part of the bed, however small, by limiting the travel of the tripper to that part of the bed.

A narrow chute placed in the path of the stream from the traveling tripper will collect a perfect sample of the material that goes into the bed. It will take the whole stream part of the time at regular intervals. In making up a bed, ore and flux can be put into it for several days with general knowledge of the ores as a guide. An analysis of the sample of the bed will then be made the basis for subsequent additions. By making an analysis a

day or half a day before the bed is finished it can be brought very accurately to any desired composition.

If after a few hours' run this charge is found not to be just what is wanted, it can be corrected immediately. Three of the 24 unloading bins can be reserved for this purpose, with 125 tons of silicious or iron ore or lime-rock in each. One of these bins will make a variation of $1\frac{1}{4}\%$ in a whole bed and its contents can be put on the bed in 30 minutes. If a larger variation is required it may be applied to part of the bed in front of the reclaiming machine and the remainder of the bed adjusted at leisure. One hundred and twenty-five tons added to 125 ft. of bed will make a change of 5% in 30 minutes and will run the plant for 40 hours.

The supply from the beds to the furnaces will be accomplished by operations of the simplest character. The reclaimer operator has only to adjust the speed of travel of the machine along its track to suit the average rate of running of the furnaces. In other words, his only duty is to keep the receiving bins supplied. He will be guided in this by an occasional signal from the operator on the feed-floor.

The total cost of operation can be closely estimated in advance for any given local conditions. The system is in use as a whole or in part in several smelters and aside from this, there are ample data with which to estimate the cost of conveying on belts. It may be said that the total cost of handling from the unloading bins into the smelting column will generally amount to from 5 to 7 cents per ton. This includes labor, power, belt-renewals, and other repairs. The cost of unloading cars is to be added, and will, of course, depend on the kind of cars in which the material is received and on other matters. On account of the fact that all of the unloading is done at one place where the best facilities can be provided, it will generally be true that with this system the cost of unloading will be lower than with other methods. Cars will usually be released more promptly and switch engine service reduced.

The metallurgical advantages are largely the direct and indirect results of the following:

1. Extreme accuracy and uniformity in the composition and physical character of the charge.
2. Thorough and intimate mixture of the charge.
3. Close control of the disposition of material in the charge-car and furnace and uniformity of same practically independent of skill or diligence of operator.

The first of these advantages results from the action of the ore-bedding tripper, which travels on its forward stroke at a speed of 500 ft. per min. and on the return stroke 250 ft. per min. A round trip over a bed 500 ft. long consequently takes three minutes. With ore coming to the bed at the rate of 240 tons per hr., or 8,000 lb. per min., we have 24,000 lb. deposited during each trip. This amounts to 48 lb. per linear foot of bed. Now a given lot will not generally make an even number of layers, so that there will be an overlapping of layers on the bed, and the result will be that any particular linear foot of bed may receive too much or too little to an amount ranging from nothing to 48 lb. The average plus or minus error will thus be 24 lb. on any foot of bed for any one lot. Each foot of bed contains 10,000 lb., so that even if the lot in question were 100% SiO_2 for instance, the error in the percentage of that component would be only 0.06%. These errors are not only small but they are compensating in every sense. They will not conceivably occur constantly in one place in the bed, and if they did, their alternatively plus and minus character would tend to neutralize them. Even if they were all plus or all minus and recurred constantly at the same part of the bed, they would apply to the iron and lime as well as the

silica and the net result would be an infinitesimal variation in the analysis of the bed.

The thorough admixture of the charge results from nature of the bed and the action of the reclaiming machine. The triangular moving harrow on the front of the machine is set at such an angle (adjustable at any time while running), that every lump or particle agitated by it rolls down the slope to the conveyor part of the machine. The machine advances into the bed at the almost imperceptible rate of $\frac{1}{2}$ in. per min., so that at any instant an extremely small quantity is being taken from every part of the cross-section of the bed in an absolutely continuous manner. Everything is combined on the bottom plate of the machine, with no possibility of any preference being given to any portion. If all the lime is at the bottom of the bed, and all the silica at the top, and all the coarse at the edges, the result will not be affected in the slightest degree, for when the machine has advanced a foot or an inch, everything there was in that length of bed will have been removed and mixed.

Of course, the accomplishment of these things is purely relative. They are accomplished to some degree in every smelting plant. In all other methods of handling the charge in practical use today, however, the approach to perfection in these matters is limited at a certain point by absolutely impassable barriers. What is claimed for the method under consideration, is the removal of these barriers, without introducing others, making possible an approach to perfection so close as to promise a remarkable improvement in furnace performance over what is now the best.

Some of the limitations here referred to are:

1. The running out of bins or small storage units.
 2. The variation, chemical or physical, in different parts of the same bin.
 3. The limitations of the usual bedding operations in which the thickness of the layers must be determined by estimation.
 4. The irregular caving of the face of the bed.
 5. The practical limitation of the accuracy of weighing small quantities separately in making up the charge.
 6. The practical limit to the amount of work that can be done in the mixing of the charge and in the placing of it in the furnace or the charge car.
 7. The limit to the uniformity with which workmen can be made to do the above, regardless of the amount of time allowed.
 8. With charge containing material of all sizes, the impossibility of creating a desirable gradation of coarse and fine from the centre to the walls of the furnace without danger of separating one ingredient from another.
- Even if it were not possible to observe the above directly and in detail, the proof of the importance of irregularities resulting from the handling of the charge is forthcoming from the furnace itself. With the same blast, the same water circulation, and regular tapping, a variety of undesirable conditions arise which can be traced only to irregularities in the charge or in the feeding. Sometimes these are more or less directly traceable to wall accretions. But these accretions themselves must generally be due to local or temporary occurrences of abnormal charge which forms a material which prefers to affix itself to the walls of the shaft rather than run out at the tap-hole. The charge is here spoken of as including the fuel, and abnormal charge would in this sense be produced by misplacement of fuel. The shaft accretions or other irregularities of the furnace may at times be traced to abnormal conditions in front of the tuyeres. But all of the tuyeres receive the same blast and if variation in the charge is not causing differences in the crust on the jackets the latter will all be of the

same temperature. Again, we are generally forced to look to the existence of an abnormal charge above the tuyeres, producing material of different fusibility or different temperatures in front of them, in order to explain differences in the conditions at the tuyeres. Of course, leaks or derangement of blast or water supply or tuyeres full of slag are competent to produce irregularity, but these are things which are capable of being almost entirely eliminated.

Even where the slag analysis agrees closely with calculation from the charge, there may be, and probably generally are, parts of the smelting column containing a disadvantageous proportion of silica, lime, fuel, or other ingredient; these parts smelt at the best efficiency they can, while the slags mix in the crucible and in their combined analysis give no clue to the local irregularities within the furnace, due to the imperfection of the mixture.

In short, although the work at any particular plant may be of the highest order, still with the proposed system, the probability is that there will be a radical improvement in furnace speed, a practical elimination of excessive accretions, and a general perfection of metallurgical work hitherto unattainable.

RHODESIAN DEVELOPMENT.—The expansion of the gold industry in Rhodesia to the annual production of \$10,000,000 has been accomplished by the small investor and individual effort rather than by means of capital. Small reefs have been discovered in this territory, and many are confidently predicting that Rhodesia in a few years may perhaps excel the Transvaal in the production of the precious metals. Small operators with little capital by their own efforts have of late been extracting nearly one-third of the total amount of gold found, and their earnings have been spent mostly in the colony, as a consequence of which there has been a revival of trade. Rhodesia's output of minerals other than gold has increased and several new industries have come into life during the year. Pioneer settlers along the Cape to Cairo railroad have proved that what could be done in South Africa could also be done farther north, and some remarkable crops have been grown. The Kafue river, the bridging of which was an engineering feat only second to that accomplished at the Victoria falls, afterward proved to be a useful waterway, for it extends 100 miles, and several steam and sailing crafts have already been put on it. The close of 1906 saw the launching of a great scheme for the supply of electricity for the Rand, and Rhodesia is interested in this from the fact that it is the intention to derive a vast amount of that power from the Victoria falls.

IRON INDUSTRY IN CANADA.—A group of iron manufacturers at Erie, Pa., have established the Manitoba Iron Rolling Mills Co. at Winnipeg, Canada. The mill and the puddling furnace are now in operation, using large quantities of scrap iron. It is the only iron mill in Canada between Port Arthur and the Pacific coast. Another new plant has gone into service at Port Arthur, which is using exclusively Manitoba ore. This mill is paid a bounty of \$2.10 per ton by the Canadian Government. Mills which use American ores receive a bounty of \$1.10 per ton. At the present time the Dominion Government is paying bounties at the rate of nearly \$3,000,000 per year on the production of iron and steel. The total capacity of the Canadian blast-furnaces in the active list is 2,235 tons per day; the capacity of the furnaces now planned or under construction is 1,100 tons per day. There is no plant in Canada yet at which ship-plates and the larger sizes of structural steel are made.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

A conveyance by an owner of land of the undivided half interest of the coal under the land, which was executed after a conveyance of the other half of the coal thereunder, operated as a severance of the coal from the land, so that thereafter the mere possession of the surface did not extend to the possession of the coal; and the holder of the paper title to the coal was entitled to recover in ejectment against the owner of the land, unless the latter and those under whom he claimed title had been in the adverse possession of the coal as such, independent of the possession of the surface, for more than ten years before the beginning of the action.

Gordon v. Park, (Mo.) 100 S. W. 621. (March, '07.)

The liability imposed upon mine owners by the Illinois mining act, of responsibility for the defaults of mine managers and mine examiners, who are required by that act to be selected by the mine owners from those holding licenses issued by the State mining board, created by such act, does not deprive them of their property without due process of law, where it is not obligatory upon any mine owner to select a particular mine examiner, or to retain one after selection, if found to be incompetent.

Wilmington Star Min. Co. v. Fulton, 21 Sup. Ct. 412. (March, '07.)

The statute selecting mine owners as a class upon which to impose liability and responsibility for the defaults of mine managers and mine examiners required to be selected from those holding licenses issued by the State mining board, is not repugnant to the constitution as denying the equal protection of the law.

Wilmington Star Min. Co. v. Fulton, 21 Sup. Ct. 412. (March, '07.)

Where the drilling out of unexploded charges was shown to be highly dangerous, and in the proper conduct of mining should never be done, it was held to be negligence of the company for its superintendent to direct an inexperienced miner, without instruction, to drill out an unexploded charge by reason of which he was injured.

Peters v. George, 154 Fed. 634, May, '07.

A mine owner may adopt a rule prohibiting persons who have left his employ from entering his mine; and such rule is reasonable although adopted for the purpose of keeping striking miners out of the mine, and though it prohibits them from entering the mine for their tools.

Sloss Iron Co. v. Prior (Ala.), 44 So. 649, July, '07.

Mining houses and machinery erected with the intention that they should remain and become a part of the real estate, are fixtures.

Hoye Coal Co. v. Colvin, (Ark.) 104 S. W. 207, July, '07.

Under a statute giving a laborer a lien on an output of a mine and on machinery, tools, and implements used in a mine, a miner employed by a non-resident lessee could not establish a lien against the mine and machinery and tools without proving a valid debt against the lessees.

Hoye Coal Co. v. Colvin, (Ark.) 104 S. W. 207, July, '07.

Where different owners of a mine united in working it without any agreement, the act of working together created a partnership.

Kirchner v. Smith, (W. Va.) 58 So. 614, Feb. '07.

An action for contribution by one partner in a mine for money paid for the partnership in the prosecution of mining may be retained by the court on the docket for further decrees against the defaulting partners.

Kirchner v. Smith, (W. Va.) 58 So. 614, Feb. '07.

Arrangement for Dumping Buckets.

Written for the MINING AND SCIENTIFIC PRESS
By H. N. HERRICK.

The arrangement to be described is similar in principle to that published by Mr. F. S. Beckett in the MINING AND SCIENTIFIC PRESS of October 5. It is a device used

into a bin, whence it is drawn out from time to time by the skips through a convenient chute.

The bucket used is of the usual form, of curved sheet steel, with projecting 1-in. pins riveted to patches near the bottom, and is hung by 12-ft. chains to a crosshead raised on 4 by 6 in. wooden guides by a 15-hp. compressed-air hoist at the station. The chains are only long

Rear Elevation.

Side Elevation.

Arrangement for Dumping Buckets.

at the Standard mine of the Federal Mining & Smelting Co. at Mace, Idaho, for shaft-sinking, and the details of it were worked out by Mr. R. S. Pascoe, superintendent of the Standard. The arrangement is used for hoisting from the bottom to the lowest level, in the compartment used above for pipes and wiring, the regular hoisting compartments being provided with heavy bulkheads to catch droppings from overloaded skips in the usual way. At the station the rock is dumped by the automatic device

enough to let the bucket reach the bottom without danger of getting the crosshead below the timber.

It would seem that a crosshead is absolutely necessary for a device of this sort if it is to be automatic to any degree, as without it the pins on the bucket would never come fair with the catches for dumping, due to the twist of the cable. On account of the use of the crosshead, the curved dumping pieces cannot go out to, and beyond, the line of action of the cable, as in Mr. Beckett's design;

the deflecting guide-pieces shown opposite to them have to be used in this case, to push the bucket enough to keep the pins against the dumping-piece, and to keep the bucket overbalanced toward the bin.

In use, the bucket is raised until the pins on the bucket are heard to drop into the catches on the dumping-piece, when it is lowered and empties into the bin. It is then raised until the spring-latches slide past the pins and backsnap against their stops, when the bucket is again lowered, and the pins slide along the curved upper surfaces of the latches, which prevent their entering the dumping-catches from above.

The pump-man at the station acts as engineer, and the scheme works smoothly and surely, with no attention whatever. I should think that some such spring-latch would be a good addition to Mr. Beckett's arrangement, but I do not know whether it is patented or not. A couple of 60-penny nails, an empty candle box, and a couple of strong rubber bands of the catapult variety should furnish ample materials.

Vanadium in the United States.

Vanadium, one of the rare metals, is used principally for hardening steel, especially in connection with chromium. The addition of a very small quantity of vanadium to chrome steel greatly increases its tensile strength, affording a steel that is much used in the axles and other parts of the higher priced automobiles, as well as for the stronger parts of other machines.

Roscoelite, a vanadium mica, occurs in commercially valuable deposits in southwestern Colorado, where it was mined and reduced in 1906. The ore contains about 2% of the metal. The product, an iron-vanadium compound, is shipped from the reduction plant at Newmire to Niagara Falls, and smelted by electricity to a ferro-vanadium containing about 25% vanadium, and selling for \$5 per pound of the contained vanadium. Another Colorado plant, at Cedar, produces vanadium as a by-product in the concentration of carnotite ores, about 20% of the concentrate being vanadium oxide. Vanadinite and other ores of the metal are found in small quantities in Colorado and Utah, as well as in the Southwestern States.

Vanadium salts are used in medicine, in ink and dye making, in coloring glass, and in chemistry. Vanadic acid is used as a pigment, affording a golden bronze that is very little inferior to true gold bronze.

GEMS IN THE TRANSVAAL.—The diamond industry of the Transvaal is a growing one and depends chiefly upon the Premier diamond mine, which has produced about \$17,500,000 worth of stones since the commencement of operations in December, 1902, and contributes about \$800,000 monthly to the diamond returns. Several diggings on the Vaal river contribute a number of stones during the year, but the river digging output is erratic, and the working population of the alluvial fields varies a great deal. Quite recently some excellent stones have been discovered upon a private farm near the Rhodesian border, and the extent of the alluvial wash at this spot promises well for a future output of excellent quality stones. A few small rubies have been found in gem-bearing washes in the northern Transvaal, but as yet no ruby fields have been made of sufficient importance to warrant throwing open any of the diggings to individual diggers. The diamond output for the year ending June 30, 1906, was 758,406.21 carats, valued at \$1,341,145, of which by far the greater portion was contributed by the Premier company.

The Prospector.

Enquiries sent to this department are answered free of charge, submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

Both specimens sent by E. C. D. M., Pioche, Nev., are Barite, the sulphate of barium.

A specimen of yellow Garnet containing black Hematite was received from D. G., of Terrazas, Mexico.

The rock from C. H. W., of Grizzly Flats, is Diabase. The three specimens sent previously have not been received.

The specimen from Iron Springs, Idaho, marked C. S. McM. are: No. 1, Soapstone; No. 2, Chalcopyrite in a quartz-feldspar rock; No. 3, Quartz with Hematite; No. 4, kaolinized rock; No. 5, Limonite.

The rocks from San Simon, Ariz., marked H. A., are all of the same general type of volcanics, probably rhyolite or quartz-porphry, some of which has been mineralized with pyrite.

From Eckley, Ore., marked E. S. W., come: No. 1, Hornblende and Quartz; No. 2, Chromite; No. 3, silicious Limonite; No. 4, Quartz with Pyrite and Sphalerite; No. 5, metamorphic rock with Pyrite and Calcite; No. 6, Graphite and Pyrite; No. 7, Quartz with Pyrite.

L. I. T., of Gleeson, Ariz., sends: No. 1, rock stained with Cuprite and Malachite; No. 2, altered rock, perhaps a Rhyolite, stained with Hematite; No. 3, rock with red Hematite, formed from the oxidation of the pyrite; No. 5, cherty Rhyolite with Hematite.

DIAMONDS IN NEW SOUTH WALES.—The more recent and more important diamond districts around Bingara and Inverell are situated near the Queensland border. Bingara is 378 miles north of Sydney, and Inverell and Tingha are both nearly 40 miles east of Bingara. The divisions named from the two latter places contain much tin in the drift, while the Bingara division is worked principally for gold. With regard to diamonds in particular near Copeton, in the Inverell district, are numerous isolated hills capped with basalt, beneath which are sands and gravels, with tin, diamonds, and some gold. These hills have been variously named, one of them being the celebrated diamond locality of Boggy Camp. It was in this district that the discovery of two small diamonds in a basaltic dike was made in 1904, at Oakley creek, near Copeton. The Bingara division presents conditions somewhat similar, yet with some differences. The chief diamond yield has been from patches of gravel capping the foothills of the basalt covered range some five miles to the southwest of Bingara. It is in the Bingara district, at Ruby hill, that the eclogite-bearing pipe was observed in 1902, which led to so much discussion as to eclogite being the probable source of the diamonds. There has been but little activity of late in these fields owing to low prices for the diamonds, which are all of small size.

TRANSVAAL COAL.—The Transvaal is exceptionally fortunate in having large supplies of easily worked medium quality coal, which can be delivered at the mines in bulk, and is one of the most important features in cheapening the cost of working the low-grade ores of the Witwatersrand.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

MAGNETIC SEPARATOR.—No. 867,744; James B. McCabe, Buffalo, New York.

A magnetic separator comprising a drum having inner and outer magnetic surfaces adapted to serve independently in the separation of magnetic from non-magnetic particles, and means for detaching the magnetic particles from said surfaces.

DREDGING-MACHINE.—No. 867,788; George M. Brown, Tacoma, Washington.

In an apparatus of the character described, the combination with a floating structure, of a rotary cutter-head at one end of said structure, the diameter of said cutter-head being greater than the width or draft of the structure, and an adjustable hood supported above the cutter-head.

MELTING-FURNACE.—No. 867,781; Thomas D. Bausher, Reading, Pennsylvania.

In a knock down melting-furnace, a rectangular body comprising four vertical walls, each of which is formed with interlocking hinge members, pins for securing together said members, a removable floor, a door in each of said wall members in line with said floor, two oppositely disposed, horizontally sliding dampers, said dampers having their inner edges concave and provided with handles at their outer ends, a movable supporting rod and a melting pot supported by said rod and depending below the line of said dampers.

SYSTEM FOR VENTILATING MINES, ETC.—No. 867,791; George M. Capell, Passenheim, England.

In a system for ventilating mines, etc., the combination of two air drifts leading from the mine, a fan connected to each of said drifts, and a main passage-way connected to and between said drifts for equalizing the pressure of air within said drifts.

CENTRIFUGAL FAN AND PUMP-WHEEL.—No. 867,874; George M. Capell, near Stony Stratford, England.

A centrifugal wheel for circulating fluids, having a series of vanes extending inwardly from the periphery and blades back of the vanes, each such blade extending inwardly toward its vane and at a greater angle from the radius than such vane, said wheel having an opening at or near the inner end of the blade leading into the space between the blade and vane.

HYDRAULIC CLASSIFIER FOR ORES.—No. 866,536; Seth R. Swain, Denver, Colorado.

The combination with a trough having a pocket therein, a fixed and movable baffle board in said pocket, the latter movable bodily to one side, means for adjusting the movable baffle board, and a screen extending from one end of the pocket to the fixed baffle board.

DUMPING-CAR.—No. 867,726; Maurice P. Henvis and Daniel S. Clark, Norfolk, Virginia.

A dump car comprising a braced frame, hoppers supported by said frame, said hoppers having curved ends, and sliding bottom extensions to said hoppers. A dump car comprising a frame, of hoppers pivoted to said frame, a bottom for said hoppers having a sliding extension thereto.

A Centrifugal Roller Quartz Mill with Central Feed.

The patentee, L. C. Graupner, was formerly engaged in selling Huntington mills, and during a period of 15 years he had his attention called to the defects of these mills as then made, and this led him to invent the improvements noted herewith.

The machine has a central feed which discharges the ore through four openings (in the central cone) to be evenly distributed by the scrapers, so that the rollers will crush an equal amount of ore at all parts of the die-ring, thereby increasing the capacity of the mill and insuring an equal amount of wear around the entire face of the die.

The die-ring sets into the pan without the use of wooden wedges. In this mill the die-ring is tapered, and is fitted into the pan, the wall of which has an equal taper, so that when the ring is driven down to place, the die and pan bottom are as one piece, which forms a solid anvil for the rolls to crush against, and permits wearing the die down very thin so that little of the steel is lost or need to be thrown away. The die is easily set and always comes to a perfect centre.

Roller rings are secured to the roller-head without the

on the bottom edge has a tongue which fits into a groove in the pan bottom, so that only a small packing is required in the bottom of the groove to make the joint perfectly water-tight.

Commercial Paragraphs.

THE AMERICAN LOCOMOTIVE WORKS, of New York, report the following orders: Two standard gauge 6-wheel tank engines for the Fo-Kien Ry. Co. of China; one compound steam-motor car for the Chicago, Rock Island & Pacific Ry.; 125 locomotives for the Harriman lines, made up as follows: 30 Mogul type, 10 Atlantic type, 43 Consolidation type, 24 10-wheel type, and 18 6-wheel switching locomotives.

THE DENVER ENGINEERING WORKS CO. is preparing to ship what is believed to be the largest electric mining-hoist ever made for installation in the United States. This machine will be installed by the Nevada Con. Copper Co. at Ely, Nevada. The hoist will weigh, without electric apparatus, 55 tons, and the electric apparatus will weigh approximately 20 tons. It will require five cars to make the shipment. Round rope will be used on the drums. The machine is of the double-drum type. Another machine of

use of wedges. In this mill the rings are tapered on the inner side, from the centre to the edges, and are securely held in place between the roller-head and its follow-ring, making it impossible for the ring to become loose, and permitting the wearing of the ring to a thin shell, thus saving steel and also delivering the full force during the entire life of the rings. The rings are easily and quickly changed and will come to a perfect centre as the bolts are screwed down. The removable splash-ring can be replaced when worn out, thus avoiding the throwing away of the entire housing when the splash-curb is worn away. The removing of the splash-ring also leaves more room in the mill when cleaning up or making repairs.

The main driving gear rests upon a large ball-bearing, having balls $1\frac{1}{2}$ in. diam. and race-rings of large diameter, distributing the weight of the gear around the central cone, to which the race-rings are secured. This ball-bearing takes the place of the old-time central shaft, its heavy bearings and large driving pulley. The pulley frame has a small tight and loose pulley for driving the mill and ore-feeder, which requires only a four-inch belt to drive the largest mill. The pulley-frame is so arranged that it can be removed and a pedestal put in its place to receive an electric motor for direct connection.

The mill is so arranged that all the working parts, together with the splash-ring, can be hoisted out of the pan and housing without the loosening of any bolts or other parts, thus enabling the operator to clean up the mill in the shortest possible length of time. The mercury well is placed so that there is no projection below the bottom of the mill, leaving the bottom smooth so that rollers can be used in moving the mill to position and the mill will set fairly on a smooth foundation. The housing is cast in one piece, and

the same size will be ready for shipment in about three weeks to another mine in the Ely district.

THE KELLY FILTER PRESS CO., of Salt Lake, owning the patents on the Kelly filter-press, are installing one of their 50-ton units in the cyanide plant at Pearl, Idaho. This is the second 50-ton unit of this type they have installed during the past few months. One of their machines is in use at Cripple Creek, Colorado. Their catalogue, which describes the machine fully, is ready for distribution and will be mailed upon request.

THE A. S. CAMERON STEAM PUMP WORKS, of New York, are using their Slogan with such good effect in their advertising literature and trade paper publicity, that it long ago became well known to the trade and to users generally. This company also adopted the motto, "Character; The Grandest Thing," because it was the character of their product that made the Cameron reputation. This principle is embodied in the manufacture of every pump that is produced from their works. All Cameron pumps are marked with the Cameron symbol and trade mark: The Acorn.

Catalogues Received.

'Report of the Department of Mines, West Australia, for the year 1906,' Government Printer, Perth, West Australia.

'Papers and Reports Relating to Minerals and Mining,' Government Printer, Wellington, New Zealand.

The Clason Map Co., of Denver, send a copy of their new map of the Bullfrog district. Retail price, 50 cents.

We have received from the United States Geological Survey 'Bulletin No. 313; The Granites of Maine,' by T. Nelson Dale.

Editorial.

WE ARE GLAD to note that both the Allis Chalmers Company and the Westinghouse Electric & Manufacturing Company have been able to give reassuring statements concerning their affairs. The former reports a considerable gain in profits and the proximate completion of important enlargements in its manufacturing plant, while the Westinghouse company, although temporarily operated under a receivership, is in a position to fill orders and to conduct business as usual.

IT IS RUMORED circumstantially that the Amalgamated people have obtained control of the American Smelting & Refining Company, owing to financial difficulties in which the Guggenheims have become involved. We hope this proves to be untrue. The Guggenheims are not philanthropists exactly but they are much to be preferred to the predatory financiers of the Amalgamated and Standard Oil companies. Besides, the Standard Oil group controls enough; any extension of their power over the mining industry would be highly detrimental.

A RECENT QUERY in regard to the making of a dam with slag has elicited a most valuable bit of information from Mr. Hiram W. Hixon, the metallurgist responsible for the dam at East Helena. Mr. Hixon is now manager of an important smelter in Canada, but he has left an enduring monument to his ingenuity in the shape of the slag-dam in Montana. He is a keen disputant in matters relating to ore deposits, and it is fair to say that if he knows as much about igneous processes in the past as he does concerning those controlled by man, his views on a burning question must be received as authoritative.

ON ANOTHER PAGE we publish the advice given by Mr. Courtenay De Kalb on the occasion of a recent informal address to the senior class in the College of Mining at the University of California. While intended for the inexperienced, it will also interest those who have served their apprenticeship, for it will recall some of their own troubles, blunders, and successes. It is based on the facts of life at the mine and mill, and for that reason it bites into the intelligence of the reader, as it did into the alert minds of those that were listeners. We direct attention to a lucidity of statement and a manner of expression that mark the scholar and the scientist; Mr. De Kalb speaks in terms that fit and in similes that illuminate. As for the matter, comment is supererogatory. One point only we venture to emphasize, and that is the advice to pay attention, first and foremost, to the mine itself, as distinguished from the administration at surface and the work of the mill. The American mining engineer is especially capable as a

mill manager, as an administrator of business affairs, and as a mechanical engineer; when he fails, it is usually in the actual work of mining, that is, finding ore and extracting it cheaply. That part of his duties is left too much to the supervision of Irish shift-bosses, Cornish foremen, and intelligent Finns. Directors of mining companies and mine operators in general are unable to recognize good or bad underground management, while they do appreciate nice maps, a beautiful mill, systematic accounts, etc. And yet it is underground that a mine is made or marred. Apart from the cost of breaking ore and sending it to surface, the finding of new orebodies or the care not to lose the traces of those already discovered is a decisive factor in making a mine successful. To do this, there is only one way and that is to go underground and become familiar with the workings, the characteristics of the deposits, and the conditions that affect the distribution of ore in the rock. To be a miner, go underground.

THERE MUST be many places where jigging by hand can be applied profitably, especially in the more remote parts of Mexico. Mr. Arthur C. Nahl's description of the jigs designed by him at Triunfo will be useful to many superintendents of mines. For it happens often that the amount of ore suitable for jigging, say, in an old dump, will not justify the investment of capital in expensive machinery, while it will warrant such an apparatus as is described elsewhere in this issue. Such machines can be made by a company and distributed to the tributers or *gambucinos* on a royalty, with results profitable to all concerned. It is likely that among the abandoned mines or *antiguas* of Mexico, there are dumps capable of yielding a profit if jigged by hand, while the old workings are being re-opened.

On the Margin.

AMONG the after-effects of the recent collapse of credit at New York and Pittsburg, there has been a sort of house-cleaning on the part of the exchanges and banks. Certain undesirables have been practically driven out of business and the force of public opinion has been recognized to such an extent that the gamblers have promised to reform. It is interesting to read that during this convalescence of a sickly credit system the banks "frown upon marginal operations in stocks" and a hint to that effect "has been conveyed to stockbrokers in terms not to be misunderstood." This brings forward a subject concerning which we hold a decided opinion, and it is an opinion shared by many others capable of viewing speculation in stocks with some degree of mental detachment. Why should trading on a margin be permitted at any time? Why should the banking authorities "frown" upon the practice only at a time like this? Is it only theorists and dreamers that consider it wrong to sell what you do not own and buy what you have not money enough to pay for? A man puts up a margin of 20 per cent and sells your stock, expecting that you will have to sell it for a lower price, or he buys your stock in the expectation that you will be glad to dispose of it on a ris-

ing market to some third person. As a matter of fact if you sit tight, his operations will not affect you, and it is mainly another gambler betting on the opposite side that contributes the other side of the game. For a game it is—not business nor industry—no better essentially than betting on horses or cards or the black and red. And is it anybody's business whether these gamblers bet on stocks or on cards? Yes. Because by their reference to the property of other people as an excuse for their betting, they disturb the valuation of such property. You want to sell your stock to get money for a business enterprise and you find that it is quoted much lower than when you purchased it, not because the earnings have decreased, but merely because one gambler or set of gamblers has been betting that it will go down and has got the best of the other fellow or the other clique, who were betting that it would go up. You want to invest your savings and you turn to railroad stocks or mining shares as quoted on the Exchange, the legitimate office of which is to afford facilities for the 'exchange' of property in money, stocks, and bonds. You find that you cannot get a safe investment except at a preposterous price, yielding an extremely low rate of interest. Why? Because the gamblers have been playing with the stock and others like it, so that it has been given a fictitious value, which is usually too high, because the professionals make their money by selling—to the public. If trading on a margin were prohibited, all the active stocks would drop 20 to 35 per cent even below their present low prices, and the result would be that the actual investor—everyone and anyone except those who make money by betting on the fluctuations—would be able to get securities yielding him 8 to 12 per cent, instead of the usual 4 to 5 per cent obtainable on first-class stocks at the usual inflated prices. Here in San Francisco during the days of the Comstock, the servant girls and cooks who "played the stock market" were called 'mud hens' because they dabbled on the margin. To us the gentlemen on whom the banks, for a few minutes, are "frowning" might well be called *zapilotes*.

Copper Statistics.

"THERE are three kinds of lies: lies, damned lies, and statistics." So said Disraeli. We concur. And statistics are particularly likely to mislead when they are taken too seriously. Thus our contemporary at New York falls foul of the Geological Survey and points cheerfully to a serious error made in the statistics of copper as published by the bureau at Washington. The geologist in charge of copper statistics is, we understand, perfectly frank in acknowledging that he made a mistake in the output of Montana in 1906, the error arising through the neglect to include the copper produced at the Montana Ore Purchasing Co.'s works in the early part of the year and before that smelter was dismantled. Thus some 7,000,000 pounds of copper were overlooked. Meanwhile, the editor at New York, who is not unwilling to criticize the geologist at Washington, made an error in the Michigan figures, for he got his data from the State Commissioner of Mineral Statistics, who keeps

account of the copper in the ore produced at the mines. Mr. L. C. Graton of the Survey got the figures of copper actually smelted, and as the high price for the metal caused the smelters to use up old stocks of ore, his total for Michigan is higher than that of Mr. W. R. Ingalls, and more correct by just the difference, namely, 5,000,000 pounds. Finally, as regards the production of California, both statisticians were in error by about 4,000,000 pounds of copper, for both omitted to include the yield of three large mines, which contributed during 1906, and were overlooked because they were in separate districts not usually productive of copper.

It appears also that while one authority estimates that the rate of increase last year was 2.03 per cent, the other makes it 4.08, and we confess to believing that whichever

it be dubbed the science of the inexact. "You can prove almost anything by statistics"—so says the proverb—especially their inaccuracy.

Gold and Silver Production in the United States in 1906.

BY COURTESY of the Acting Director of the Mint, we are in receipt of the revised figures for the estimated production of the precious metals in the United States during the calendar year 1906. The total gold yield is estimated at \$94,373,800 as against \$96,101,400—the provisional estimate given out in January. At that time Nevada was credited with \$9,815,800; now it is put down for \$9,278,600. Arizona is estimated at \$500,000

is right this year is likely to be wrong next year—which sounds ungenerous, but we mean that the tabulation of outputs is based upon compilations and outputs, the accuracy of which is never certain, simply because it comes at second-hand and from people often unwilling to be exact. We have knowledge of important data being given with the intention to mislead; they did not refer to copper, but they affected a total quite as impressive as the total production of that metal. To be a successful statistician requires the skill of a detective and luck, and then more luck. Therefore the public should not take statistics, nor statisticians, themselves, too seriously. They—the statistics, not the statisticians—are useful approximations, if timely, but only imposing inanities if overdue by a year or so, as has happened both at Washington and New York. On the other hand the statisticians—not the statistics—happen in this case to be men of unusual ability in other directions, in which their work is of special value. The training and experience of two gifted scientific men are diverted to a subject that by no stretch of imagination can be termed a science, except

less and the California figures are \$200,000 more. The silver statistics are practically unchanged as to the total, the difference being only 334,400 ounces more, but Montana is increased nearly a million ounces, and Colorado is credited with 200,000 ounces more, so that Montana now leads with a handsome margin. These comparisons simply indicate the difficulty of getting exact data and the chance of errors due to the complexity of the metallurgical operations, by which an ore is mined in one State, smelted to matte in another, reduced to metal in a third, and refined in a fourth. Eternal vigilance is the price of safety in statistical, as in other, work. The Mint figures show that Colorado leads the States in the production of the precious metals, with Alaska second. In gold production Colorado is first, with Alaska gaining every year, so that their relative positions are likely soon to be reversed. In silver Colorado, Montana, and Utah are now nearly equal, the first having lost the unquestioned leadership of the past twenty years. Other interesting features of the tabulated statement will suggest themselves to anyone willing to study the figures.

Personal.

JAMES W. NEILL is in Arizona.
 W. C. RALSTON is at Washington.
 GEORGE W. MAYNARD is at Tucson.
 A. S. DWIGHT was at Cananea lately.
 THOS. J. BARBOUR has gone to New York.
 J. H. WEDDLE has returned from Honduras.
 RICHARD A. PARKER is at Silverton, Colorado.
 THOS. H. LEGGETT is on his way to New York.
 WILLIAM McM. HUFF is assayer at Kellogg, Idaho.
 MAX BOEHMER, of Leadville, is at Goldfield, Nevada.
 W. SPENCER HUTCHINSON, of Boston, has been at Butte lately.

PATRICK HOLLAND was in town from the Trinity county mines.

W. A. FARISH has been examining mines near Ely, Nevada.

A. E. BIDLAKE has left England to go to Erithrea, in Abyssinia.

CARL O. LINDBERG is at Mexico City, with CARPENTER & BRENNON.

ALGERNON DEL MAR has left Colorado and is now at Pasadena, California.

EDWARD H. BENJAMIN is directing dredging operations in Sacramento county.

EDWIN T. FIELD, manager of the United Elkhorn mines in Oregon, is at Chicago.

L. A. WOMBLE leaves San Francisco this week for Colombia, South America.

C. A. RICE is superintendent for the Providence Mining Co., at Webb City, Missouri.

J. MORGAN CLEMENTS is examining the Gold King mines at Silverton, Colorado.

THOS. A. VARDEN, of Sacramento, Cal., has been at Goldfield during the past week.

T. S. RODGERS, of Los Angeles, has returned from examining mines near Salome, in Arizona.

EMERSON GEE has returned to Reno, Nev., from examining gold mines in Sierra county, California.

ROBERT D. LUCE has been appointed superintendent of the Castle Dome mines, in Yuma county, Arizona.

E. H. GARTHWAITE gave an address on 'Rhodesia' to the mining students of the University of California.

S. W. MUDD has returned to Los Angeles from the Ray mine, in Arizona, of which he is consulting engineer.

A. R. PARSONS, superintendent of the Tonopah Mining Co.'s mill, has returned to Millers, Nevada, from a visit to Salt Lake.

JOHN B. GAFFEY, lately with the Bulaklala Co. at Coram, Cal., has accepted a position with the Oregon Smelting & Refinery Company.

E. F. LINES, of the U. S. Geological Survey, is spending the winter at Urbana, Illinois, in studying the clays of the coal measures in co-operation with the State Geological Survey.

G. H. ASHLEY, DAVID WHITE, and F. W. DEWOLF have been making a trip through the coalfields of Illinois, Indiana, and western Kentucky for the purpose of studying the correlation of the various coal beds.

G. S. RICE, for many years connected with the Colorado Fuel & Iron Co., the White Breast Fuel Co., and other coal mining companies, has arranged to devote his whole time to consulting work and has opened an office in the First National Bank Bdg., Chicago.

CLYDE T. GRISWOLD has entered upon his duties as professor of mining and metallurgy in Colorado College, Colorado Springs. Mr. Griswold is a graduate of Amherst College and of Columbia University, and was connected for some time with the Canadian Copper Co. as superintendent of their Crean Hill mine in Ontario.

General Mining News.

ARIZONA.

COCHISE COUNTY.

The Sacramento shaft of the Copper Queen is sunk to a depth of 1,200 ft. A drift is being driven from the Lowell shaft to connect with it at that depth. The Sacramento shaft will probably be the main hoisting shaft in the near future. A new power-house is being built at this shaft. No further reduction in the force at the Copper Queen mine is expected.—Considerable prospecting and development work is being done at the Calumet & Arizona and the Superior & Pittsburg properties.—The Shattuck is shipping 200 tons of sulphide ore to the Globe smelter. The oxidized ore is being piled on the dump owing to the refusal of the Copper Queen smelter to accept it. The orebody on the 600-ft. level is looking well.—The Denn-Arizona has stopped shipping but is developing the orebody on the 1,100-ft. level.—At present there is considerable mining activity in the Dragoon Mtn., north of Tucson, where many copper prospects are being developed with favorable results.

GILA COUNTY.

The Old Dominion company no longer works its mines Sundays and it is probable that the other companies at Globe will adopt the same policy. A week ago last Sunday the Dominion smelter made a record run when 770 bars of blister copper were turned out.—The Gibson mine on Pinto creek is still working 200 men; most of the development work is confined to the three-compartment shaft. This mine ships about 1,200 tons per month.—The two-compartment shaft at the Powers Gulch group on Pinto creek is down 69 ft. and will be continued to a depth of 250 ft.—A contract for a 300-ft. adit on the Grandstaff group has been let and the work is now progressing rapidly.—At the Arizona National mine development is being confined to the 125-ft. level in order to determine the strike of the big vein which was cut in the shaft at that level. The cross-cut adit is now 180 ft. long.—A flow of water has been struck in a drift on the 360-ft. level of the Calumet & Globe and it is thought that a pump will have to be installed to handle this flow. The Central and Union mines on upper Pinto creek have shut down.—The Gem shaft of the Globe Con. has reached a depth of 1,075 ft., but is to be sunk 125 ft. deeper before cross-cutting.—The Superior & Boston is actively developing its property. The mine is looking well.—Sinking has been resumed at the B shaft of the Old Dominion Co.; the C shaft is to be sunk another 200 ft. All the ground above the 9th level has been drained by the drift from A shaft on the 10th level so that water will not interfere much with this sinking. The winze from the 14th to the 16th level has been completed. The station on the 16th level is being cut. The A shaft is now 1,235 ft. deep.

GRAHAM COUNTY.

At the time that the slump in copper began, about 4,500 miners were employed in the Clifton-Morenci district; according to Clifton papers only about 500 men had been laid off up to last week.—Work has begun at the Bonita group in Lone Star district. Four teams are hauling machinery to the mine. Fifteen men are working at the property.—A 5-stamp mill will be erected at the Gold Belt group as soon as sufficient treasury stock can be sold to pay for it. The mine is looking well and considerable ore is on the dump.—The vein at the Buzzard Shadow claim of the New York-Arizona Co. appears to be widening, but as yet a depth of only about 20 ft. has been reached. At surface the vein was 12 in. wide, at 18 ft. it is 6 ft. wide.

MOHAVE COUNTY.

Considerable development work is planned for the P. K. and K. P. mines in I X L basin, belonging to the Arizona Lead Silver Co. The shaft will be sunk deeper and a cross-cut driven through the vein. At present the cross-cut is 60 ft. into the vein with no sign of the other wall. The lode is well mineralized and carries fair values in silver and lead. H. M. Bowen is manager.—Considerable machin-

ery is to be installed this winter at the placer mines near Temple Bar.—Work at the Idaho mine at Cerbat is progressing nicely. The roaster will soon be ready for running.

PIMA COUNTY.

The Miner Hill Co. has closed down its property near Tucson. Owing to the price of copper, the force at the Silver Bell mine has been reduced.

PINAL COUNTY.

A good vein of copper has been found on the 185-ft. level of No. 2 claim of the Sultana-Arizona Co. near Kelvin. The main shaft of the Sultana is now 65 ft. deep, a two-compartment shaft is being sunk on another one of the company's claims.

CALIFORNIA.

BUTTE COUNTY.

The labor conditions at Oroville remain practically the same as last week, except that the union now has 200 members. No demands have been made as yet for an increase in wages. The men claim that they are forced to ask for higher wages owing to the fact that while the cost of food and rents have increased steadily during the last few years, their wages have been the same for the last six years or more. The dredge companies all assert that they will not grant any raise if it is asked. The Leggett dredge has been paying the winchmen \$3.50 and the oilers \$3 per day for several months. As there are nine men to a dredge the increase of 50 cents to each will only amount to about \$1,600 a year.—Preparations are being made to resume work at the old Cherokee hydraulic mine on Sugar Loaf Mtn., where new pay gravel was discovered last winter. This summer several hundred feet of 14-in. pipe has been laid to bring water to the mine.—Several small veins of chrysophase, a semi-precious form of chalcedony, have been found near Oroville. These veins occur in granite.

CALAVERAS COUNTY.

Active work has begun on the North Star gravel mine. The mine is opened by an 1,800-ft. double-track drain adit. This cuts the channel at the lowest point in the company's property. The North Star company owns 3½ miles along the channel which is practically virgin ground. A large force of men is employed at the mine; L. Everett is superintendent.—Good ore has been found at the Gwin mine in the new drift on the 2,600-ft. level at a point about 400 ft. from the shaft; the vein is 50 ft. wide at that point.

ELDORADO COUNTY.

Good pay gravel has been found at the drift mine of the Prevolcanic Channel company, 18 miles east of Placerville. The channel already has been cross-cut for 20 feet.

INYO COUNTY.

A good strike of ore is reported in the tunnel of the True Fissure mine.

(Special Correspondence).—The past few weeks has seen a great deal of development work on the various lead-silver prospects and mines in this district.—J. P. Fitting, who is developing a property in the Saline valley has struck a large body of rich galena ore which runs also well in silver.—G. W. Oberholtzer, who is associated with E. W. Smith of Tonopah and L. S. Bishop of Big Pine, reports a promising strike of lead ore in some claims that he has located about one mile east of the Bunker Hill property. He will start further development work in the near future.—Eastern parties have taken a bond on the copper property belonging to J. S. Simmonson. This property adjoins Joe Wright's copper claims which are opened up by a tunnel 50 ft. long, the entire face showing an average of 6½% copper with some gold and silver values; the ore is oxidized. Mr. Wright expects to do further development work this fall and winter. These properties are situated at the head of Mazourka canyon and about 13 miles northeast of Independence in the west slope of the White Mountains.—The Montezuma Extension Mining & Milling Co., with G. M. McCollough as manager, is now working in silver ore which assays about 254 oz. in silver to the ton.—W. H. Uhlmeier is working his property four miles southeast of this place and reports that he has found some very good

ore. He has been driving a tunnel and is in about 50 ft. and will start to cross-cut from that point.

Big Pine, Oct. 27.

MONO COUNTY.

The demands for shorter hours at Bodie have been withdrawn by the union as a result of the report of the arbitration committee which found upon investigation that the profit at the Standard mine did not warrant a shortening of hours.

NAPA COUNTY.

The Aetna quicksilver mine has been bonded by a New York syndicate.

NEVADA COUNTY.

A discovery of gold-bearing galena ore has been reported near Bowman's dam, 35 miles northeast of Nevada City. —Nevada county is being flooded with miners from the copper camps of the West; many have been put to work but a good many are waiting for jobs. Globe, Arizona, has furnished the greatest number of these miners. —A good body of rich ore has been found in the recently reopened Golden Gate mine. —At the Yuba mine near Maybert, 28 miles northeast of Nevada City, the east vein has been found after a long search within 40 ft. of the drain tunnel in a cross-cut run from it by the present company. This cuts the vein at a depth of 1,200 ft; the orebody is 3 ft. wide. It is expected that the 20-stamp mill will be crushing steadily by Christmas.

The Greenhorn property is being tested by drills to see whether it will pay to dredge the gravel and old hydraulic tailings left on it. —Grading has begun for a 5-stamp mill which is to treat ore from the Austin mine at Willow creek. A new pump has been installed at the mine. On the 400-ft. level drifts are being run both north and south on the vein. The mine is looking well. —Another rich strike of ore has been made at the Kenosha on the 300-ft. level. When the shaft was flooded the last blast had just broken into a body of good ore on the 400-ft. level. The water-level is being rapidly lowered and every one is anxious to get a view of what the last blast on the 400-ft. level had disclosed. —Extensive improvements are to be made at the Grey Eagle, near Maybert. A hoisting plant will be installed at the end of the long tunnel and the pay-shoot followed below the adit-level. New concentrators will be added to the 10-stamp mill. —The new 5-stamp mill at the Marcotte mine is running satisfactorily.

PLACER COUNTY.

The Crater mine in the Ophir district has been pumped out to a depth of 800 ft. This old mine will now be thoroughly prospected. —The Malmberg 5-stamp mill in Auburn ravine is running on custom rock from the Boulder mine. —Considerable development work is being done at the Paragon mine where they think they have found the upper lead. —The new boiler at the Slope mine is in place and the pumping is progressing again. About 40 men are working at the Slope and the Buckeye mines. —The Dairy Farm mine has been shut down by the Guggenheims until they have made a definite decision in regard to the building of a smelter at South San Francisco. —H. M. Jarvis, representing an Alabama company, has bought the Hosmer claim adjoining the Grey Eagle on the east and south. He has also bought the Owl Creek ditch and will extend it down the North Fork slope and there generate electricity for working the Grey Eagle. The Grey Eagle tunnel will soon be reopened and retimbered.

SHASTA COUNTY.

(Special Correspondence). —The slump in the price of copper has not affected Shasta county mines to any great extent. Even the suspension of construction work at the Balaklala smelter took place some time ago and is due mainly to the negotiations pending. It is believed that the bondholders are trying to get control. In the meanwhile, work at the Balaklala and Shasta King mines has been discontinued, enough ore having been opened up. —The manager of the Mammoth Copper Co. states that the company will continue to operate the mine and continue work on repairs at the smelter. The Mammoth company employs about 1,200 men in the mines and at the

plant. The management further states that the ores of the Mammoth contain enough gold to make the smelting of 4% copper profitable. —The Mountain Copper smelter at Keswick is still operating, and development is continuing as formerly at the mines. —The Great Western Co., operating the Afterthought mine and Ingot smelter, is working on the old scale, and does not expect to curtail the operating expenses on account of the low price of copper. —Large reserves of ore are blocked out in the lower levels of the Gladstone, but extensive development is still being done. —At the Yankee John the shaft is down 100 ft. and a large quantity of ore running \$30 per ton is being developed. A rich strike was recently made near the bottom of the shaft. Anson B. McMay is superintendent. —Some excellent ore is being developed in the Rattler, and large quantities have been shipped to the Mammoth smelter for

Map of California.

fluxing purposes. —Developments at the Mountain Monarch are steadily progressing, and some good ore has been blocked out. —At the Delta Consolidated considerable development is under way in the upper levels, and some promising ore has been exposed. —The main shaft of the Gold Leaf has attained a depth of 170 ft. and ore is being shipped from the 7-ft. vein to the Keswick smelter. Extensive driving is being done. H. O. Cummings is the superintendent. —An immense quantity of ore is blocked out in the Hornet mine, while systematic development is opening up a large area of virgin territory. —The Guggenheims have commenced the shipment of 1,000 tons of copper ore from the Golinsky mine to Kennett. From that point it will be transported to one of the smelters controlled by the Guggenheim interests. The ore has been extracted while doing development work under the terms of the bond. —The 3-ft. vein of rich gold ore, recently struck at a depth of 185 ft. in the White Oaks mine, is improving with development. H. O. Cummings, superintendent of the Gold Leaf, is in charge of the White Oaks.

Redding, Oct. 26.

Work has been resumed at the Golden Leaf mine in Lower Spring district; this mine has been shut down for about a month. Work will soon begin on the electric road which is to extend from the mine to the Southern Pacific tracks near Middle Creek station.

Work at the Keswick smelter has not been affected by the slump in the price of copper, and still is running full force. The ore carries gold and silver, which helps out

greatly when copper is low in price.—A new transformer is being put in at Heroult, and the company hopes to be making ferro-silicon in another week.—As their bond on the Golinsky group, at Kennett, will expire in December, the Guggenheims are going to ship copper ore from that mine to some of their other smelters.

IDAHO.

SHOSHONE COUNTY.

(Special Correspondence).—The closing down of the Wallace Stock Exchange and the failure to pay a dividend by the Snowstorm Mining Co. were the two leading features of last week's developments in the Cœur d'Alene. The closing down of the Stock Exchange has been a matter for little regret in the district and the influence of the local market as well as the Spokane Exchange is considered to have been anything but beneficial to the mining industry of this region. Wash sales and selling short were the direct cause of the death of the institution and, while an attempt to prevent these was made both at Spokane and Wallace, the new conditions came too late to revive public confidence in the market.—The failure of the Snowstorm company to pay a dividend has also had a most depressing influence when, coupled with the reduction of \$60,000 in the monthly dividend of the Bunker Hill & Sullivan Co., it is considered that the Snowstorm company has always proved a key to the whole industry in this quarter. Inability of the smelters to handle the ore and the low price of copper are the reasons given for the passing of the dividend. The mine at the same time continues to employ much the same number of men as formerly and about 100 tons of second-class ore are being treated by the mill. The new bunkhouses erected by the company at a cost of \$50,000, with accommodation for a force of 250 men, were completed and occupied today.—Work has been resumed in the Copper Queen mine at Mullan and a splendid showing of chalcopryite ore has been made. So far the vein has not been fully cross-cut, but already it shows 10 in. of solid 30% chalcopryite and about 5 ft. of high-grade concentrating ore. The strike on this property is a most important one, as the mine adjoins the Reindeer on the east and covers the same lode.—A new company, known as the Shoshone Concentrating Co., has been formed for the purpose of working over the tailing of the Last Chance mine at Wardner. The tailing dump is estimated at 1,600,000 tons. The directors of the new company are M. C. Murphy, Julius Zittel, and William A. Bradley. A 300-ton mill will be erected at once and it is estimated that a profit of about \$1 per ton will be made on the entire mass.—The mill of the Success mine, one of the regular dividend-payers, has resumed after having been shut down for about three weeks to permit of the installation of new jigs, rolls, and vanners. With the new complement of machinery the capacity of the mill will be about 1,500 tons of dry concentrate per month and about two-thirds of this product is zinc concentrate. A new \$10,000 bunk and boarding-house to accommodate 100 men is nearing completion.—O. H. Linn, superintendent of the Success mine, has taken a contract from the Buffalo Co. to drive a 3,000-ft. cross-cut adit on that property. The consideration will be entirely in treasury stock. The necessary surveys for the adit, and also for a flume or pipe-line to develop water-power, is being made at present. A compressor will be installed at once and buildings to accommodate 10 men constructed. The adit will develop two veins that traverse the company's property, giving a depth of 500 ft. on the first, which is a copper vein, and about 2,000 ft. on the second, which is a galena vein. The veins are about 1,500 ft. apart.—The owners of the Pilot mine, at Murray, from which the highest grade gold ore ever found in the Cœur d'Alene has been taken, are now running a lower adit to tap the ore-shoot in depth. This adit has now been driven about 50 ft., but it will have to be driven fully a distance of 150 ft. more before the vein is reached. From this point it will be extended as a drift 500 ft. to get under the ore-shoot in the upper adit.—The capital of the Gertie Co. is to be increased from \$100,000 to \$150,000 in shares of the par value of 10 cents. The increase is due to the fact that the company's stock is non-assessable and there is only a

small amount of the treasury stock now on hand. A force of five men will be kept at work at the mine throughout the winter.—Steady shipments of ore are being made by the Monitor mine at Saltese, Mont., and the main shaft on the property is being sunk to the 500-ft. level and the work of driving on the 400-ft. level is making good headway. Some excellent ore has already been encountered on the 400, although the drift is not yet under the main ore-shoot.

Wallace, Oct. 19.

MICHIGAN.

KEWEENAW COUNTY.

Active exploratory work, consisting of diamond-drilling and trenching, is going on at the Seneca property. The drilling is being done to determine the line of strike and the dip of the lode in order to properly sink the shaft. A trench about 5 ft. deep some 600 ft. from the northeastern boundary of the property showed the outcrop of the lode. This has greatly diminished the amount of drilling that would have otherwise been necessary. It also shows that the Kearsarge lode extends into the Seneca property. The Kearsarge lode, which makes such a decided bend to the westward in the Gratiot property of the Calumet & Hecla Co., seems to again assume its former strike in the Seneca, and so this new shaft will probably line up with those of the Ojibway.—The bottom 50 ft. of the No. 1 shaft of the Medora mine belonging to the Keweenaw Copper Co. is in good ore.—The buildings on the No. 18 location on the Osceola amygdaloid are being erected rapidly. The ground is being broken for the No. 18 shaft, which is to be of three compartments. The ladder-way and pipe compartment will be placed in the centre. The heavy I-beam bearers are being put in place.—A new wooden shaft-house is being built at the No. 17 shaft of the Calumet & Hecla on the Osceola amygdaloid. This is similar in size and design to those at the No. 19, 20, and 21 shafts on the Kearsarge lode.—The overburden is being removed at the No. 1 shaft of the Ojibway. Concreting has begun at the No. 2 shaft, which is now about 100 ft. deep. At this shaft, which is being sunk in the foot-wall of the Kearsarge lode, the ore carries shot copper, and is of fair grade.

The shafts on the Montreal lode at Delaware have been shut down and all development work has been stopped. This was being done by the Calumet & Hecla. The unwatering of the old mine on the Allouez conglomerate at that point is still going on.—The Gratiot property, belonging to the Calumet & Hecla, north of Mohawk, is looking well. Driving is being done on the 200 and the 300-ft. levels. The Gratiot No. 1 shaft is now 475 ft. deep. Sinking is going on at No. 1 and No. 2 shafts.

NEVADA.

CHURCHILL COUNTY.

More ore has been shipped from Wonder this last week than in any previous week in its history. The Nevada Wonder shipped 16 tons; the Jack Pot, 23; the Vulture, 20 tons.—The ore from the Jack Pot comes mainly from the 200-ft. and 300-ft. levels.—At the Nevada Wonder the shaft is down 500 ft. and a level has been started at that depth.—The vein at the Ruby mine has been found again and a shipment of ore is expected to be made next week. The shaft was sunk on the vein, but at a depth of about 100 ft. the vein was cut off by a fault. A cross-cut was started and at a distance of 71 ft. cut the vein. Then the shaft was sunk farther and entered the vein at a farther depth of 54 feet.

ESMERALDA COUNTY.

Owing to fear of a run upon the local banks, Governor Sparks last week declared a legal holiday extending over a period of several days; this enabled the banks to have time to ship gold from the outside, so that there was no run upon them when they reopened. The Goldfield Stock Exchange was also closed the last of the week, but dealing in Nevada shares continued on the San Francisco Exchange. The local union has voted down the proposition to strike in sympathy with the Bishop, Cal., employees of the Nevada California Power Co.—The total output of the mines this week was 5,390 tons of an estimated value of \$508,920. The Mohawk Jumbo shipped 730 tons; Mohawk

Combination, 520; Mohawk, 2,375; Begole lease, 482; Combination Fraction, 62; Combination, 5; Hayes & Monnette dump, 53; Little Florence, 260; Florence L. & M. Co., 110; Florence Annex, 35; Rogers Goldfield Syndicate, 15; St. Ives mine, 26; Codd lease on St. Ives, 17; treated at Combination mill, 560; treated at Kinkead mill, 140 tons.—The Goldfield Consolidated is negotiating for a lease on the Best & Belcher mill at Virginia City, which has a capacity of 150 to 200 tons per day. The company is also negotiating for two other mills, and if these deals are consummated it will be in position to be independent of the smelters. The Kinkead and the Combination mills now treat about 800 tons per week.—The Mohawk Jumbo lease of the Jumbo Extension has been closed down since the 21st, owing to a dispute between the Jumbo Extension and the Mohawk companies over the boundary line between the two properties. A joint survey is being made to determine this.—Last week Thursday the Rogers syndicate found a good body of ore on the Red King claim of the Florence property. This ore was struck on the 409-ft. level at a point 175

developed. The orebodies have been exposed by a 150-ft. tunnel, and a 40-ft. incline shaft.—A good ledge of high-grade gold ore is being developed in the Le Maine-Phillips property.—The main shaft at the Golden Eva will be sunk to the 200-ft. point and levels opened at advantageous points. The main shaft is down 70 ft. with several small shafts and tunnels on the property. The ledge is four feet wide and assays from \$40 to \$60 per ton in gold. The mine was recently purchased from A. R. Harcomb by J. H. Dorst and C. H. Snow.—A small shoot of ore running 400 oz. silver per ton has been struck on the 230-ft. level in the Little Giant. The mine contains ore carrying lead, silver and gold and has been a producer for over 30 years.—Excellent ore is being developed in both shafts of the Black Jack. The mine is controlled by a syndicate of Salt Lake men.—Several important discoveries of lead, copper, gold and silver veins have been made during the present summer near Battle Mountain, and it is thought that section will in time rank among the important mining districts of Nevada. Salt Lake people have been particularly active in securing promising properties there.

Austin, Oct. 24.

LYON COUNTY.

The Nevada-Douglas company is working again with a full force of men. The winze from the north drift on the 550-ft. level of the Ludwig is still in high-grade copper ore. As yet the vein has not been reached in the cross-cut on the 650-ft. level, it being still in the limestone hanging wall. No stoping has been done in the orebody on the 550-ft. level. Water-pipe is being put in to bring water from the Nevada-Douglas tanks to the Ludwig shaft and an air-pipe is also being put in to run the hoist and air-drills at the Ludwig.—At the Mason Valley mine water has been met with in the winze from the upper adit at a depth of 50 ft.; the sinking has stopped until a pump can be installed. The lower adit has not cut the vein as yet.

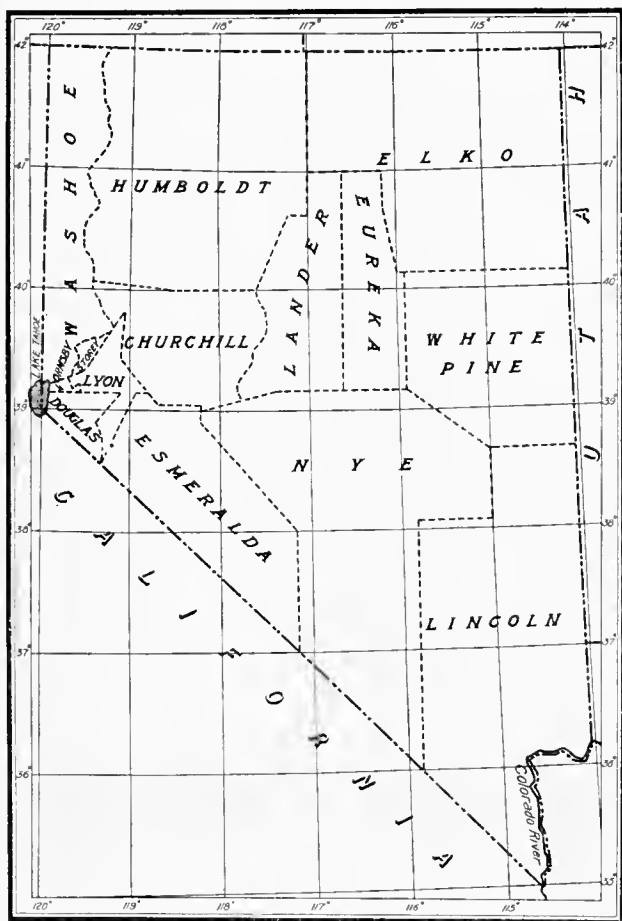

NYE COUNTY.

(Special Correspondence.)—Ground will be broken this week for the Homestake-King 20-stamp mill, in which amalgamation, concentration, and cyanidation will be used.—A trial run is being made this week at the Gold Bullfrog mill. This mill was completed some time ago but owing to an insufficiency of water, the commencement of operations has been deferred until the present. A well drilled on the property to a depth of 800 ft. has produced water enough to run the mill about half the time.—The Phillips & Moesser lease on the Gibraltar continues to sack several tons of ore daily which is said to average a little over \$200. The outcome of this lease will doubtlessly encourage others in this district to make ventures along this line.—Work on the 500-ft. level of the Mayflower has been suspended for the present until the pump can be installed, but the vein on that level had been cross-cut for a distance of 22 ft. with an average value of \$18 per ton.

Rhyolite, Oct. 23.

The ore shipments from Tonopah mines for the week ending Oct. 15 was 6,732 tons. The Tonopah Mining Co. shipped 4,466 tons; the Belmont Development Co., 1,676; West End, 45; John Gregovich, 21; Tonopah Extension, 263; Jim Butler, 100; Montana-Tonopah, 60 tons.—The mills at Miller's siding, which were shut-down several days last week, in order to relieve the fire-boxes and overhaul the boilers, are running again.—Development work continues at the Tonopah-California, but although some small bodies of ore have been found, no large orebodies have been as yet developed. In the future most of the work will be confined to the 600 and the 675-ft. levels.—The Supreme Court of the United States has decided in favor of the North Star company the case of Porter et al. v. Tonopah North Star T. & D. Co. The plaintiffs claimed the property on Mizpah hill under an alleged mining location known as the 'Dave Lewis Hope.'

At the Wolfstone the miners began stoping last week so as to have ore broken when the Lemmon mill starts.—The Manhattan Consolidated has 600 tons of ore sacked ready to send to the Manhattan Ore Reduction company's stamp-mill when it starts.

The Counties of Nevada.

ft. northwest of the shaft.—Rich ore has been struck at the Sandstorm mine in the Parkison & Erbel lease; it is supposed to be an extension of the orebody worked by Loftus & Davis in Block 5 three years ago. The lease has still almost a year to run, as work began on Oct. 15, the ore being struck almost immediately.

LANDER COUNTY.

(Special Correspondence).—The district surrounding Austin is attracting considerable attention from mining men, and several important deals have been consummated during the past few months. Many of the old mines are receiving renewed attention and several promising prospects have been bonded for development. It seems as if this famous old camp is destined to enjoy a measure of its old-time prosperity when it was one of the most active camps in the West.—The Copper Canyon mine, near Battle Mountain, is steadily shipping large quantities of high-grade copper ore. Much native copper has been extracted.—The Nevada Copper Butte M. Co. is developing five promising claims near Valmy.—The Pedro group has been bonded by a strong company and will be energetically de-

Camp Bird Annual Report.—Interesting Data.—Quarterly Report.—Oroville Dredging. — Somera. — Mexico Mines. — Esperanza Profits.—Results at the Dolores.—Gloomy Mining Market.

A complete presentment of the position and prospects of the Camp Bird Co. is to be found in the annual report supplemented by the Chairman's address at the recent stockholders' meeting. The more than usually intelligent questions put by some of the stockholders present at the meeting elicited particulars of interest not included in the annual reports. The Chairman made a good point of the fact that in spite of the large sums required for the reconstruction of the mill the total expenditure on the properties and their equipment still corresponded very nearly to the issued share capital of the Company (£820,000). The value of the ore treated was much higher than the average of the mine in the past, namely £7 4s. 2d. against £5 17s. 4d. the previous year. This was owing to the policy of catching up the financial position during the second half of the year which had fallen back during the first half, or reconstruction period, when the work in the mine was suspended. For the same reason the standing and other charges per ton were higher, but less money had naturally been spent in blocking out ore, with the result that the cost per ton worked out at 17s. 9d. against 20s. 6d. for the previous year. The Company's earnings from 38,295 tons dry ore crushed amounted to £179,681. After deducting the payment to Mr. Walsh of £38,591, cost of shares in Imogene Basin Gold Mines Co. £29,310 (out of a total of £30,310), and London Office expenses, and providing for depreciations and income tax, there was a net balance for the year of £98,116. Dividends aggregating 2s. 6d. per share (12½%) absorbed this amount together with £4,384 from the previous year's profits, and the credit balance carried forward as on May 1, 1907, was £111,237. Mr. Walsh had received in all, as his 25% of net proceeds, £170,000, leaving a further amount of £230,000 receivable out of future profits to complete the contract with him. The Company owns 571,230 shares of \$1 each in the Imogene Basin Gold Mines Co. out of a total capital of \$3,000,000. No further work was done on this property owing to lack of labor. The new Camp Bird mill of 60 stamps was designed with special reference in the main to the practice of the old mill, but with an increase in the weight of the stamps from 850 to 1,050 lb. The ore reserves were drawn upon during the year to the extent of the net earnings with the exception of £15,000, which amount resulted from the year's development, so that the value in sight declined from £881,000 to £717,000. The exploratory work, which aggregated 2,997 ft., is described in the Consulting Engineer's report as having shown "fairly satisfactory" results. This is scarcely borne out by the particulars in the General Manager's report, most of the points referred to being either in low-grade or unprofitable ore. At the same time much contemplated and important work remained in abeyance owing to shortage of workmen after the six months stoppage and the General Manager mentions additional developments which should be carried out in "promising territory." The Chairman endeavored to raise the stockholders' hopes by reminding them that they had three years' ore in reserve and a very large working capital with which to prosecute development work. Mr. A. C. Beatty reported that the development work in depth had only shown small irregular bodies of

ore, but that it has not advanced sufficiently to allow him to express an opinion as regards the ultimate outcome of the work in depth. Mr. Beatty was confident that large ore reserves would be opened up in the western part of the mine, and he seemed to have no doubt that the result of development work in that direction would give satisfactory results.

Since the annual meeting, the Camp Bird quarterly report to July 31 has been issued, showing increased activity in all departments. The net earnings at the mine amounted to £373,714. The developments totaled 1,459 ft. with improvements in value and appearance of the vein at several points. Dividend No. 22 of 1s. per share (£41,000) was paid in August. A melancholy interest attaches to this report. It is the last that will be issued over the signature of C. R. O'Flaherty, the late Secretary, that courteous and capable official having passed away after a short illness.

Oroville Dredging paid its eighth quarterly dividend of 12½ cents per \$5 share (700,000 shares) on September 30. During that month the weekly returns fell off, owing to interruption of the power supply by a severe storm. The total gold yielded from August 1, 1905, to September 9, 1907 is given as \$1,682,580.

The report of the Somera Gold Mining Co. (Mexico) for the period from the incorporation of the company (December 14, 1905) to June 30, 1907, states that of the authorized capital of £500,000, 234,000 shares of £1 each, fully paid up, have been allotted to the El Oro Mining & Railway Co., in payment for the property, and 216,000 working capital shares have been subscribed for and allotted, upon which the sum of 5s. per share has been called up.

The directors propose to make a further call of 5s. per share before the end of the year. During the period under review a sum of £30,951 has been expended on the installation of surface equipment and machinery and upon development work underground. Mr. R. M. Raymond reports that the drift northward upon the Victoria vein has now advanced for a length of 80 ft. into the orebody and for that distance it shows a width of 2 ft. 4 in. and an average value of \$59.34 gold and 20.9 oz. silver per ton.

The profit and loss account of Mexico Mines of El Oro for the year ended June 30 shows that, after providing for all general expenditure in Mexico and London and a small sum for depreciation, a net realized profit of £41,107 has been earned. The new mill was not in operation during the period under review, and this profit arose from the sale of 2,739 tons of high-grade ore, which realized £61,453. The sale of ore has enabled the directors to provide the funds necessary for the erection of the new mill and for the development of the mine and to meet all general expenditure. Mr. Raymond estimates the amount of ore at present available for extraction at 178,000 tons, and places its average value at \$11.53 gold and 6.9 oz. silver per ton, but does not include in this estimate the high-grade shipping ore exposed in the stopes above the No. 3 and No. 4 levels. At the annual meeting held this week the chairman, Mr. R. T. Bayliss, pointed out with satisfaction that the sales of high-grade ore had provided all the money required for the erection of the new mill and for surface equipment and for the development of the mine and all general expenditure. He regretted that it has taken longer to construct the new reduction works than was at first anticipated, partly, but not entirely due to the fact that, owing to the congestion of traffic on the railways of the United States, great delay occurred in delivery of machinery. The mill as now completed is highly efficient and it is expected to treat 200 tons per day when in full working order with 90% extraction. The estimated profit is \$7 per ton on

ore of a gross value of \$15, which will yield an income of close on £100,000 per annum. The chairman described the results of the developments at many of the points in the mine and said that in view of the lengths already opened on the two orebodies on the No. 3 and No. 4 levels, he felt very hopeful that there would be a considerable income from high-grade ore, and without in any way desiring to suggest that they had another Esperanza West vein there as yet, he thought that from time to time and from different portions of the mine, they would pick up a considerable amount of similar sort of stuff.

The profits of Esperanza (Mexico) for May, June, July, and August, make up a total in America of \$670,000 in round figures. The last quarterly dividends declared of 5s. 6d. per share (£125,125) is payable on October 19. Another Mexican mine, the Dolores, is doing well, as will be seen from the following particulars:

	Net tons ore treated.			Average value.	Monthly profit.
	From mine.	From dump.	Pan tallying.		
July.....	986½	95¼	\$89.14 19.12	\$46,000
August.....	1,146½	267½	39.84 81.87 44.71	\$38,000

During July there were break-downs in the mill, and in August the returns suffered from lack of fuel and labor. In these respects the outlook for September is said to have improved. The mine continues to open up well in the deepest workings. The San Francisco cross-cut has encountered a heavy flow of water, which would seem to presage proximity to the vein.

The promise of improvement in the mining markets, noted at the beginning of September, has not materialized. Mines have suffered in sympathy with investment stocks from the unsettled state of the great international markets, coupled with the slumps in copper and tin.

Mexico City.

Effects of Low Metal Prices.—Several Mines and Smelters Shut Down.—The Belt Railroad at Guanajuato.—Prospecting the Veta Madre.

As was to be expected, and as has been rather anticipated in a former letter to the PRESS, the present low price of all the metals has been felt and is having its effect throughout the Republic of Mexico. From the daily press it is perhaps generally known that there has been a material curtailment of the production of copper in Cananea and throughout the State of Sonora. And even before this action by the large producers at Cananea, the small properties in almost every district where copper is the principal product had closed, only such larger properties continuing in operation as wished to maintain their organizations or by reason of a high-grade ore or other (as gold and silver) contents could afford to continue production. And many that were simply in a stage of development have also closed. Among the more important properties in the central part of the Republic that have ceased production are those of the Coahuila Mining & Smelting Co., near Viesca, State of Coahuila; the mines of the Aguascalientes Metal Co., in Tepezala, Aguascalientes, controlled by the Doerr Bros., one of whom is manager of the Aguascalientes smelter, and which mines were shipping some 100 tons daily of ore running about 3 to 4% copper and 6 oz. silver per ton; but the Guggenheim properties at Tepe-

zala are still working in order to supply as much ore as possible for the A. S. & R. Co.'s smelter at Aguascalientes. At Jimenez, however, the Jibosa mine of the American Smelters Security Co. has closed down, as have those of the same company at Velardeña, State of Durango. These Velardeña properties are of two classes, copper and lead, but in both groups the ore, though in large bodies, is low-grade; and it is said that neither could be made to pay at the present prices of those metals. Whether this will lead to the closing down of the A. S. & R. Co.'s new plant at Velardeña cannot be learned, though considerable custom ore is still being received there as usual. But it is not alone the copper properties that have been forced to curtail, for the continued fall in the prices of silver, lead, and zinc has necessitated the closing down of some of the producers of these metals also, or the cutting off of the low-grade ores and limiting the production to the high-grade material. What effect the financial difficulties, that have shown up in New York this week, may have on the mining industry in Mexico cannot as yet be surmised. Certain it is that it will cut off the promotion of any new large enterprises. It is pleasing to note, though, that as yet it has not seemed to affect the much-needed belt railroad for Guanajuato, as a contract has been given to E. J. White for the

Mexico.

first section, which will take in the San Prospero, the Bustos mill of the Guanajuato Reduction & Mines Co., the Sirena of the Guanajuato Consolidated, and the Aparecida, in short, Guanajuato proper, and as several hundred men are at work it is expected that this section may be completed by April. The estimated cost for the entire line is \$35,000 per km., or \$2,000,000 for the 60 km. The three kilometres between the Pinguico mine and mill is already completed and in operation with mule-power pending the arrival of the Shay engines to be used on the belt line. It is also gratifying to be able to state that the grading of the Mexican Central branch from Marfil into Guanajuato has been completed, the rails are being laid and there are hopes that trains may be running into Guanajuato before the end of the year. It is to be hoped also that an end has been put to the robberies in this district, which, among other things, resulted in the murder of George W. Rose of the Nayal company and carrying off of \$15,000 worth of bullion from the Guanajuato Consolidated (since recovered, however, and it is believed that the leaders of the gang are in custody). While speaking of Guanajuato, I should mention something of the plans of the Mineral Development Co. It is the intention of this company to sink a shaft to a depth of 2,500 ft. and then cross-cut to and prospect the Mother Lode at that depth. The shaft has

already attained a depth of 850 ft., and to encourage the project the Mexican Government has granted a concession of P100 for each foot driven below the 1,500-ft. mark. This is valuable evidence of federal support and is said to be due to the diplomacy of Theodore Dwight, who succeeded in demonstrating to President Diaz that this scheme to explore the Veta Madre was of first-rate importance.

In regard to the Guerra at Tirano mill, in Chihuahua, recently mentioned in these pages, it may be added that the original mill was ordered at San Francisco in December, 1905. Owing to the congested condition of the trails and the scarcity of mules, hardly any of the machinery reached the mine until October, 1906, and the last of it not until February, 1907. The machinery consisted of three 50-hp. boilers, 75-hp. twin engines, 2 crushers, 3 sets of rolls, 2 elevators, and 3 trommel screens, redwood leaching vats, piping, roofing iron, etc. On account of the delay the plans of the mill were changed from a stereotyped flat-site mill to one more adapted to the locality, that is, a gravity mill throughout, with shaking screens, ample elevation being allowed between the last rolls and the leaching vats, to permit of considerable additional re-grinding machinery and other improvements for successful operation, such as sizing cones, spitzkasten, slime-agitator, filter-press, etc. The lumber for this modified mill was cut at a considerable distance from the millsite and with the greatest difficulty was dragged over tortuous steep mountain trails. The building was completed simultaneously with the arrival of the last of the machinery, nearly sixteen months from the start. O. B. Finn resigned at the end of February, 1907, and his successor (Frank Holmes) arrived in March. The first ore put through the mill demonstrated that additional disintegrators would have to be added at once. The new manager decided on stamps and immediately ordered 10; these were placed in the building awaiting them. This of itself, for that country, was a good job. The ore is a silver sulphide with a little gold. The mine was developed to the 500-ft. level and a rich core in the midst of the main orebody has proved continuous to that depth. It was estimated that there was enough of this high-grade in sight to offset the cost of the mill, but it is not at all likely that it has been mined and realized upon by this time.

Butte, Montana.

The Barnes-King Fiasco.—Butte Coalition.—West Colusa Fire Underground.—Curtailment of Output.—Raven Mines.—Snowstorm Passes Dividend.—Smelters Close Down.

Another interesting development in the Barnes-King fiasco is the denial of Walter Harvey Weed that he had anything to do with the reports made on the property for the promoters. Mr. Weed says he never had any connection with the Barnes-King Co.; he explains that once he made an examination of the Barnes-King mine in behalf of a client who was considering the purchase of the property, but who concluded not to go any further in the matter. This examination, says Mr. Weed, was geological, and he says he neither measured the ore reserves nor made any valuation. The fact remains that the promoters of the Barnes-King deal used a report purporting to have been made by Mr. Weed, although only portions of such report were quoted in the advance papers, and a part of the alleged report was made up of assays of ore alleged to have been taken from the mines. No one knowing Mr. Weed will doubt his denial, but the question arises: Where did the promoters get the report and assays purporting to carry Mr. Weed's endorsement, and alleged to

be his own work? Was it an absolute fabrication, or were portions of the report he made to other clients used by the promoters of the Barnes-King? The new board of directors of the Barnes-King Co. has not yet been able to get together the papers and books of the company, and little progress has been made toward preparing a statement for the stockholders to show what became of the \$2,000,000 subscribed by them for the purchase of the \$50,000 property. Two experts have been at work on the mine for a week. Some of the deluded subscribers have served formal legal notice on the directors to bring action against the promoters and former directors for an accounting and to recover the money alleged to have been obtained by fraud.

The Butte Coalition Co., since the curtailment of copper production, has confined its operations to the Rarus mine, from which it is shipping an average of 500 tons of ore per day. The ore is of good grade, equal to the average from the mine of the North Butte Co. The Coalition has stopped all construction work, including the extensive operations on the surface of the Tramway, where a big hoist is being built jointly by that company and the Butte & Boston. The only work now going on there

Montana.

is the erection of the big steel head-frame, which is being done under contract. All the other work has so far advanced that it can be resumed at any time and finished before it is needed. At the Minnie Healey mine nothing is being done by the Coalition, but the Boston & Montana is opening the Minnie Healey shaft and putting it in condition for use as a vent for the smoke from the West Colusa mine. The Minnie Healey is entirely free from gas and smoke, and it has been demonstrated that there has been no fire in the workings of that property, and that the fire is in the West Colusa, an adjoining and connecting property owned by the Boston & Montana. The fire has not abated in the slightest, but it will be but a question of time when it will be thoroughly confined and controlled, as the Boston & Montana is sinking and opening four shafts to the fire zone, including a new shaft on the Leonard (being sunk right over the fire), two old shafts on the Gambetta, and the Minnie Healey shaft. The company will also sink the shaft of the Alex. Scott mine, owned by the Butte-Montana Co., 500 ft. deeper, having secured permission to use it as an air and working shaft until the fire is under control. The Butte-Montana Co. will derive great benefit through the arrangement, as it will save the cost of sinking the shaft, which it would have been under the necessity of doing itself.

There is rumor of a possibility that the Butte Coalition Co. will pass its next quarterly dividend. There are

also persistent rumors that the company may suspend operations entirely until the metal market improves. It cost the Coalition an excess of 10c. per pound to produce its copper last year, and at present prices, even if its product could be sold, there would be scarcely any profit. A. C. Carson, the manager, is now at New York in consultation with the Eastern officials.—It is not yet certain that there will not be a further curtailment on the part of the other companies, but the Butte officials of the Amalgamated and North Butte companies hope there will be no necessity for such a step. The North Butte probably reduced its working force more than any of the other companies. The North Butte is mining some very rich ore again, however. The ore that comes from the 1,800-ft. level of the Edith May averages about 11% copper. Very little dead work is being done by the company at present.—The Anaconda, Boston & Montana, Butte & Boston, Parrot, and Washoe companies continue at about the same rate of production as they did in the early part of October, about 26% of the normal.

E. C. Frisbie of Hartford, Conn., president of the Raven Mining Co., and W. Spencer Hutchinson, the company's consulting engineer, were here during the past week to inspect the work being done. Mr. Frisbie says the property has never been in better physical condition than it is now, and that the future is promising. The incline shaft on the Raven claim is now down 947 ft. and is timbered nearly to the bottom. The station at the 900 has been completed and sinking has been resumed. The shaft will be taken to the 1,100-ft. level, from which point a cross-cut will be driven to the vein and driving done to determine the extent of the orebodies. The stringency at the money centres and the demoralized state of the copper market have had no effect on the operations of the Raven Co., the work of development having progressed steadily since the reorganization.

The Snowstorm Mining Co., which passed its October dividend, will also pass the November dividend. The company has been distributing \$45,000 monthly since the first of the year, but accumulated no surplus, the earnings having been expended in improvements and dividends as fast as accumulated. The company had been treating 150 tons of low-grade ore at its leaching plant near the mine and shipped 300 tons daily of first-class to the smelters. Last week an accident to the mill necessitated a closing of the plant, and about the same time the smelters notified the company that only a limited amount of ore could be received because of the unsettled condition of the metal market. Shipments were therefore cut about in half. The manager says a resumption of work at the mill will depend on the price of copper, as at present prices the mill cannot be operated at a profit, it having been treating ore that averaged 2½% copper. The working force at the mine has also been reduced. T. L. Greenough, the president, says there is enough ore blocked out in the mine to last for three years, and that the ore will average 5%. Some time ago Snowstorm stock was selling above \$4 per share. It is now selling around 90c. Mining men who have examined the property have been enthusiastic in their reports about the ore reserves, but the ore is of a peculiar character that is purchased by the smelters only in limited quantities.

The East Helena smelter, a branch of the American Smelting & Refining Co., which has been taking a lot of ore from small operators in Butte and elsewhere throughout the Northwest, has given notice that for some time no more ore will be accepted, except from mines having contracts with the smelter. Similar notices have also been given by the Utah smelters and the Clark Reduction works in Butte, because of the condition of the metal market.

Denver, Colorado.

Treatment Charges on Cripple Creek Ore.—The Golden Cycle Mill.—Another Mill at Colorado City.

The animated discussion that has gone on for a long time regarding treatment charges on Cripple Creek ore has been given a new impetus by the developments of the past week. To go back to the beginning, the lessee has in the past had the choice of either sending his ore to the Pueblo smelters or to the chlorination-cyanide mills of the United States Reduction & Refining Co. at Colorado City and Florence. The treatment charges of the smelters have been high, but they are justified by the smelters on the ground that the ores are not easy to flux and are generally too fine to be smelted directly. When the modified Huntington-Heberlein process was introduced into the Pueblo plants it was found that the fine ore from Cripple Creek was admirable as the stiffener in the pot charges, and can be used in place of lime. This did away with one difficulty, but the smelters did not reduce their charges until obliged to do so by a cut in rates levied by the mills.

The 'mill trust,' as the U. S. R. & R. Co. is generally known, maintained a sliding scale of charges based upon the gold content of the ores, varying from \$6.25 per ton for ore under \$10 in value up to \$14 for those over \$150 per ton, which it claimed to be only a reasonable amount in excess of the cost of treatment. To this the miner made the same reply as the Missourian, and, believing himself caught between the devil and the deep sea, loudly deplored his fate. Then the Golden Cycle Mining & Milling Co., itself operating mines and leases, came forth like a noble St. George to slay the dragon. The site and plant of the old Telluride company, now defunct, were bought and Philip Argall was engaged to design a plant to operate along the lines laid down by Skewes and Marriner in Western Australia, and a \$750,000 plant was constructed. Early in the spring of 1907 this began operations with a scale of treatment charges so far below those then in force that almost immediately the larger part of the custom ore was diverted to its 750-ton per day plant. Most of these producers entered into a contract, which at that time appeared a wise movement, though subsequent developments proved otherwise. The smelters reduced their charges on such ores as are desirable for them, underbidding the Golden Cycle enough to get all they wanted. The U. S. R. & R. Co. simply closed down its Florence plant, reduced the tonnage at its Colorado City plant, and sullenly announced that it was prepared to wait until the Golden Cycle got tired of its rates. What the success of the Golden Cycle was is a little difficult to learn, as its period of activity was so brief. Many conflicting statements are made, but the general truth seems to be that the mill was well designed, except as to its amalgamated plates and the use of mercury, both of which had speedily to be abandoned. The old Holthoff-Wethey furnaces retained from the Telluride plant were also entirely unsatisfactory, improper draft conditions made it impossible to heat the furnaces hot enough for satisfactory roasting, and finally led to the explosion of unburned gases that caused the fire which resulted in the destruction of the roasting, crushing, and sampling departments.

In its management the plant was even more unfortunate. It was the worst of judgment to dispense with Mr. Argall's services before the plant was finished; it was equally so to attempt to start up a large plant in which there are so many new features with only the assistance of men whose experience in even small plants of simple type was painfully limited. Such difficulties as were encountered are most largely to be attributed to the lat-

ter, although attempts were made to magnify the former. Archangels may be able to design plants so that nothing in them need to be changed; it is folly to expect a human being to do it.

Within an extremely brief period after the start, the Golden Cycle mill was destroyed by fire, only the transformer house and cyanide plant remaining intact. Since that time it has been treating the tailing dump of the Telluride plant. Although announcements are made that it will immediately be rebuilt, the rate at which the work of rebuilding scarcely justifies any very high hopes on the part of those who were bound by contract. Within the week the U. S. R. & R. Co. has published a new scale of treatment charges, about 15 to 20% lower than those formerly in force. The reduction is not in the nature of a 'bargain sale' but simply a recognition that the charges have been too high. This now makes it the more doubtful that the Golden Cycle plant will resume operations.

Within the week it has also been announced that James Burns is to build a 750-ton per day mill at Colorado City. It is also said, with a knowing look, that F. A. Heinze is back of Mr. Burns in the movement. But, judging from his operations in Wall Street, Mr. Heinze is so far behind as to be indistinguishable in the rear, while if Mr. Burns is no more successful in milling than he is in lawsuits, he is also not likely to become a serious factor in this question. What Colorado City needs is not more mills, but better mills. Indeed, it begins to seem as though the proper place for a mill is in the mining district and not at a distance.

Salt Lake, Utah.

Important Suit.—Shipments From Tintic.—Effects of Low Copper.—Mining News From Stockton.—Annual Meetings.—Diminished Silver Receipts.—The Honerine Company

The ore and bullion settlements reported at the close of business hours last week amounted to \$743,000.

An important mining suit is to be filed in a few days; it will involve the ownership to a large block of stock in the Colorado mine, one of the principal producers and dividend-payers of Tintic. The plaintiff is Joseph L. Wilson, an old prospector, who was one of the original incorporators of the Colorado company. Wilson returned to the State a few weeks ago after an absence of more than five years and he is now seeking to recover property of which, he claims, he has been unjustly deprived and which is valued at more than \$315,000. Wilson formerly owned a third of the capital stock of the Colorado company, but through sickness and poverty he was driven to part with all but 30,000 shares. During his absence, so Wilson alleges, the company was re-organized; the capital was increased from 250,000 shares of the par value of \$1 each to 1,000,000 shares of the par value of \$1. Wilson claims that he was never consulted about this change in the company's capitalization, although he was a director of the old corporation, and also claims that not all of the stock to which he was entitled had been issued to him for the reason that the shares were pooled for a stipulated length of time. It was this pooling arrangement, he declares, which caused him to feel that his interests were safe during his absence. When Wilson went away, however, the Colorado was nothing more than a prospect; but now it is regarded as being one of the leading mines of the State.

Ore shipments from Tintic last week amounted to 148 carloads, the contributing mines and amounts being: Ajax, 2; Beck Tunnel, 5; Bullion Beck, 3; Carisa, 2; Colorado, 11; Centennial Eureka, 51; Eagle & Blue Bell, 8; Eureka Hill, 6; Grand Central, 7; Gemini, 5; Lower Mammoth, 7; May Day, 9; Mammoth, 3; Scranton, 7; Tintic Iron,

12; Uncle Sam Con., 6; Victor Con., 1; Yankee Con., 4 carloads.—The new equipment for the May Day mill has been installed and the capacity of the plant has been considerably increased.—Tracklaying is progressing satisfactorily on the Eureka Hill railroad, which is to connect the principal mines of the Tintic district with the new smelter being erected by the Tintic Smelting Co. The road will be 10 miles long when completed. The building of the smelter is going ahead steadily and will be completed about the first of January.

It is claimed that fully 2,000 less men are working in the mines of Bingham than was the case 60 days ago, and there is every reason to believe that this statement is correct. With the exception of the Utah Consolidated, Utah Copper, and one or two others, all of the mines of the camp have either curtailed their operations or have shut-down entirely. The Ohio Copper Co., while it is

Utah.

pushing work on its 2,000-ton concentrating mill with all the vigor possible, has ceased doing any development work in the mine. The latter, however, is in condition to supply the mill with ore for a long time to come. In all probability the plant will be started on ore delivered over the tracks of the Rio Grande Western. The completion of the Mascott tunnel is not absolutely essential to the starting of the new mill; yet the expense will be somewhat greater—probably 10 cents per ton.—The United States Supreme Court has rendered a decision in the case of Leonidas M. Lawson v. United States Mining Co., which gives the defendant title to ores contained in the Ashton and Kempton lodes in Bingham, valued at about \$3,000,000. Col. E. A. Wall, of Salt Lake, is the heaviest loser by reason of the verdict. The case has been in litigation for six or seven years and both sides have been to great expense in fighting it.

The annual meeting of the Honerine Mining Co., with properties in the Stockton mining district, resulted in the re-election of the retiring board of directors and the election of G. A. Baird of Chicago as president and Charles Dupont of Salt Lake, secretary. An assessment of 45 cents per share has been levied to pay off the existing indebtedness of the corporation, which amounts to over \$200,000. There is a plan on foot to bring about a merger with adjoining properties, which can be operated through

the Honerine adit. It is expected that the new equipment installed in the mill of the New Stockton Mining Co. will be in commission by November 1. The enlarged plant will treat 150 tons of ore per day.

The annual meeting of shareholders of the Ajax Mining Co., held during the week, resulted in the election of Thomas Weir, president; H. G. McMillen, vice-president, and J. M. Burt, secretary. During the fiscal year ending October 1, about 1,000 ft. of development work was performed and 8,091 tons of ore marketed. The year began with an indebtedness of about \$40,000 and closed with a surplus of \$20,000. The properties of the company are in the Tintic district.—The board of directors of the Little Chief Mining Co., operating at Tintic, has ordered development work suspended. The company has an indebtedness of over \$14,000 and no means of raising funds except by assessments, which are limited by law to \$2,000 monthly. The Little Chief mine is developed to a little over 1,000 ft., but as yet no persistent orebodies have been encountered.—The South Columbus Mining Co. has four faces moving toward ore and in two of them it has been encountered within the past week, demonstrating that the deposits found in the upper tunnel persist in depth. This mine was splendidly equipped during the past year and has one of the best plants in the camp of Alta.

The smelting companies operating in Utah have all called upon producers to curtail their output and, in the main, the request has been complied with. Smelter managers complain of a congested state of affairs at their plants, and that more ore has been received than they can conveniently take care of. Besides, the difficulty experienced in realizing promptly from the sale of their product has called for the adoption of protective measures.

Toronto, Canada.

Illegal Operations.—A New Smelter.—Ore Shipments From Cobalt.—News From the Mines.—Rich Strikes.

When the case against Law & Co., mining brokers, of Toronto, charged with selling mining stock in the Highland Mary Mining Co., of Larder Lake, without furnishing the information regarding the company and its property required by law, came up in the Police Court yesterday, the defendants did not appear. It was stated by J. W. I. Corley, Crown prosecutor, that efforts to serve Law personally with a summons had been unavailing, as he was said to be at Larder Lake. He is believed to be keeping out of the way to avoid service. The case was accordingly enlarged until October 30.

Thomas W. Gibson, Deputy Minister of Mines, and Willet G. Miller, Provincial Geologist, have returned from an inspection of the Deloro smelter, near Marmora, Ontario, which is being refitted for the purpose of handling Cobalt ore. It is expected to be ready for operation in about a month and will treat from 15 to 20 tons of ore per day. Speaking of the smelters and concentrating plants now either finished or in course of completion, Mr. Miller says: "When these various plants are in operation the Cobalt camp will be in a much better position than it has hitherto been, as its weak point has been in connection with the refining of its ores. When the mines were discovered no suitable plant for handling these complex ores existed in North America."

Shipments from Cobalt for the week ending October 19 were 369 tons from the following mines: Drummond, 32 tons; Kerr Lake (Jacobs), 30; La Rose, 140; McKinley-Darragh, 133; and O'Brien, 34. Of this three carloads from the McKinley-Darragh and two from the La Rose were shipped to the Denver smelters. The total shipments from January 1 of the present year to October 19

were 10,043 tons.—George F. Morton, of Morton & Co., who returned this week from Cobalt, states that the Nipissing was making preparations to carry on underground work during the winter months. Surface work will be discontinued and all work will be done in drifts and cross-cuts. The Kendall vein is showing well at a depth of 90 ft. The big silver vein on the Hudson Bay property has been traced on the north lot of the Nipissing and the large cobalt vein uncovered on the Hudson Bay some weeks ago trends in the same direction.—The Foster company has signed a contract with the Cobalt Concentrators Ltd. for the erection of a concentrator on their property.—The report of the Tretheway directors,

Map Showing Position of Cobalt and New Districts in Ontario.

covering the period from June 13, 1906 to August 31, 1907, shows total revenue \$249,262; operating and other expenses, \$124,739, leaving a surplus of \$124,522, out of which \$75,636 has been paid in dividends.—On October 19, in the course of sinking on the big vein on the Temiskaming & Hudson Bay, discovered last March, a strike was made at 100 ft., at which depth the silver-bearing portion of the vein shows a width of 10 in. and is of great richness.—A rich strike has been made on the Sargesson property in the Portage Bay district, where a vein several feet wide has been found on the surface and traced a considerable distance, some assays showing 2,000 oz. silver per ton.—Another strike at the McKinley-Darragh is reported, the vein being 18 in. wide of cobalt-silver with an average yield of 4,000 oz. silver per ton. Another 20-stamp unit is being installed, making 40 stamps in all.—At the Cobalt Lake mine a depth of 26 ft. has been reached in the north shaft.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Capitalization of Rand Mines.

The Editor:

Sir—In the editorial columns of your issue of the 12th inst. I was much surprised to find an attack upon the integrity of the mining engineers of the Witwatersrand. As you are aware, practically 99% of the properties in that field are controlled by half a dozen financial houses, who employ a corresponding number of consulting engineers, consequently your charges are made against a very few men.

I think you must know of the custom prevailing in all English enterprises of keeping each man confined to his own special sphere of work. This is especially true on the Rand, and I speak from experience when I say that the engineers there were not consulted as to the amount of capitalization to be placed upon a property, the reason being that the financiers considered this was a matter belonging peculiarly to themselves. By far the greater portion of the deep-level ground of the Rand was purchased by the several controlling firms without asking for an opinion from the engineer; much of it was done, in fact, before his advent, and the latter was simply requested to lay out the ground and develop it after the company had been formed.

Your statement that many of the mining engineers "lured by opportunity of participating in big promotions, others carried away by an honest enthusiasm, did, indeed, give their authority to the over-capitalization, and, indirectly, to the wild dealing in shares," etc., is, in my opinion, most unjust and unfair. I do not know of a single engineer who has done this, nor do I agree with your statement as to the over-capitalization. The Rand Mines have an issued capital of £450,000, and paid 180% interest, in the shape of dividends, in 1906, equal to 9% on twenty times that valuation. The Witwatersrand Deep has an issued capital of £500,000 and is paying 40% upon that amount, and accumulating a surplus as well. To instance a later flotation—one that has occurred since the war—the Robinson Central Deep has an issued capital of £440,000 and is paying regularly 75% on that capital. I could cite dozens of other similar producing mines, if necessary, but it hardly seems worth while to take up your space. They certainly are not over-capitalized.

I am informed that the development in some of the deep-level mines is disappointing, causing some of them to now appear over-capitalized, but at the time the companies were formed the majority of them were not so, and the fact that the financial houses underwrote the working capital of many of these mines at 35 to 50 shillings per share to the extent of hundreds of thousands of pounds (which liability can never be avoided, although the shares may be bought in the open market for one-third or one-fourth of this amount), shows the honesty of their intentions at the time of making the flotation, and their belief in the value of the property. Such mines certainly do not deserve to be put on a par with the wild-cat flotations that one sees so much of nowadays in new mining camps, companies as devoid of working capital as they are of the means of raising it.

The value of the Rand was at first underestimated, as is the case in all new mining districts of lasting merit, and it was inevitable that speculation should follow upon the realization of the amount of gold to be won there,

but to say that the engineers lent, even indirectly, their authority to "wild dealing in shares" is not, in my opinion, called for or merited.

THOS. H. LEGGETT.

San Francisco, October 19.

Professional Customs.

[The questions to which reference is made in these letters will be found in our issues of October 5 and 12.—Editor.]

The Editor:

Sir—In answering the "searching" questions of T. S., it seems to me that these inquiries show a commercial rather than a professional spirit from one who, as he says, is at the beginning of his career. To make money rather than to strive for professional reputation seems to be the desire of most modern young men who are entering the profession of mining engineering. It strikes me that the first thing of importance is the building up of character and reputation, and that success in a money way will come as a result of this later on.

I shall attempt to answer the questions briefly and *seriatim*:

1. The fee should include all traveling and other expenses of the trip. Engineers of experience know well the cost of trips of this nature, and business men prefer to know the exact amount which the report is to cost them. Putting it in another way, I should charge a lump sum for doing the work, including traveling and other expenses.

2. An exchange of letters is generally sufficient to bind a bargain of this kind.

3. As to payment of fee, it is usual for an engineer to receive a retainer on account of his fee before leaving for the mine. This retainer can be anywhere from 10 to 50% of his fee, according to circumstances. Usually clients are willing to pay one-half of the amount of the fee as a retainer, and the balance upon the completion of the work.

4. No, an engineer in good standing is expected to furnish his own outfit, which should include such surveying instruments as he might need, drawing utensils, et cetera.

5. It is to avoid just such difficulties as are mentioned in this question that engineers should make a flat charge to include all of these contingencies.

6. It is better before starting on a trip to have an understanding with your client that no information is to be expected, unless otherwise provided for, until the completion of the report in writing. One of the most trying things to an engineer examining a property is to be required to give his opinion before he has had opportunity of going carefully over his report and checking his data, having his assays made, et cetera.

7. An engineer should not buy shares on information gained at the expense of his clients unless he first communicates with them. As to buying shares after his report is in, this is a question of conscience. It might be that his buying or selling of shares would work a distinct injury to his clients, as he may not be informed as to the object of his employment. It is better on the whole to leave the stock market entirely alone when engaged in confidential work of this nature.

8. I should consider that it was not legitimate to take advantage of your presence in a district to examine and report upon other properties for a fee unless with the permission of your employers.

9. There should be no objection to publishing in technical periodicals a description of the district visited, provided you obtain the permission of your clients to do

so. It is well to remember in this regard that all of the information which you obtain from a mining district while on a trip for which you are paid, belongs to the clients or client employing you. You have made a bargain to sell this information, and you should adhere strictly to your share of it.

10. It is not always expected that an engineer will say 'Yes' or 'No' as to a property, but it is better to give a definite and decided opinion in each case, if it is possible to do so. It must be remembered that a business man is acting upon your advice, and he must have a definite and decided opinion in each case. With regard to doing work upon the ground, the engineer is justified only in clearing out old drifts or putting his client to this expense after he has communicated with him.

BENJ. B. LAWRENCE.

New York, October 14.

The Editor:

Sir—Referring to the subject of professional ethics covered by the letter entitled 'Searching Questions' in your issue of October 5, I shall express my views *seriatim* in answer to them. But it must always be remembered that great latitude should be allowed in these matters, since the personal equation is a most important factor.

1. Upon jobs of short duration, it is better to take a fee rather than a salary. With responsible people I usually ask for one-half in advance, and the balance, with expense account, upon rendering the final report. Engagements lasting over a month had better be on a salary basis.

2. The contract should be clear, and in writing. It usually matters not whether it be made by formal document or in a letter. Telegrams are apt to be vague, and sometimes open to a variety of interpretation.

3. Certainly, and it is always the safest plan.

4. Yes.

5. (a) Yes.

(b) Yes.

(c) This question is open to the objection that if the engineer travels second class and charges the company for first, the company is not getting that for which it paid, since the moment the engineer accepts an engagement he is a representative of the company. Furthermore, it is always desirable for an engineer to travel as a gentleman, and not to appear cheap in any way. Presenting a good appearance is a much more important thing than many people imagine, and it is sometimes the secret of success. Moreover, it must be a satisfactory condition to the engineer himself and to those who employ him.

(d) In a long trip it is difficult to keep count of all small expenditures, the money gets away, and at the end of the week a 'sundry' item of \$5 or \$10 would be legitimate.

(e) Yes, certainly, in amounts of over \$50.

(f) A question for the engineer to decide. He must be assumed to be a conscientious man.

(g) A monthly statement of expenditures should be submitted if desired by the company. In any case, the engineer would do well to balance his accounts once a week, for his own satisfaction.

6. Yes. The company has a right to expect reports of progress, subject to amendment in the final report, but it should be made clear that such statements are not a final opinion.

7. An engineer had better keep out of the share market. It is dangerous to him in more ways than one.

8. Not without a specific understanding with the employer.

9. No. None whatever, except perhaps in exceptional cases.

10. The engineer should report facts exactly as he finds them. A company or investor can decide whether or not they are justified in making the investment. Of course, if the engineer is asked for a yes or no opinion, the matter assumes a different aspect. As I take it, he is usually sent into the field to ascertain technical facts, and to interpret them to his employer, leaving the decision of the investment upon the latter. In the second part of this question, the engineer should be left to his own judgment, which will be guided according to the amount of funds placed at his disposal for the purpose.

The profession of a mining engineer is eminently a respectable one, and an engineer must always be careful to maintain his dignity and self-respect. Honest and faithful service should be his motto, rather than mere money-getting. The temptations for speculation are ever present, but must be guarded against most scrupulously. If mining engineers will always strive to maintain high ideals, they will be in a position to exact large fees.

F. LYNWOOD GARRISON.

Philadelphia, October 10.

The Editor:

Sir—I take this opportunity to answer the questions appearing in your issue of October 5 as follows:

1. For a large work it is better to charge a salary of from \$300 to \$500 per month.

2. It is not necessary to have a written contract with your employers; a letter is sufficient. Get pay in advance so as not to influence the report.

3. A lump sum can be demanded in advance to cover all the expenses of the trip.

4. The company must not be charged with the equipment necessary for the work, as the engineer is supposed to have a camera, surveying and assaying instruments.

5. (a) Tips to servants are permissible, as proper accommodations cannot be had without tips. (b) The engineer is entitled to the best first-class passage on train and on shipboard, and to the best accommodations at hotels. (c) It is not right for an engineer to travel second-class and charge the company first-class, as it would weaken the value of the report, if known. (d) The expense account is to be kept in a general way. Frequent charges of 'incidentals' to cover small expenses is permissible. (e) It is best to take vouchers for large expenditures, say, over \$100.

6. It is not a good plan to send periodical reports on the progress of the investigation, giving results, such as assays, as they are obtained in the course of the work; it is better to wait until finished, and then go over the work. The company is not justified in demanding frequent periodical reports of this kind.

7. No engineer should buy shares before the report is turned in, as it tends to weaken his report. It is all right to do so afterward, but it is better to keep clear unless the company invites it.

8. It is not legitimate to take advantage of your presence in a district, to examine, and perhaps option, mining properties for yourself, as it weakens the report.

9. Do not publish in technical periodicals any description of the district visited, or of the mines included in your examination, until at least six months afterward.

10. It is expected of the engineer to say 'yes' or 'no' positively. The engineer is not justified in spending company money to clear out old drifts, unwater shafts, and open caved ground, without notifying them and receiving orders to do so.

The best method for a young engineer to adopt in order

to succeed is to buy 1,000 shares of stock in a going mine, and then make the mine pay.

ALEX. ROY.

Oakland, October 8.

The Editor:

Sir—Referring to T. S.'s list of ten questions, as published in your issue of the 5th inst., I offer the following replies, understanding that the questions are asked in reference to a long journey of uncertain length to be made by a young mining engineer to examine a moderately priced property situated in the tropics:

1. A young engineer could not ordinarily charge a fee for such a trip, and it would be better for him to undertake the work on a *per diem* or salary basis.

2. Correspondence engaging the engineer is sufficient if he is dealing with responsible parties, but all details as to his proposed charges and expenses should be clearly understood.

3. A young engineer could not be expected to finance such a trip, and could properly ask for his estimated expenses in advance.

4. A charge should be made for only such equipment as is either consumed in the work or returned to the employer.

5. (a) No charge should be made for expenditures required to satisfy special personal habits.

(b) The engineer would be entitled to such traveling and living accommodations as would be used by the average business man.

(c) Nothing should be pocketed; the employer should have the benefit of any difference between actual and estimated expenditures.

(d) Minute detail in an expense account is not necessary.

(e) Take vouchers whenever possible as a matter of business, but they need not be turned in when making final settlement unless called for by the employer.

(f) The young engineer had better secure all his information by working for it. By so conducting himself as to command confidence he can gather plenty of gossip without paying for it.

(g) Render bill at the end of the engagement.

6. Ordinarily all an employer wants is one concise and definite report, but an engineer on a salary basis should report as frequently as his employer asks him to.

7. The young engineer should keep in mind that he has the opportunity of making business connections each time he makes an examination. He should make the most of such opportunities and not be tempted to take some unfair advantage because of inside information. All information secured at the expense of a client always belongs to the client, and the engineer should not use it for private gain unless the client consents thereto.

8. When making a trip on a salary basis with all expenses paid, the engineer's time belongs to his employer; but proper recognition would undoubtedly be given an engineer who might call his employer's attention to any profitable business other than the special business in hand. However, the engineer must not assume that his employer is able to handle any other business than the business in hand, and should not give outside business any of his time unless he has first obtained the consent of his employer.

On the other hand, if the engineer is doing the work for a fee, he could properly look at and option properties for his own account, provided: First, that he has completed his mission to examine one special property and his employers are looking for no other property; second, that he rebates to his employers a proper proportion of

his traveling expenses and offers them the opportunity to participate in his options.

9. Nothing should be published without first obtaining the consent of his employer.

10. While the engineer may not be able to say 'yes' or 'no' as to the property in question, he should be able to say whether it is 'good,' 'bad,' or 'doubtful.' If good, the engineer is justified in securing all the facts and data possible; if bad, he should go to no more time or expense than absolutely necessary; and if doubtful, he should not go to any unusual expense.

F. W. B.

San Francisco, October 21.

The Editor:

Sir—From my point of view it is rather surprising that several of the questions as to professional customs should be prompted by a desire for information. The tenor of your editorial and its reference to the motto "*Noblesse oblige*" necessarily implies a line of answers in harmony with most of those given in your issue of the 19th inst. Unfortunately, there are some whose training, or rather want of training, leads them to think that money-making is the sole criterion of success, and I am afraid that it must be admitted that the adage, "Honesty is the best policy," is not true to those who have this standard; their answers to these questions, or at all events, their practice, would be the reverse of those given. When a man is in doubt as to which of two opposite courses of conduct he should follow, he may be sure that the one which needs excuses to defend it is the wrong one. "*Qui s'excuse s'accuse*," and when "business is business" is given for the reason of an action, it may generally be considered as a defense of something that his conscience condemns.

Others of the questions are matters of common sense, requiring different action in every different case. As to charging expenses I was disgusted in my early life by an associate who gave petty details of every item, but was not at all scrupulous in weightier matters, so I adopted the opposite extreme, and for about fifty years have constantly rendered lump sum bills without a single item specified, the amount being obtained by balancing cash on hand at the beginning and the end of the trip, excluding any obviously personal expenditure, and I am pleased to say that never once has my account been even commented upon.

R. B. SYMINGTON.

San Francisco, October 24.

Slag-Dams.

The Editor:

Sir—In your issue of August 17 there appeared a letter by Mr. F. M. Smith, manager of the smelter at East Helena, Montana, describing a slag-dam which I designed and built in 1898, when superintendent of that plant of the A. S. & R. Company.

As it is the only large dam of its kind of which I have any knowledge, a description of the method of construction will probably be of interest to the readers of the Press. Up to the time of its construction the water for the jackets and for general use about the works was obtained from a ditch taken out of Prickly Pear creek above the plant. As the stream was subject to sudden rises and carried down a large amount of gravel and sand, mud, and general rubbish, the ditch was frequently filled up and the small dam was often washed away. The jackets and boilers were frequently either filled with mud or short of water, and the general discomfort and

interruptions to operations made it desirable that a large storage reservoir for settling be provided.

The creek-bottom at that point is about 1,500 ft. wide and about 15 ft. lower than the general level of the fan-shaped delta of the creek, as it issues from the gorge a mile or more above the works. The delta is a glacial moraine and contains a small amount of placer gold. The slag-dump had been built out from the furnaces so that about one-third of the creek-bottom had been filled up level with the tops of the banks. I proposed to extend a slag embankment like a railway fill across the remaining two-thirds and put in a spill-way so that the flood-water could pass and use the reservoir formed above the fill for storage. This plan was carried out and the dam completed about the time I left the East Helena plant to enter the services of the Mond Nickel Co. Mr. Smith's description of the dam is the first mention I have seen of it since that time, and as it is one thing that I have built that will probably outlast the present generation, a

ahead of him, as shown in the photograph. The photograph is not quite large enough to show the sheave on the end of the rail, but the rope and the rail show as well as the stop-guards on the rail ends. The driver rode on the car to operate the foot-brake and led the horse by the bridle. When the fill reached the ends of the rails, a short length was put in farther back and the whole frame (with the sheaves attached) moved forward. This process was continued until the fill reached the creek-channel and then a concrete dam on top of sheet-piling was constructed with gates and spill-way to take off the flood-water.

In order to make the bottom of the dam tight, a trench was dug four feet wide and three feet deep in the ground in the centre line of the dam before the slag-fill was

Pouring Slag Over End of Fill.

Slag Dam, Almost Completed to the Concrete Spill-way.

description of its construction may interest posterity as well as others. The slag from the furnaces was hauled out in twin pots on a revolving trunnion supported on a narrow-gauge railway truck. These pots were of the type built by the Colorado Iron Works and were drawn by a horse.

In order to extend the fill in a direct line, it was necessary that the slag should be poured over the end of the fill. To do this it was necessary to have the horse behind the pot when it came near the end of the fill. Standard-gauge rails of about 72 lb. per yard were fitted together with iron ties for the last 60 ft. of track and on the end of one of these rails an iron sheave was fastened. Two other sheaves were placed in a horizontal position so that a $\frac{3}{4}$ -in. wire rope could pass beneath the rails and around the sheave on the end of the rails extending over the end of the fill. By this means the wire rope was so arranged that when the horse was unhitched from the front of the slag-car and the end of the rope attached, the horse could be hitched to the other end of the rope and pull the car

made. There were some old ash-dumps near the smelter that had to be cut through and a slag-fill put in place on account of the porous nature of the ashes. When completed the dam made a lake about 2,000 by 1,500 ft. and 10 ft. deep at the lower end. It will probably be used for irrigation purposes long after the smelting industry has faded away for want of ores to smelt and in the dim and distant future I can imagine some archeologist contending with geologists that it is of human origin and not a lava flow.

HIRAM W. HIXON.

Victoria Mines, Ontario, September 15.

TUNGSTEN can be mined profitably in California. For example, one mine in Kern county yielded 28 to 32 tons per month for the 12 months of 1906. This was the 'best selected,' after hand-sorting and concentration. It carried 66 to 70% tungstic acid, which at, say, \$7 per unit, made the output worth about \$15,000 per month, or \$175,000 per annum. Almost as good as a gold mine.

Notes on Tube-Mills.

In the August *Journal* of the Chemical, Metallurgical, and Mining Society of South Africa, there are some interesting observations on tube-mill practice by J. Kennedy. He insisted that the work of the tube was due to grinding, rather than impact action, saying:

I had come to the conclusion some time back that manganese liners had not been given a fair trial before being condemned, as, at the Glen Deep, the life of manganese liners was about 90 days, while at the Robinson Deep the liners lasted only about 50 days; I therefore set to work to ascertain the cause of this marked difference in life, and in endeavoring to approach as nearly as possible the real thing, that is, manganese lining, I found that by loading a glass jar with small pebbles, which had been discharged from the tube-mills, the pebbles reaching just under the neck of the jar, when lying on four rollers, and clean sand and water at 1 to 1 being added to reach just under the centre of the jar, the jar then being made to revolve; the result was just as I had anticipated. Instead of the load being raised sufficiently high to enable the pebbles to roll and tumble over one another, the load, with the exception of a few pebbles, slipped on the side of the jar while revolving.

More pebbles were then added to bring the load well up over the centre, and the jar was started again. This time, much to my satisfaction, the pebbles, with pulp clinging to them, began rolling and tumbling over one another down the inclined surface of the load, formed by the rotary motion of the jar.

It is interesting to note how the pebbles and pulp rise at the ascending side of the jar, although to all appearances the water is level to about the outflow on the descending side.

Some members might still be of the opinion that this experiment does not prove that the grinding is not done by impact, and for their benefit I should like to explain that, in this experiment, when the jar was underloaded there was scarcely any sound noticeable while the jar was revolving, but when the pebble load was increased to the point mentioned, there was the noise of the pebbles striking the liner, which coincides with S. H. Pearce's experience while the manganese liners were being tried at the Glen Deep. Mr. Pearce stated that a good deal of difference was noticed in the sound of the tube-mill when this liner was first run, inasmuch as there was an absence of rumbling which had been a feature previously. He also stated that there was a tendency for the pebbles to wear flat, and the crushing efficiency dropped considerably. Later, the rumbling occurred again, and the crushing efficiency increased. He also concluded by remarking that he supposed that there was considerable slip on the smooth surface when starting, and that later the liner had acquired a rough surface and had raised the pebbles a little higher than the smooth surface had done, which fact causes crushing to be accomplished instead of reduction by attrition. The manganese liners when discarded at the Robinson Deep were as smooth as glass, and this proved that Mr.

Pearce's supposition was incorrect. The sole cause of the absence of rumbling and the dropping of efficient grinding was, that the mill was under-loaded. An important point which appears to have been overlooked when advocating the theory of crushing by impact is that, as soon as the rolling or falling pebbles touches the water, the pulp clinging to it becomes disengaged, and the bare pebble strikes the liner, and this accounts for the rumbling referred to.

With reference to hydraulic classification, I run seventeen classifiers, five abreast in the first row, and six in the two following, and use water on all, finding it essential to do so when dealing with a big tonnage with a limited tube-mill installation.

The longest life of silex liners, 4 in. thick, I have experienced is 108 days, and a lining of local chert, 4½ in. thick, has been running for 102 days, and to all appearances will last a fortnight longer; but it seems that the days of silex and chert as liners are numbered, judging by the success attending the lining accidentally invented at the Los Estrellas mine at El Oro, Mexico,* where the inventor had lined his mill with rifle-like castings in order

Slag Dam at East Helena.

Sheet piling before concrete dam for spill-way was put in. Smelter and slag fill nearing the spillway.

to raise the pebbles nearly to the top of the mill, thus increasing the height of drop. When the mill was opened after several hours' run, it was found that the pebbles had become wedged into the rifles, and thus formed a lining of themselves. After eight months' run the wear to the casting was found to be so slight as to indicate a life of two to three years.

EXPLOSIVES IN BRAZIL.—The use of powder for war and sporting purposes is rather limited, but the use of dynamite is rapidly increasing. The imports of both in 1905 and 1906 were as follows: Powder, \$56,383 and \$43,761; dynamite and other explosives, \$139,988 and \$178,751, respectively. The powder comes from the United Kingdom and Germany, while the dynamite and other explosives, in the order of their value, come from the United Kingdom, Germany, France, and Belgium. There are difficulties in carrying on the trade in Brazil. The duty, together with special dock and other charges, is about as follows, per pound: On dynamite, 18c.; on powder, 29c. gold. The regulations require storage under isolating conditions.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

CRUSTIFICATION is a banded structure produced by successive deposition of different layers on the walls of an opening; it is often visible in filled deposits.

FOR fortifying the cyanide solution, one method is to add cyanide in crystals to the head of the zinc-boxes, in quantity sufficient to keep the solution at normal strength.

MOUNTAINS, igneous rocks, folded strata, hot springs, and ore deposits are often all connected. The zones of folding in strata lie along certain lines of weakness in the crust.

EXPERIENCE at El Oro has shown that for reducing ore to 60 mesh by wet grinding, the Huntington mill is an effective machine. For finer grinding it is not well adapted.

MOVEMENTS in veins subsequent to the formation may produce a sheeting parallel to the walls, which may have somewhat the aspect of original crustification, and may be mistaken for it. This sort of banding is called ribbon structure.

IF a quantity of water be kept in a perfectly quiet condition, it is found that its temperature can be reduced to 20° or even 15° F before congelation takes place, but at the moment when this occurs the temperature rises to 32°. Hence, the freezing-point is not constant, but the melting-point of ice is always at the same temperature, pressure being neglected.

IN general a region of flat unfolded rocks is poor in ore deposits, as for example the region lying between the Rocky Mountains and the Appalachians, as compared with the folded region lying between the Rocky Mountains and the Pacific. When ore deposits do occur in such a flat region, they will often be found to be connected with some minor disturbance.

THE principal steps in the preparation of barytes for market are hand cobbing, sorting, crushing, washing or jigging, bleaching, grinding, and pulverizing. Such associated minerals as galena, quartz, calcite, and limonite, when occurring massive or as surface stains on the barytes, can be removed largely by hand cobbing during mining; but when galena or iron stains are scattered through the material, crushing and washing may serve to clean the barytes completely. The greater portion of the material that is mined is bleached.

PLATINUM was formerly found only in placers, but in Russia several years ago the metal was found as an original constituent in peridotitic rocks, and it is in a number of such rocks in America. Platinum in peridotite rock has been reported from the Tulameen region in British Columbia, and from dark basaltic rocks of fine grain in the same country. It, therefore, seems to be confined principally to the basic rocks, and is an intimate associate of chromite, although it has been found to a less extent in silicious rocks, such as syenites.

THE characteristics by which the two kinds of asbestos may be best distinguished are the yellow-green color and oily or greasy lustre of the chrysotile and the unctuous feel of its soft, fluffy fibre, as contrasted with the white, gray, green, or brown color and harsher surface of the amphibole fibres. Attention has been called to the angular cross-section of the individual fibres in the case of the amphibole asbestos and the rounded or flattened outline

of the silky fibres of chrysotile. The chief chemical difference between the several varieties of asbestos, all of which are silicates, is the presence of water as a more important constituent in the chrysotile. By excessive heating the chrysotile may be made to lose this hydrous condition, and then the fibres become less silky and their strength is impaired.

EXPERIMENTS have been made in connection with radium in contact with the diamond, which showed that the beta rays from radium preparations had like properties to the streams of inactive electrons in a radiant matter tube. It was found, by exposing fine colorless crystals of diamond to radium bromide undisturbed for more than 12 months that the radium caused the diamonds to assume a beautiful bluish color. This color is persistent; it was affected neither by heating in strong nitric acid nor by potassium chlorate. Furthermore, the radium had communicated to the diamonds radio-active properties strong enough to affect a photographic plate; and when they were heated to a dull redness in a dark room a faint phosphorescence spread over the stone just before the color became visible.

AT Bendigo in Australia the deepest gold mining in the world is being done. At the Victoria Quartz shaft a level is being driven at 4,150 ft. At the first of this year the depth of the New Chum Railway shaft was 4,318 ft. and that of the Victoria Quartz shaft 4,254 ft. Besides these two mines there are 11 other mines at Bendigo between 3,000 and 4,000 ft. deep. The average yield of the ore mined at Bendigo is 8.9 dwt. per ton. The average cost of mining and milling per ton is about 6 dwt. All these mines are worked on a relatively small scale. The largest producer, the New Moon, only crushed 32,340 tons in 1906 (about 90 tons per day) while the average annual tonnage crushed at Bendigo mines is under 10,000. This low tonnage accounts for the high cost of mining. At the New Moon mine, where the average gold contents of the ore is 6 dwt. 5 gr., the costs, including office expenses, amounted to only \$3.42 per ton. At Ballarat the average yield of the ore mined is 5.3 dwt. per ton. Among the high-grade mines of Victoria are the Long Tunnel and the Long Tunnel Extended, both at Walhalla, where the ore in many stopes averages over an ounce gold per ton.

THERE is little doubt that many of the uses to which tin plate is applied could be quite well fulfilled by aluminum or galvanized iron, or, assuming the manufacture of such a material to be a practicable proposition, by aluminum plate—that is, iron coated with aluminum. The price of aluminum is now about that of tin and about 14 times that of tin plate, and as the specific gravity of aluminum is, roughly, one-third that of tin plate, the cost of aluminum sheet would be about four and one-half times that of tin plate of the same thickness. Therefore, before aluminum sheet can hope to compete with tin plate in the matter of price, one or both of two things must happen—a great increase in the price of tin, or a considerable lowering in the price of aluminum. The cost of tin and aluminum being about the same, there might easily be but little difference in the cost of producing the two kinds of plate, and that difference might be on either one side or the other, though it would seem probable that the cost of producing aluminum plate would necessarily be greater, owing to the higher melting point of aluminum and its ready oxidizability. As is well known, aluminum is sufficiently tenacious and malleable to replace tin plate, resists atmospheric influences well, and, whether as plate or sheet, could be employed in the manufacture of many domestic utensils and vessels.

Jigging by Hand.

Written for the MINING AND SCIENTIFIC PRESS
By ARTHUR C. NAHL.

Hand-jigs can often be effectively and advantageously used in treating dumps of low-grade material, without crushing, and with but a very small amount of water, when the material is too fine to be economically sorted by hand. Such material was found to be available in some of the dumps on the property of the Progreso Mining Co. at Triunfo, in Baja California, Mexico, and was worked at a good profit for three years with hand-jigs.

After six months of experiment, and after several single hand-jigs of different designs had been constructed, and their action studied, the design of jig which appears in Fig. 1 was gradually evolved. It was adopted as being the most serviceable and the most economically constructed. It required little or no repair except change of screens. As the drawing is to scale, little description is here necessary.

Since the drawing was made, a change has been adopted in the matter of counterbalancing. The diagram shows shoes of a large Blake crusher, bolted to the ends of the lever-frame, to balance the weight of the jig-box; but it being almost impossible to have the weights exactly equal, the lever-frame was subject to torsional strain. This, with continued jigging, soon twisted it, and threw the jig-box out of its horizontal position. A much simpler device was arranged by nailing a box of inch boards, 1 ft. wide and 11 in. high, to the back ends of the lever-frame. This had to be hung about two feet below the top of the frame, so as to clear the bottom of the chute, and braced with two straps of iron, which were fastened to the ends of the lever-frame, bent down around the counterweight-box and up again to the frame close to the bearing, and screwed to the box and frame. The two end boards of the box were long enough to be nailed to the ends of the frame. The straps of iron prevented the swinging motion from loosening the nails. The jig-box could be exactly balanced by filling the counterweight-box with rocks or scrap iron. This is the only change that has been made in the jigs, and it proved most effective in strengthening the lever-frame and preventing it from twisting and throwing the jig-box from its horizontal position.

It was found advisable to have a false bottom, with slanting sides, inside of the jig-tank, for the purpose of facilitating the discharge of hutch, at intervals, through a two-inch nipple at the bottom. We tried first to discharge the hutch at the front of the jig-tank, by means of an elbow and short piece of pipe, but, of course, this was impossible on account of choking at the elbow. So, in place of the elbow, a flange was screwed to the two-inch nipple, about two inches from the bottom of the tank. A groove three inches wide and one-quarter inch deep was cut across the face of the flange. Into the groove was fitted a movable piece of sheet iron 12 in. long by 3 in. wide, and a scant $\frac{1}{2}$ in. thick, having a 2-in. hole bored toward one end and held in place by a similar flange and a couple of bolts. This made an effective and simple hutch-discharge gate, and could be opened and closed from the front of the jig-tank. The movable piece did not have to fit very tight, for the hutch which accumulated on it kept it from leaking. To discharge the hutch, the gate is opened gradually, and it is scraped down with a shovel, and runs to launder in front of the jig-box, whence it is thrown into a wheelbarrow or one of the cars.

Though the drawing shows only two jigs together, we constructed them in units of five. We used 2 by 12 in.

plank, 24 ft. long, thus effecting an economy of space and lumber. At first we used old wagon springs for spring-boards, as can be seen in the photograph; but these were an endless source of trouble, and gave way to the simple form of board shown in the drawing. The spring-board is a most important part of the jig, and the cheapest, most satisfactory and durable kind for a five-compartment hand-jig is the one shown in the design.

The bearings used came from old cars; they were babbitted to fit a shaft of 2-in. pipe. The weight of lever-frame, jig-box, and counterweight-box holds the shaft in place in the bearings without caps.

Each jig was fed from a chute. The material was carried through the chutes in wheelbarrows. In the single jigs no chutes were used, but it would have been almost impossible to fill the boxes in the five-compartment jigs without the chutes.

It will be noted that the jig-box, when it is raised out of the water, swings under the chute, but the top of the box does not quite touch the bottom of the chute, and the weight of the counterbalance when the box is empty is held by the cross-piece on the lever-frame which rests against the top of the chute. This is an important piece of construction, for if the jig-box were allowed to hold the weight of the counterbalance, by hooking to the bottom of the chute, it would soon be strained and twisted on the hangers out of its horizontal position. It is necessary always to keep the jig-box perfectly horizontal.

The treatment of the dump was as follows: The material was sized by hand on a steel wire screen, the size of the opening being about 25 millimetres, or 1 in. What passed through was re-screened by shoveling into a 10-mesh No. 18 wire screen, at a slant of about 45°. This was done to eliminate the fine dirt which greatly interfered in cleaning the ore and made thick muddy water, which had to be changed often. As water was scarce, it was preferable to rid the material of the fine in this manner. In the rainy season, when the dump was wet and screening was impossible, everything that passed through the coarse screen was sent to the fine jigs. Both coarse and fine jigs made more hutch in the rainy season, and the results were not so good. The oversize from the inch screen was sent to the coarse jigs, and that which passed the 1-in. screen and remained on the 10-mesh went to the fine jigs. What stayed on the inch screen and would not pass a 3-in. ring was picked out by boys. It was usually waste. The coarse jigs then treated everything between three inches and one inch, and the fine jigs, between one inch and the 10 mesh. Of course it was impossible to do perfect screening in this way, so the coarse jigs received some material that could pass an inch screen, and the fine jigs received a great deal of material that could pass a 10-mesh screen.

The coarse jigs required two men on the spring-board to give sufficient motion for separation. The length of stroke was from two to three inches, and about 90 per minute. A 10-mm. screen was used. After about 200 strokes, the waste was removed from the top with a shovel and scraper and thrown into the waste-car, and the concentrate, if sufficient to warrant, was thrown into the concentrate car. If the bed of concentrate was too thin, the jig-box was re-filled without discharging. No attempt was made at jigging on a bed in the coarse jigs. Heads to these ran about 8 oz. silver; concentrate, 23 oz.; tailing, about 3½ oz. Very little hutch was made. Two men on a jig could treat from 6 to 7 tons per day in 10 hours, and concentrated five tons of material into one of concentrate. Each man was paid \$1.25 per day. The cost per ton of concentrate was \$2.75.

The fine jigs were operated by one man on a spring-

Battery of five hand lifts

Men Operating Hand-Jigs.

board at 112 strokes per minute; length of stroke, 1 in.; size of screen, 8 mesh No. 16 steel wire. The boxes were not cleaned out entirely, but two inches of concentrate was usually left as a bed, and when this was removed, some second product was used for a bed. Hutch was jigged through this bed, and considerable was made. The average material handled ranged in size from 15 mm. down to fine grit. Value of heads, 9 to 10 oz.; waste, 2.5 to 3 oz.; concentrate, 30 oz.; hutch, 16 oz. About 4 tons of this material was concentrated into 1 of concentrate and hutch, in the proportion of about 1,500 lb. concentrate and 500 lb. hutch. Each fine jig could handle about 4 tons of material per day. Wages, P1.25 per day.

Two sets of five jigs were in operation, and usually six jigs were working on coarse, and four on fine, material. Ten men and boys did the screening and filled the chutes, at an average pay of one peso. Wages have recently been raised considerably.

While operating, the jig-box was kept wholly under water. In this manner, very little splash was made and the values in hutch were higher. The dump material consisted of ores from the stopes that were thrown over the dump with the waste from the mine. The ores consisted of iron pyrite, and almost all the silver minerals in a quartz gangue. The waste was quartz schist, quartz, and some cyanite.

The advantages of hand-jigging can be summed up as follows:

1. Need of a very small amount of water.
2. Low cost of installation.
3. Facility for moving from one place to another.

The advantage of the jigs here described is the economy and simplicity of construction, use of chutes, design of spring-boards, and convenience of the cars on tracks in front of the jig-tanks.

Uranium.

The current idea that uranium ores derive their value from their content of radium is probably due to the fabulous value ascribed to radium in many publications—a value based, perhaps, upon prices paid for it as a chemical and physical curiosity, since they are not justified by any uses thus far found for it. The principal known deposits of uranium ores in this country are in Colorado, where carnotite and uraninite (or pitch-blende) furnish the product. A reduction plant near Cedar, in San Miguel county, is operating on carnotite ores running 2% or less of uranium and having also a vanadium content. Deposits of carnotite near Meeker, in Rio Blanco county, discovered in 1906, were described by Hoyt S. Gale, of the U. S. Geological Survey, in Bulletin No. 315. The uraninite, or pitch-blende is mined in the Kirk, Wood, and German mines, in Gilpin county, Colo. Small quantities of uranium have been found in the Black Hills as uranium phosphate (autunite). Other small deposits, of mineralogic interest only, have been found in Connecticut, North Carolina, Texas, and California. So far but few uses have been found for uranium ores. Experiments made with the metal as a steel-hardening material do not show that any particularly valuable qualities are added to the steel that are not given by the use of other elements that are at present cheaper. Uranium in the form of an acetate is used as an indicator in various determinations in organic chemistry, and other salts are used in iridescent glass and pottery glazes.

MOUNTAINS of erosion are not necessarily upfolds. Upfolds tend to weaken the rocks so that they are more easily washed away.

Compressed Air in Cyanidation.

In the August issue of the *Journal* of the Chemical, Metallurgical, and Mining Society of South Africa, there is an interesting note by Andrew F. Crosse on experiments with compressed air as a means of assisting the solution of gold in cyanide solutions. He stated:

For many years I have been impressed with the idea of using compressed air, produced by a 'trompe,' for assisting in the solution of gold in the cyanide process. I believe that a trompe was first used in the Pyrenees, during the Middle Ages, for iron smelting. In this district (Pilgrim's Rest) we have abundance of water-power, and I erected a small trompe on my arrival here last October.

More than half the gold here is contained in the slime, so that a high extraction from the latter is absolutely necessary. You are probably acquainted with the Pohlé pump, which is the exact opposite of the trompe, the latter being an arrangement by which compressed air is formed, by being sucked down by water and delivered under pressure, while the Pohlé pump is an arrangement by which water, or any other liquid, can be lifted, under given conditions, owing to the reduction of its specific gravity, by the admixture of air. I make use of a conical vat, with a vertical pipe in the centre of the same, through which the pulp in the vat is lifted by compressed air, supplied by the trompe, two feet above the surface of the liquid; it falls over into an outer tube and is discharged through four pipes, having their orifices tangentially arranged so as to force the pulp into a circular motion. By this means I obtain full aeration and very rapid circulation. The solution of the gold is extremely rapid, and there is no machinery of any kind, it being absolutely automatic.

As this method was very successful, I applied the same treatment, slightly modified, to the treatment of sand. The sand must be perfectly clean and free from slime, such as is obtained from the Wilfley concentrator. I have arranged a vat from which the solution drains off into an air-lift pump; this solution is circulated through the sand. After a few hours the sand is full of air bubbles, and a rapid circulation of the liquid is maintained. These air bubbles are formed owing to the cyanide solution being surcharged with air, and they are deposited on the sand, in the same way that a piece of bread, thrown into a glass of champagne, is coated with carbonic acid bubbles. I have obtained 92% extraction of the gold by this means from 6.2 dwt. tailing in 24 hours, including washing. This result is, I believe, a record.

We live in an age when the development of the material resources of civilization is progressing in a ratio without parallel. International commerce spreads apace. Every year sees a greater demand for the raw materials and products, out of which the manufacturer will, in turn, produce the articles demanded by our complex modern life. We live and work in larger buildings; we make more use of mechanical appliances; we travel more, and our traveling is more expeditious than formerly; and not we alone, but all the progressive nations. The world uses more steel, more copper, more aluminum, more paper; therefore requires more coal, more petroleum, more timber, more ores, more machinery for the getting and working of them, more trains and steamships for their transport. It requires machines that will work faster or more cheaply than the old ones to meet the increasing demands of manufacture; new fabrics, new dyes, even new foods, new and more powerful means of illumination, new methods of speaking to the ends of the earth.

To Young Men About to Become Mining Engineers.

Contributed to the MINING AND SCIENTIFIC PRESS
By COURIENAY DE KALB.

*Instead of directing your attention this evening to technical subjects, I choose to discuss, in a practical way, certain elements of success in the chief work for which your training as mining engineers is given. The function of the consulting engineer is very attractive, so dazzling sometimes in its rewards that the chief ambition of young men is to leap suddenly into that select company, only to find themselves handicapped by inexperience, and thereby doomed to failure. To aim at becoming a consulting engineer is well enough, but to become an efficient manager is equally meritorious. The profession of mining engineering enjoys a peculiar distinction; it relates to a business which is fundamental in the progress of the world. The only original sources of wealth are the products of agriculture and mining. All else is man-made; these two are fundamental, pristine, the really indispensable necessities of the human race. To be an intelligent director of such effort, to enlarge the possibilities of successful development in these fields of human endeavor, is certainly an inspiring occupation.

The first and proper aim of the young mining engineer then should be to attain the position of an efficient manager. Let force of circumstances, the renown of your proven ability to obtain practical results lead to the call which shall thereafter make of you an adviser rather than a director. There is honor enough as manager; the ascent to that level is arduous and genuine successes are few. An adequate technical preparation is to be assumed. You are acquiring that here. But experience you are not getting in the University. The magnificent laboratory equipment of our greater institutions today often tricks young men into the belief that they have obtained a ready-made experience; a sort of ready-made garment which they have donned under the impression that it is a sufficient wardrobe for the varied functions of practical life. It is a ready-made garment, and a very good one too. It clothes the nakedness of your theoretical technology, so that you may enter upon the duties of your profession without that crippling sense of shame with which the graduate of 25 years ago was obliged to face the mechanism which he had set out to govern. Moreover it has materially shortened your period of probation. Be thankful for it, but not vain of it.

The engineer today, just as in the past, must start low if he aims high. The short cut is dangerous; it involves a steeper gradient, and your wind may give out before you reach the top. A year or two spent in the commoner work of actual mucking, drilling, machine-drilling operation, timbering, hoisting, mill-repair or construction, boiler and engine tending, amalgamating, furnace feeding, converter operating, and the like, is the best possible preparation for sure and steady promotion. It enables you to learn how things are done, how much a man can do, and what he can not do; it also subjects you to the hard school of discipline, for the best training for the responsibilities of control lies through being governed. This involves absolute respect for the governing power. Do not criticise your manager; work for his interests; conceive him to all intents and purposes to be the company itself; sustain him; help to hold up his hands in absolute loyalty, trusting that he best knows what is for the company's higher interest. Criticism is easy and cheap—the very cheapest commodity. Nothing in human affairs is perfect. Every laborer about a mine or works

is able to see some imperfection, some change which he could make to better things. Let any dozen employees discuss the management, and the combined criticism of the group would argue the manager a very imbecile of incompetency. A new loading bin for stope No. 4 is needed right away; the skips are too small, and any sensible man would provide larger ones; the engine is overburdened, the engine man is sure of that; those jigs are antiquated, and an up-to-date man would put in Wilfleys; the zinc-boxes are too small and the night-solution man doesn't believe the manager ever calculated the ratio of solution-tonnage to the cubic contents of the boxes; and so it goes. But no one perceives, perhaps, that the manager is making the best of his conditions under the limitations of his exchequer. He is working for the grand economic result. He may realize the imperfections in the details more keenly than his critics, and as fast as he can he will remedy them. Trust him, and help him.

Don't seek promotion; let promotion seek you. Many managers regard it as the part of wisdom to discharge a man who clamors for advancement, and the most experienced manager will never promise nor even hint at promotion until the day when he recognizes merit by pushing the man ahead. Seek to be useful, not valuable. The man who seeks to be useful measures his achievements by the standard of excellence of work done; the other applies a monetary scale to his labor, in which his measurement may err. You will be valuable enough if you first become useful. Herein lies the great distinction between meekness and self-sufficiency. It is written, "the meek shall inherit the earth," and it is true. Meekness does not mean monkish self-abasement. It implies the quality of taking your eyes off yourself; in not exalting yourself, but in directing your attention to the honesty and perfection of your performance. The meek man lives for the glory of what he can produce, not for the glorification of himself as an officiously free-willing ego.

Good work is facilitated by composure. You may work swiftly, but do not be hurried. Find that pace at which you can work steadily without excitement, and yet swiftly enough to keep your faculties up to an efficient heat. Finally, keep your philosophy to yourself. Deal consistently in facts, and aim at practical result in a world which esteems most the man who makes his contribution square with reality rather than with theory.

Assuming that you have won your way to the top—for I insist that competent management represents the summit of the range, in spite of the existence of a few more elevated peaks—let us investigate the responsibilities, requirements, and difficulties of the manager. Upon his entry on his duties many obstacles will oppose him. For one thing you may generally count upon some dissension among the members of the board of directors. Strange and inconsistent as it may seem, there will commonly be men among them who would welcome your failure. You have been forced upon them by a dominant majority. They may not go so far as to actually interfere with you, but you may find your policies criticised, and your plans restrained. This you may set down as a reflection of the efforts at compromise and conciliation going on behind the closed doors of the directors' room. The secretary cannot tell you what these men are saying who are making the weather through which you must sail, but study his letters as a shipmaster watches his barometer, and set your course and trim your sails accordingly. At the same time your force at the mine is secretly hostile to you. Some of them may know of the dissension among the directors, and will take pleasure in supporting the minority. There may be a few loyal helpers, but for the most part

*An informal address delivered before the mining students in the University of California on October 2.

men are jealous of each other's successes, and gloat over their failures. These are difficulties on the human or psychological side if you choose, with which the manager has to contend, but which do not disturb the slumbers of his critics, the mine foreman, the mill foreman, the master mechanic, and the rest.

If you are wise the first point to which you will direct serious attention is the mine. It seldom fails that you will have been told that the mine is all right. The difficulty was somewhere else, in the amalgamation, the concentration, the cyaniding, in the roasting of the ore, in the effort to run a too silicious slag. These all may need rectification by your skill and knowledge, nevertheless after correcting patent errors in practice, and starting investigations for metallurgical betterment, subject the mine itself to a severe inquisition. Nine times out of ten you will find that serious misconceptions have been entertained concerning the size and value of the ore-bodies; that development has lagged to such a degree as to threaten embarrassment of the mine's continuous production; that the average value of ore being sent to the works is and has been higher than the average which a legitimate utilization of the available ore reserves would warrant. If suitable assay-records and proper maps exist, study these critically, and take a large number of check samples to insure safety. If necessary, thoroughly re-sample, correct surveys, and re-plot the maps of the mine. For greater convenience in watching the economic results of mining and development, lay out your mine with reference to coordinates, the origin being somewhere just outside of any possible future workings, as for example, to the southwest. Then every point on the mine plans will lie northeast, and can be defined as follows: 3 N 550 E 115 + 21, which would mean that the point in question, from which, let us say, a stope-sample has been taken, is in that horizon of the mine known as Level 3, which extends from Level 3 up to Level 2; that its coordinate is found on the plan of the mine 550 ft. north and 115 ft. east of the origin; and that it is 21 ft. vertically above Level 3. This is a simple system, and by labeling the mine samples accordingly, the assays can be recorded on cards, and filed in a card index, thus maintaining a cumulative record classified in accord with the maps, enabling the condition of any part of the mine to be instantly seen at any time.

The operation of the mine also will require critical investigation. Very often your greatest opportunities for economical reform will exist in the underground operations. Analyze your output per man, per miner, per mucker, per pound of powder, per pound of candles, etc. Get part of your data from the daily reports, and part by personal inspection. Take no man's word for anything of vital import. Find out for yourself. In all industrial activity subordinates are prone to draw a veil over imperfections in their administration, and to make difficulties, delays, and excessive costs seem unavoidable. It is your duty to rend this veil, to reveal the truth. If you have learned the rudiments of your business you will easily strip off this cover of deceit, and win respect because you cannot be fooled. See that you get a rational output in proportion to the men employed and materials used. See that your hoisting appliances are doing proper duty. If you are running more than one shift and your hoisting engine is working below capacity—a common occurrence—see if you cannot concentrate your output within one shift. It is uneconomical, other conditions remaining favorable to concentration of work, to spread your activities thus in either space or time.

Having set your mine in order, scrutinize your prime movers. Take engine indicator cards. Don't take your

engine-man's word about the cards. Take your own. Test your boilers; compare your power costs with well-known standards in terms of fuel equivalents for the two places. Test your air-compressors; your electric motors. Economize your power. Most power plants are operated carelessly and inefficiently, even when the engine-man keeps his brass glistening and his linoleum spotless, and brags about his department. Subject your power-transmission equipment to an equally searching investigation. Be sure that your shafting is in alignment, your bearing-boxes well babitted, clean, and oiled; your belts in good condition and free from slip on pulleys. Examine the mechanism of all machines. Hunt for power-losses throughout your entire works. There scarcely exists a plant in which you will not be abundantly rewarded for your pains. Don't search for curious and fancifully technical ways of showing your superiority. Drive straight for the simple fundamental things. There is the wide fertile field which most men neglect. There is where you will commonly raise your larger crop of betterments. It may be less spectacular than to tear out a quantity of costly machinery and install a new process, but its effects as shown on your balance sheet will carry comfort to that majority in the board of directors which placed you in command, and will emphasize the difference between competent and incompetent management.

Sort over your scrap-heap. At an old plant it will usually prove a mine of wealth. Then take steps to prevent undue additions to it. Under inefficient management the scrap-heap grows like a graveyard during a pestilence, and incompetency is a pestilence; it is highly contagious; it sweeps from the mine-office through all ranks, down to the shoveler on the tailing-dump. Tools become lost, buried in the dirt; pulleys, parts of machines, valves, pipe fittings, bearings, bolts, nuts, are tossed into corners until they obstruct operations, and then the roustabout wheels them to the scrap-heap. The prevention of this waste, and of the indifference which it breeds, is something of a problem. Many otherwise excellent managers fail to solve it. System alone seems not to be entirely sufficient. A well-maintained storehouse system, and a well-placed storehouse are the practical mechanisms for dealing with the matter. This entails adequate clerical aid, which is less often employed than it should be. All tools (except those constituting the listed kits of special foremen, such as those of the engine-man, mill shift-bosses, carpenter, and others), and all supplies of every kind, should be checked out and duly charged, and all 'scrap' should be brought by the roustabout to the storeroom, where serviceable material can be stored, and only the material that is completely ruined will be condemned and sent to the scrap-heap. But even this system will fail in practice, because many articles will be thrown aside and become covered up and lost. To reduce the evil, resort must be had to that spirit of neatness and order which does in fact abide in all men. You cannot develop this by commanding neatness. You must practically render untidiness impossible by making a metallurgical plant as neat and as exquisite as a modern flour mill. A liberal use of linoleum, the closing up of openings to spaces under floors, a proper provision of convenient shells and lockers for articles in common use, the application of paint to machinery, to framework, and to walls, insistence at all times upon scrupulous cleanliness, a general tidying up out-of-doors—'frills,' if you choose to call them by a hard name—will beget self-respect, and freedom from slovenliness, and will prevent waste. Intelligent application of such 'frills' costs very little, and pays not only as a device for material saving, but since cleanly surroundings promote personal cleanliness, so does that in turn

promote cheerfulness of mind, which leads to a higher class of workmanship than is possible in a place that is eternally cluttered and dirty.

I have not touched on the side of technical ameliorations. The fact is that it is not in this field that the manager who is a technical graduate usually fails. If anything, he is too keen to try to ameliorate. He feels that by virtue of being college-bred he is called upon to display his scientific attainments, and he is prone to do so in the most conspicuous place, namely, in the metallurgical department. Improve your extraction by all means. Be progressive, follow the best new leadership in practice, and cautiously blaze new trails if you can; but also apply your higher training as a technologist to the improvement of your power generation and transmission, to the increased efficiency of your compressed-air and electrical equipment, and to the multitudinous mechanical problems which bristle around the mine manager, and which you, with your training, should be able to solve accurately where the empirical workman will make only approximations with his clumsy rule-of-thumb methods.

Upon taking control of a plant, do not assume that its system of operation is either all right or all wrong. Do not express opinions, but investigate. Question every established order. Demand its reason for existence, if there be any. Do not be misled into spasmodic actions, or to the making of snap judgments. Maintain a strictly judicial attitude; collect and test your evidence, and then decide upon the best thing to do. Classify, systematize, organize. Your success in the long run will depend upon your skill in organizing and systematizing. Your science will not save the situation if you have not also these qualities of industrial generalship. But back of these lies the ability to classify, without which you cannot systematize; nor organize the human agents at your command into an effective mechanism for making your system vitally operative. Here you should possess an advantage over any but the very extraordinary empirical competitor.

Classification of the work in and around a mining plant depends, as does all classification, upon your knowledge of relationships, in this case the relationships of the multitudinous duties to be performed. You cannot evolve this out of your inner consciousness, and you cannot systematize the work until you have classified it. In the average plant there is eternal friction between the various departments. The amalgamator is squabbling with the concentrator man, the cyanide foreman has grievances against both of these, the master mechanic is at war with every other departmental head, and everybody wants the scalp of the store-clerk. There is, of course, a certain amount of conflict due to the imperfections of human nature, but one group of men in Amador county, for example, will be very similar to another group at Congress, Arizona. They will work very well if they have proper leadership, and if constant conflict occurs, it is because their duties have not been properly systemized. No matter how pretty the system may appear on paper, if it does not operate well it is because it is not founded on a true classification of duties. The friction is symptomatic. A bad system develops the bad characteristics in a body of workmen because it discourages some, and it offers an opportunity to the more aggressive to overstep their authority in an effort to keep things from going to smash at critical moments.

I knew a young engineer in the wilds of Mexico, in charge of an important mine. He was conscientious, well-trained, and an indefatigable worker, but he could not evolve a workable system. His office used to make

me think of a justice's court. He was constantly hearing complaints, but never succeeded in harmonizing the warring elements. One day the ore-train ran away, jumped the track on a curve and demolished itself in a deep *arroyo*. The alternate locomotive had just gone to shop in a bad state of dissolution, so the plant was closed down for over a month. It turned out that the locomotive engineer, who worked under orders from the master mechanic, also helped in general repair work at odd times. But the mill foreman was privileged to order out the ore-train when there was special need of ore in the bins. This absurd irregularity, incidentally, was due to lack of system in the mine, so that no approximation to a uniform mixture of ore was ever maintained. Hence the quantity of ore milled was a variable, which gave the concentrator men and the cyanide men their own peculiar troubles. On this day the bin was full at 2 p. m. The locomotive engineer was detailed to repair-work on a large pump at the lower end of the plant. The ore was soft and fed out rapidly. At 4 p. m. the mill foreman foresaw a shortage of ore for the night run, and being unable to find the locomotive engineer, he ordered the fireman and the rock-breaker man to take the train to the mine for another load. The fireman's inexperience wrecked the train. The master mechanic and the mill foreman expressed their opinions of each other and of the manager, and resigned. The entire affair, from first to last, cost the company over \$12,000 cash outlay, and the young man lost his first responsible position, with a damaged reputation.

The management of men is partly science and partly art. The science of it lies in what has just been explained—the ability to classify, systematize, organize, and this you can *learn*. The art of it consists in fact.

Set an example of industry, accuracy, honesty, respectability. Never get angry, and never swear. Seek to make yourself understood by clear incisive speech, not to make yourself impressive with bold bad language, nor with caustic humor. Be courteous and agreeable, but not too distinctly affable. I recall a manager who was worthy in many ways, but who erred on the side of excessive affability. As he passed out of the shop one day a workman remarked, "Nice little doggie; see how he wags his tail," and everybody laughed, and in fact this man ultimately failed just because he could not command respect. Do not seek to establish a reputation for being charitable or kind. Nothing is more certain to be misunderstood. Your dependants will set it down as weakness of character, and will take advantage of you. Instead of this, aim at being just. Justice is comprehensible, because it is logical. It has the force of that necessity which inheres in the relation between an effect and its cause. A manager is the representative of what we like to call a soulless corporation. It is in reality a money-making instrument. It was created for that, and for nothing else, and as such it must be administered. In your personal unofficial relations you may give play to your finer feelings, but in your managerial capacity, be the cool calculating judge, and dispense justice.

In your effort to do this you will confront the perplexities of the labor problem. It is only when you meet its organized front that you realize it as a problem. It would not be so very difficult if the problem were all on one side. You think you understand the attitude of the organization; you present what seems to be a solution, based upon the data you had to start with; when lo! you find that you have missed the point utterly. Given certain factors and their supposed relationships, why can you not state your equation and solve it? Because you put only one unknown quantity into your equation, and that is the attitude of the union, whereas you are an

unknown quantity to them, and as each party is dealing with a different unknown quantity you never get the problem stated in mutually satisfactory terms. Every conceivable expedient has been resorted to in dealing with this vexatious difficulty, but where a camp has been unionized you must depend mainly upon tact. Trade unionism has lost responsiveness to the appeal to the instinct for good and efficient performance. Both sides are doubtless to blame for the present situation, but the question of causes is not of particular interest to the man responsible for getting the work done. The concrete fact is that men are now paid, not for the amount or quality of their work, but for their *time*. It is a sad fact that with this leveling downward men have become less responsive to the influences of humanitarian efforts for their material welfare. No better service nor greater devotion to employers seems to follow from the maintenance of good clean barracks, superior food at low prices, reading rooms, swimming pools, and such accessories to agreeable living. The thing that does help, however, is to encourage to the utmost the concentration in your employ of a large proportion of married men. Build them homes, provide them with abundant water, make the conditions for their wives and children comfortable, and make your rentals nominal. This pays. Moreover, it insures you a better class of men; it helps you to restrain evil and drunkenness and rowdyism. The law that "like seeks like" will soon become apparent in the effects. You will find gathering around you those who prefer quiet orderly living; who have self-respect; and such men are always the better workers. If your camp is rowdyish, you can remedy it if you will. And among other things, you must first be the gentleman yourself.

It pays to dress up after work, even in the wilderness. I have seen camps completely reformed in character by this simple expedient. If you do it your staff will soon follow the example, if you hold their respect. Their subordinates will take the hint, and so it will spread. This makes for decency, and respectability, and all the better things that belong in their company. The end of it all is infallibly a larger figure on the right side of the ledger, for respectability in a man's personal relations is reflected in his performance of duty. Perfect gentlemanliness was a characteristic of the two most successful mine managers in the United States; they both carried it with them into the wilderness; they both gave the stamp of their great natures to the camps they developed; they both won the love and confidence of their workmen; they both maintained freedom of labor in their domains. They have shown us how to carry the standards of right and respectability into regions where most men lay aside the principles of progressive civilization. They both have given us examples of stupendous practical success; and throughout their careers they have stood as types of honorable cultured gentlemen. These men are Alexander Agassiz, who made the success of the Calumet & Hecla, and James Douglas, who did the same for the Copper Queen.

In conclusion, allow me to advert to the manager's relations to his employers. As you gain experience you will come to feel that nearly all virtues are necessary in a man to make him loyal, and you will prize it as a jewel of superior worth. Become that jewel for your own company. That is a quality which seldom fails of appreciation. So identify yourself with the company's interests that no division can be drawn between the two. Get the best results you can, and stand or fall with them. Be absolutely frank, absolutely truthful, and remember that while good news will keep, bad news will not. If you have anything disagreeable or unfortunate to tell, hit the psychological moment for telling it, and that moment is

the first one in which you can find time for writing it. If you postpone, the right moment never comes; the delay adds to your embarrassment; gives you another difficulty to explain; and in the end will either warp you into falsehood or put you in the evident position of having for a time tried to deceive. I repeat, the psychological moment for telling the truth, if it be a disagreeable truth, is the first chance you can get. If you doubt this, try it once and see!

Titanium.

Titanium, although generally spoken of as one of the rare elements, is really one of the more common ones. According to F. W. Clarke, chemist of the United States Geological Survey, it forms 0.43% of the surface rocks of the globe, and is much more plentiful than lead, zinc, copper, and other metals classed as 'common.' A great many schists and gneisses carry titanium, and it is found in appreciable quantities in clays—not only surface clays but also those that have been dredged from the sea bottom.

Many iron ores contain titanium, and ores containing 1% or more have generally been avoided by miners, owing to difficulties experienced in smelting, due to thick pasty slags; but it is claimed that when properly handled titaniferous ores give no more trouble with slags than other iron ores. It is said that steel and iron made from iron ore smelted in a blast-furnace running on the titaniferous ores of the Adirondacks took a prize at the London Exhibition in 1851. The addition of titanium to cast iron greatly increases its strength, and an alloy called ferro-titanium is now manufactured at a number of places in this country and Europe for use as an agent by which to introduce the titanium into the iron. It is believed that titanium is used by various firms to increase the tensile strength and elastic limit of steel, and although much secrecy is maintained concerning the matter, it seems probable that some steels that are imported as vanadium steels are in reality titanium steels. As titanium, unlike other metals used for the same purpose, such as vanadium, molybdenum, and tungsten, is plentiful and cheap, its successful use in steel hardening should establish a large market for it.

Several firms are now experimenting with titanium filaments in incandescent electric lamps, but the reduction of titanium to a metal is so difficult that the lamps have not yet been extensively placed on the market.

Titaniferous magnetite and titanium carbide, the titanium of which is derived from rutile, are used as electrodes in arc lamps. When one electrode is made of these substances a block of carbon is used for the other. The best known rutile deposit in this country, the one which produced the greater part of the titanium output in 1906, is at Roseland, Nelson county, Va. A few pounds were produced in Chester county, Pa., where the product is said to occur in comparatively large crystals and to be very pure.

RADIUM IN BOHEMIA.—The growing importance of radium as a therapeutic agent has led the management of the Imperial Uranium Works, in St. Joachimsthal, Bohemia, to construct a special laboratory for the industrial production of radium compounds. The uranium ores of that district contain higher percentages of this element than any other known deposits thus far investigated. The ores and the residues from the uranium extraction have hitherto been treated chiefly at Paris, where the method for isolating the minute traces of radium was perfected. There will be manifest advantages in carrying out the extraction at the place of origin.

Editorial.

SAN FRANCISCO had an earthquake, and now, a landslide. The effects of the physical and the electoral movements are equally vital; both were the expression of a condition of unrest; after both will come a period of readjustment. First came the earthquake, then the fire, now the election. Let us have peace and go to work.

THE PATIENCE of employers is occasionally tried beyond reasonable bounds by the demands of the labor-unions, led largely by foreigners who have just tasted the delights of industrial license. But there is a limit, apparently, and it is a sweet one. The cook of the steamer *Zinfandel* refused to bake jelly-rolls for the crew, so the men walked ashore at Vallejo, leaving the vessel unloaded. The officers of the union at San Francisco refused to uphold the men and sent a new crew to man the boat. Moral: Take pie when you can get it.

FINE-GRINDING has enabled the stamp-mills on the Rand to attain an extraordinarily high duty. Since tube-mills were introduced the average stamp-duty has increased steadily; in January, 1906, it was 5.06 tons; in July, 1907, it was 5.51, that is, 5.51 tons per stamp per 24 hours as an average for the whole of the Rand. The highest duty is recorded by the Glen Deep mill, where it was 7.66; at three more mills the average for the month exceeded 7 tons per stamp. At the same time the use of tube-mills has led to an increased extraction by amalgamation and an impoverishment of the concentrate—a step in the right direction, for the concentrate involves a supplementary treatment.

LETTERS FROM NEW YORK testify to the recent anxiety regarding the financial conditions. When, despite assurances from the bank authorities, depositors stand in long lines for four whole days, there is proof of a scare almost beyond reassurance. The presence of bank messengers among these depositors proved that the anxiety to extract funds was not confined to the ignorant crowd. Bankers consider the situation unprecedented and regard the present collapse of credit as the most serious within memory. Publicly they say brave things in faltering tones, but privately they confess to the immi-nence of widespread industrial depression. Here in San Francisco the haste to withdraw funds has been checked by the proclamation of holidays, and the desire to put specie in safety vaults has been hindered by the banks and trust companies. In this the authorities are right. Nothing is more anti-social at a time like this than the effort of the individual to safeguard himself, at the expense of everyone else, by withdrawing money for the purpose of hoarding it. If many were allowed to do it,

the financial system would break like an egg under a stone. Self-preservation is truly the first law of nature and of barbarism; the preservation of the welfare of the entire community is the first principle of civilization. The man who tries to grab all the coin available is the enemy of society as organized today; he is as anti-social as Rockefeller.

RECENT REFERENCES to progress at Guanajuato have prompted a protest against the inadequate credit given to the real factors that have counted most in the development of that most important Mexican mining district. We are moved thereby to state that the two elements most influential in making Guanajuato prosperous were electric power and cyanidation. The man responsible for the application of the first of these industrial factors was Mr. Leonard E. Curtis, of Colorado Springs, who organized the syndicate that underwrote the scheme and carried it to a successful conclusion with Messrs. Bryant and McElhiney. On the other hand the application of the cyanide process is due to Mr. E. M. Hamilton, now in Sonora, whose work as a pioneer in a new field of metallurgy, namely, the application of cyanidation to silver ores of a particular character, was so complete as to have proved fundamental and of permanent worth. Honor to them to whom honor is due.

PANICKY CONDITIONS no longer exist in the copper mining industry. The price of the metal has improved by reason of heavy sales in Europe and some of the big producers have unloaded the stocks that have so long menaced the market. Many mines have closed down, especially those based on 25-cent copper and others that were mere lures to speculators; a few large enterprises founded on low-grade deposits are in a bad way and the profits of the best mines have been cut in two, but there is light ahead and while recovery may be slow, it is assured. In the meantime we are glad to say that copper mining in California is in a healthy condition and despite rumors to the contrary, the important mines and smelters are in operation.

A CHICAGO PAPER called *The Mining World* undertakes to lecture our contemporary at New York concerning copper statistics. We thought that was solely our privilege. Apparently the editor of the Chicago paper is a very young man, for he refers to his two seniors, the editor at New York and the present writer, both of whom claim to be under the age limit. Reference is made to an "autocratic system in technical journalistic circles," which must be dreadful—surely a vicious circle of the least mathematical kind. We are told that the *Mining World* was "able to predict with accuracy" that the price of copper would drop just as it did, from which we infer that great wealth has befallen the readers of the *Mining World*, for to be a prophet on such matters is worth while. Although unaware of the present sources of information possessed by the Chicago paper, we do know that for a long time it published weekly the average prices of copper at New York and those prices appeared at Chicago nine days after they had been printed in *The Engineering and Mining Journal*,

and they agreed regularly to three places of decimals. No wonder they were accurate; it was a case of vaticination backwards, even more successful than the present prophetic flights of the same paper. The editor of the *Journal* at that time was so little appreciative of the compliment of having his copper prices confirmed by him of Chicago that he offered to bet with the latter that he could not produce such statistical unanimity by giving figures a week sooner, that is, before the *Journal* could reach Chicago. Hence the humor of the cool self-complacency of the *World's* comment on "autocracy in journalistic circles."

Lessons of the Crisis.

NOW that the storm has overwhelmed some of the unseaworthy craft launched during times of excitement, there is every inducement to moralize. The same cycle of events is recorded at recurrent intervals and mankind profits as little by the mistakes of the past as the son learns from the teaching of his father. Each gets his own experience, and it is a lamentably costly process. If experience were cumulative, we would be as demigods, for ours would be the inherited and transmitted knowledge of all the generations precedent. But it is not so. Each burns his own fingers to find out that fire is hot; each loses his own money in speculation to find out that greed is punishable. Lucky, and truly sane, is the man who permits one lesson to suffice.

Is it worth while to castigate the wrong-doing of a boom that is past? Yes, if such treatment teaches anything and serves to guide us in the future. For booms will come again, as surely as industrial depression comes now. Some of the happenings of the past two years have been discussed in these columns. Among them we spoke regretfully of the widening of financial responsibility on the part of men like Messrs. Cole and Ryan, insisting that even unusual executive ability becomes impotent if spread over too many enterprises, the reputation of such men becoming simply a lure for the unwary. The Greene-Cananea episode is to the point. This is a sad fiasco, the result of self-confidence and over-speculation. F. Augustus Heinze has been broken, and the bank too—a gambler's fate. He took the Senator Stewart mine in the Cœur d'Alene when it had \$15,000 profit in ore reserves and used his reputation to sell shares at New York at an initial valuation of \$2,500,000. Much in the same way Charles M. Schwab used his notoriety to sell shares in the Montgomery Shoshone and other mines in Nevada of much less worth at enormous capitalizations. Patsy Clark, of Spokane, had his Furnace Creek property selling actively at a valuation of \$4,500,000 at one time, when it consisted mainly of a few holes in the ground and strong copper stains, while Cole & Ryan bought a prospect for \$2,250,000, sold it to their friends at \$5,000,000, and pushed it to a market valuation of \$34,000,000; and while it was selling at that figure they effected a consolidation with the Greene property and passed a lot of the combined stock to their friends as a bargain at a valuation of \$60,000,000. It is hard to believe that any of these transactions were made in good

faith. They show the willingness of financiers to attach their names to a gold brick whenever money is to be made by the sale of it. The whole atmosphere of mining finance is heavy with a kind of business that enriches a few, debauches many, and impoverishes most. There is enough legitimate business for everyone; mining does not thrive on chicanery.

The Triumph of San Francisco.

SAN FRANCISCO is vindicated; she has come victoriously through a trial more severe than an earthquake, more searching than a fire. The result of the election proves that the good sense of the people will make itself felt in times of crisis, despite the shouting of demagogues, the trickeries of politicians, and the impudent leadership of a putrid press. The call to civic decency has been answered, the cause of representative government has triumphed. The people of San Francisco, the citizens of no mean city, can afford to shake hands in congratulation, and the people of this State as a whole may salute the dawn of a better day, which presages the overthrow of the influence that has so long overshadowed the fair destiny of California. We mean the Southern Pacific railway, a corrupting tyranny that for thirty years has throttled every effort at civic and industrial freedom in this Commonwealth. You can fool many of the people most of the time, because they are too busy about their own affairs, but once in a while the intelligence of a democracy is awakened by a noble purpose, and then it is irresistible as a full tide without sound or foam that sweeps all the flotsam and jetsam of the shallows of politics high and dry.

It is fine that Dr. Edward R. Taylor should be elected to the office into which he stepped at a time of stress, and it is gratifying to see the big majority given to the District Attorney. But the cause was bigger than the men, as is always the case in great movements of public opinion. San Francisco voted for municipal house-cleaning and for an end to the corruption that has defiled every one of her industrial activities for the last four or five years. The City voted for the completion of the work of the District Attorney in prosecuting the boodlers and bribers; she has endorsed her advocate, Francis J. Heney; she has honored a man of rare public spirit, Rudolph Spreckels.

The results here and at New York indicate that W. R. Hearst has brought disaster to the causes he supported. It means the end of his sinister influence in American politics. For this let us give thanks. There is reason to hope that the manhole of a sewer will be closed ere long and that the prostitution of journalism will be made unprofitable. The election here proved the utter impotency of the press. It is doubtful if any man gained from newspaper support; most of the candidates lost by it. Even some of the papers most loud-spoken for good government sold their pages to the advertisements of the opposition, and others that advocated the election of Dr. Taylor advised their readers to vote against the District Attorney, making it perfectly evident that they were

supporting the enemies of the City and the cause of corruption in high places. The press has ceased to be a power in politics even for evil, because it is insincere, when not frankly venal. The influence of the intellectually dishonest in daily journalism is on the wane. They have been found out. So much the better. There is a time coming when the community will recognize that an intelligent and fearless newspaper can exert more influence than a university and reach more people than a church. That is one of the lessons of the day.

The immediate result of the election is to restore confidence in the destiny of San Francisco. All over the world it will be known that good government has won. Locally there is now an incentive to go forward cheerfully with reconstruction. Scores of important contracts, held back by a proviso that they were to be annulled if the election went the wrong way, will now be carried out without further hesitation. The city has stood the test of earthquake, fire, and political pestilence; from each she has emerged with unconquerable spirit and undiminished hope; serenely San Francisco stands fronting a noble future, the mists are clearing, the air of the high altitudes stirs her banners, and overhead is the perfect blue of a California sky.

A Broad Apex.

IN our issue of August 17, of the current year, there was presented a brief comment upon the then state of decision on the subject of 'broad apex' and extra-lateral rights on broad lodes or bisected apexes. It was there noted that these questions were then pending for determination in the Supreme Court of the United States in the case of *Lawson v. United States Mining Company*, involving a broad vein in a limestone belt in the Bingham district of Utah. That Court handed down its decision on October 21. The matter being of great importance to the mining industry we deem it proper to publish the decision in full, as we do on page 586 of this issue.

We have prepared a diagram showing the relative position of the properties involved, which will be of material aid in reaching a correct understanding of the facts and the law applied to them. The following important principles are settled by this decision:

- (1) Where there is more than one location on a broad vein, the apex of which extends laterally over the width of two or more locations, the senior locator takes the entire width of the vein on its dip, leaving to the junior claimants only surface rights.
- (2) A failure to adverse an application for a lode patent is a waiver of any right to conflicting surface areas, but does not prevent the subsequent inquiry as to which of two claims were prior in point of time, where the underground or extra-lateral right of the respective parties becomes alone involved.
- (3) In determining the question of priority, proceedings antedating the entry and patent, for example, the date of discovery and location of the respective claims, are proper subjects of inquiry. This is not a collateral attack on the patent.

Personal.

W. M. BREWER is at Tonopah.
MARK L. REQUA is at New York.
HENRY BRATNOBER is at Seattle.
H. H. WEBB was at Cobalt lately.
E. RENSHAW BUSH is at Pittsburg.
JOHN B. FARISH is at the Fairmont hotel.
JOHN HAYS HAMMOND is at Santa Barbara.
E. A. WEINBERG has returned to Melbourne from Queensland.

H. N. O. SPICER, of London, is visiting Goldfield and Tonopah.

R. K. ESTOP is engaged in dredging work at Oroville, California.

F. F. SHARPLESS is examining a gold mine near Boise City, Idaho.

W. C. PATERSON has left Mogollon, New Mexico, and is now at Denver.

JOHN HERRON, formerly at Telluride, Colo., is now at El Oro, Mexico.

T. S. MATHIS has returned from examining mines in southern Oregon.

C. C. SMITH, of Reno, sails on November 12 on the *San Juan* for Costa Rica.

GEORGE GUNN, of Ely, was in San Francisco this week; he is now at Salt Lake.

LLEWELLYN HUMPHREYS has been examining mines in Siskiyou county, California.

D. W. SHANKS is general manager for the Rio Plata Mining Co., in Chihuahua, Mexico.

HENRY F. LEFÈVRE is at New York, on his return from Mexico. He will be at Denver shortly.

R. L. ARMIT has been appointed superintendent of the Pinguico mine, near Guanajuato, Mexico.

A. G. COLE is assistant engineer with the Pittsburg-Silver Peak Gold Mining Co., at Blair, Nevada.

JAMES T. GRIBBLE has been appointed superintendent of the Channel mine, in Nevada county, California.

GEORGE G. LYLE, of Guadalupe De Los Reyes, in Sinaloa, is investigating milling methods in Colorado.

HERBERT R. HANLEY is assistant superintendent for the Bully Hill Copper Mining & Smelting Co. at Winthrop, California.

ALFRED JAMES has been elected president of the Institution of Mining and Metallurgy. He arrived at New York by the *Lucania* on November 7.

JOHN E. ROTHWELL has returned to Denver from Inde, in Durango, Mexico, where he has been for some months installing a 100-ton cyanide plant.

H. A. HORSFALL has opened an office, as mining and mechanical engineer, at 69 Wall St., New York. He was formerly in Mexico, and was connected with the Government land surveys.

MARTIN FISHBACK and HENRY SCHMIDT, of El Paso, Texas, have formed a partnership to conduct a chemical and metallurgical laboratory, to be in charge of Mr. Schmidt, Mr. Fishback still maintaining his office as mining engineer.

THE friends of GEORGE WILSON are anxious concerning him, having no news of him for six months. He left London early this year, and is the lessee of mining lands in Russia. He was formerly in Mexico, and is a tall Scotchman, with white clipped beard. Communications addressed to the Editor will be transmitted to his friends.

Dividend.

On November 4 the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 122 of \$120,000. This makes the amount of dividends paid since January 1 \$1,860,000, and the total to date, \$9,726,000.

General Mining News.

ALASKA.

It is reported that the employees of the Hadley smelter have attached the smelter for wages. The plant has been in the hands of a receiver for over a month; he states that the men will be paid as soon as returns from the ore shipped to the Tacoma smelter can be had.—The Porcupine M. Co., near Juneau, has closed down for the winter; about 40 men work at the mine. All have left for the United States except two or three, who will remain as watchmen.—The property on which the City of Nome is built has been sold to the Sinook M. Co. Several leases have been given by the company on ground near Snake river, but beyond the city limits.—West and McNeil have left Teller for the Ears Mtn., taking an outfit with which to begin work on their tin prospects in that district.—Considerable mining will be done this year in the vicinity of Solomon; boilers have been taken to several of the claims to aid in this work.—P. A. Dickson and Paul Assmuss will soon begin operations at the Dorah bench, near the mouth of Nome river, at the place where they worked toward the end of last winter.—The Allene M. Co. intends to do considerable prospecting on their claims along Allene creek; they will also do some mining, as pay-gravel has been found on these claims. Several boilers and a large outfit have been sent to the mines and all preparations have been made for the winter work.—Considerable prospecting is predicted this winter between Cape Nome and Nome river. Nome river is now frozen over at its mouth.—The Leland dredge is still operating at Solomon; the frost has not interfered with the work as yet.—A \$600 nugget has been found on Homestake creek, which is on the east slope of the Sawtooth range and some distance below Salmon lake.—It is estimated that the output of the Fairbanks district will be larger this year than last.

ARIZONA.

COCHISE COUNTY.

A two-foot vein of copper-bearing sulphide ore has been found on one of the claims in the Ophir group, near Paradise.—The Duluth-Chiracahua Co. has two men working at the Copperopolis property doing the assessment work.

The new orebodies recently found in the Lucky Cuss and Emerald mines still look well.—All the mines at Tombstone are working with their usual forces.—The 200-ton mill of the Tombstone Consolidated M. Co. was shut down one day last week for repairs.

GILA COUNTY.

The Arizona-Colorado Co. will resume work about the end of the month. The shaft at this property is 700 ft. deep and several veins were cut in it. The lode, which the shaft cut at a depth of 150 ft., is 40 ft. wide. It is planned to sink the shaft another 100 ft., as the returns from the first and only shipment of ore from this property were quite satisfactory.

The output of the Old Dominion smelter for October was a little over 4,000,000 lb. of blistered copper, which is the record at this smelter. All five furnaces were in commission at the first of the month but, when orders were received to curtail, one furnace was discontinued and later another so that now only three furnaces are in operation. Beginning with this week the Old Dominion will work six days instead of five as was at first the intention.—The members of the Globe Miners' Union held a special meeting last Saturday and although no official information was given out it is understood that the majority voted to accept the reduction of 50c. per day provided a 6-day week was worked.

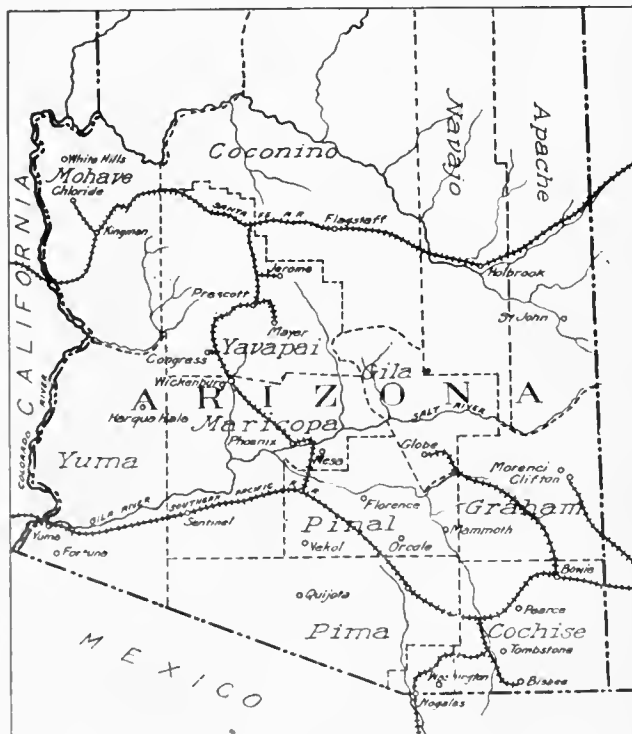

GRAHAM COUNTY.

Perry & Spence, who are working a lease on the Laura mine in Steeple Rock district, continue to ship ore to the Shannon and Copper Queen smelters. The new orebody found in the raise on the 300-ft. level is producing a good deal of shipping ore.—A number of men are working at the Mascot mine near Safford. The shaft will be sunk 50

ft. deeper.—J. F. Cleaveland has been elected president of the New York-Arizona Gold & Copper Co.—The Standard, Copper Center, and San Jose claims at Morenci are looking well; the Copper Center and Standard are shipping copper ore to the Dominion Copper Co. smelter, while the San Jose makes occasional shipments of silver-copper ore to Douglas. The aerial tramway at the Standard is working well; the ore in the lower workings at the Standard is not nearly as rich as the ore near surface.—The vein at the Buzzard Shadow claim still is looking well. This vein occurs along the contact of a porphyry dike with quartzite and is parallel to the old Buzzard Shadow vein which follows the other side of the dike.

MOHAVE COUNTY.

Work at the McKesson mine is at a standstill owing to the failure of the pump to arrive. A good vein of gold ore had been struck in the bottom of the shaft when the water-course was cut.—F. P. Andreas has made the second payment to S. A. Tyler on the purchase price of the Golden

Map of Arizona.

Eagle group of claims on Cerbat range above old Canyon station. Mr. Andreas has been working these claims for several months with quite encouraging results.—The directors of the Gold Road Co. have decided to sink the main shaft to a depth of 1,400 ft.; it is at present 800 ft. deep.—The McCracken mines have been sold to the Western Development Co. of Chicago.—The cross-cut from the bottom of the shaft at the P. K. mine in I X L basin has been in good lead ore for 8 ft., but as yet there is no sign of the other wall. H. W. Bowen is manager of this mine.

PINAL COUNTY.

The Kelvin-Calumet Co. will continue to work in spite of the low price of copper.—The Ray mine and mill has been shut down; about 300 men were working at this property.

YAVAPAI COUNTY.

The new cyanide mill at the Parker group of mines, on Turkey creek, belonging to the Buffalo-Arizona Mines Co., is working successfully. It is planned to do considerable development work at the mine this winter.

CALIFORNIA.

EL DORADO COUNTY.

The gravel recently found in the drift from the shaft in the mine belonging to the Prevolcanic Channel Gold M. Co. at Pacific is quite rich but its extent is not known. It is stated that the company prospected this property owing

to notes in one of the U. S. Geological Survey reports, which indicated that the channel was somewhere near this point. Gold-bearing gravel had already been found in one of the holes drilled near where the shaft was sunk.—The Mt. Pleasant mine and the Eagle mine, both at Grizzly Flat, have been sold. The recent purchasers of the Still-wagon are preparing to stope some ore and test it in the 5-stamp mill which is on the property.

MONO COUNTY.

Two groups of claims in the Sunny Jim district have been sold by J. W. Duval; the Florence, Masonic, Queen, Scott, Alexander, Tyler, and Hamilton claims have been sold to the Tyler Gold M. Co., while the Sunny Jim M. & M. Co. has bought the Optimo, Sunny Jim, Jupiter, Satellite, Chicago, and Missing Link claims.

NEVADA COUNTY.

The new company, which has purchased the Lincoln property, on Little creek, has begun to build a shaft-house at the property.—The 20-stamp mill at the Yuba mine, near Maybert, is running full time. Ten of the stamps are crushing ore from the Yuba mine and the other ten crush ore from the Mayflower mine. The company has decided to build two miles of new flume which will deliver water at higher head and so provide more power.

Work has begun at the Belle Union property. A drainage adit to be about 300 ft. long is being driven to catch the vein at a greater depth.—Work on the 10-stamp mill at the Ancho mine, near Graniteville, is progressing rapidly; it is expected that the mill will be finished within three weeks. The mine is developed by two adits. The longer adit, which is 700 ft. in length, is being put in shape for active work. H. W. Overmann is in charge.—The Mayflower mine at Canada hill, owned by W. H. Martin and others, has been bonded to W. G. Motley. Working on the property will begin about the first of the year. There is a 20-stamp mill on the property. The mine has not been worked for several years.

PLACER COUNTY.

(Special Correspondence.)—The 2-stamp mill for the Rubelin mine, in Last Chance ravine, has arrived and will be installed immediately.—Savage & Warden have five men at work on the Three Queens mine in Volcano canyon. They are retimbering the mine, straightening drifts, and preparing for systematic development during the winter.—Mr. Drummond is cross-cutting the old channel at Georgia Hill near Yankee Jim; the gravel is said to be of good grade.—Tom Browne is having a mill-test made on gravel from the upper channel of the Paragon mine. The lower channel at this old mine paid well in early days, and apparently the mine will again become a good producer.—The old Gaylord drift mine, about 2½ miles below Auburn, is being reopened; this mine is on the Forest Hill channel and has been mined in a small way for years, but the pay gravel has been quite spotted heretofore.

Auburn, Nov. 3.

The 10-stamp addition to the old 10-stamp mill at the Holy Cross mine on the American river, near Towle, has been completed and the mine is now ready to operate.—Work is progressing at the Hidden Treasure, Eureka, Mameluke, and Jupiter drift mines.—At the Buckeye and Slope mines 80 men are working.—The Downing drift mine, near Towle, has been bonded. It is opened by a 600-ft. adit. This mine is north of the famous Mountain Gate mine, and it is thought that the same channel goes through it.—The Big Giant Co. is cleaning out and retimbering the old adit on that property.

PLUMAS COUNTY.

The gravel at the Bellevue drift mine between La Porte and Gibsonville is yielding good returns. There are 19 men working at the mine.—The Reno men who were working the Arcadia mine, three miles north of Greenville, have given up their bond on the property owing to the present money stringency. The owner, D. M. McIntyre, has continued the cross-cut, which was being run by the Reno people, and has cut a low-grade vein eight feet wide. This cross-cut will be driven another 50 feet.

SHASTA COUNTY.

Work at the Niagara mine in the French Gulch will soon be resumed.—The Keswick furnace of the Mountain Copper Co., which has been running only a short time, has been shut down. This does not affect the main smelter of the company, which is at Martinez. The Gold Leaf mine is working a full force of men; the Milton and the Brackett mines are also working.—The ore from the Golinsky mine at Kennett is being shipped to the Guggenheim smelter at Garfield, Utah.

SIERRA COUNTY.

Soft rock has been struck in the South Fork gravel mine at Forest, and it is expected that the channel will be cut in a few days.—A contract has been let to drive a lower adit at the Australia quartz mine in Slug canyon and work has begun. Good ore has been found in the upper adit. The mine is owned by Gov. Sparks of Nevada and Richard Phelan.—The Kate Hardy mine, near Forest, has been bonded by Tyler Dudley to a San Francisco company.

TUOLUMNE COUNTY.

At the Ellen Winton mine the east drift, which was started a short time ago, is looking well. The mill is running steadily. T. J. Crowley of San Francisco is owner of the mine.—At the Kanaka mine the installation of new machinery has been commenced. The mill is not completed as yet.—The shaft at the Kennedy mine, which is now 3,100 ft. deep, is to be sunk another 200 ft. Much of the ore coming from the lower levels of this mine is said to be richer than that from the upper levels.—The lawsuit in regard to the 10-stamp mill at the Arbona mine, near Tuttletown, has been decided in favor of the Calmas company. Unwatering of the mine will begin shortly; the mill is being repaired. R. B. Lucas is superintendent.—The owners of the Pattison mine at Tuttletown have taken possession of the mine, claiming that the Pyrenees Mining Co., which had it bonded, has not lived up to the bond.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence.)—What is considered to be a good strike has recently been made by Graham & Anderson in the Columbia mine. They have a 5-in. streak which pans high in gold, and the free-gold specimens, which they have found, are encouraging. This strike was made on the 85-ft. level. The Jackson concentrating mill, of which J. G. Roberts is manager, is working night and day; it treats about 80 tons per day. An improved King screen is being installed.—The Red Elephant near Lawson has recently been started up by Pennsylvania men under the management of W. L. Shaffer. The property was operated for some time by A. E. Reynold of Denver, and has been a large producer in the past.—The Stanley Mines Co., of which Harry J. Wolf is superintendent, will soon resume, as the litigation, which has tied the mine up for the last two years, has been settled. The company will unwater the lower workings and then begin to do development at depth. It is their intention to install an up-to-date concentrating plant to treat the ore in the stopes of the upper levels. There is a large tonnage in these stopes which can be milled at a profit; much of this is cobbings from the high-grade ore which was shipped years ago. It also intends to install a new power-plant on Clear creek to utilize the water-power which the company controls. A steam-plant will also be installed in connection with the water-plant which they can operate when the water is low. The power-plant will probably develop about 1,000 hp.; the plan is to use compressed air transmission to deliver the power to the Stanley property and other mines in the vicinity. The Stanley mine is equipped with a 16 by 42 double-cylinder hoist good for 2,000 ft., which will be operated with compressed air. The air will be reheated before it enters the cylinders in order to increase the efficiency. The two-compartment incline shaft is 800 ft. deep; it is believed to be in good condition, although it has not been used for some time. The main adit has recently been retimbered and 25-lb. rails laid. The company now owns 76 lode claims, 10 placer claims, and three millsites, all

patented, which cover veins three and four claims wide for a distance of three miles along the strike. The estimated production of this mine has been about \$3,000,000. Not over 10% of the ground has been thoroughly developed. A. G. Brownlee is president.

Idaho Springs, Nov. 2.

IDAHO.

IDAHO COUNTY.

The famous Big Buffalo mine, in the Buffalo Hump district, is reported to have been sold by Charles Sweeny of Spokane to the Guggenheims. This sale includes not only the Big Buffalo but also the Vesuvius mine near Callender and a number of claims in the Buffalo Hump district, as well as all the water-rights belonging to Charles Sweeny in that district. The Big Buffalo mine has paid \$375,000 in dividends. While the surface ores yielded about 50% of the gold on the plates, in depth it becomes base; it was this

Map of Idaho.

fact which caused the shut-down of the mine in the spring of 1903. The Big Buffalo vein is 50 ft. wide on the 65-ft. level. A 10-stamp mill is on the property. It is also reported that a railroad will be built into the camp so that the ore can be shipped. The Buffalo Hump ore would make a good flux for the silicious ores of Nevada. In case a railroad is built into that district the mines about Warren will take on a new life. The base character of the ore has caused the Concord, the Crackerjack, and other mines in the Buffalo Hump district to close down, although they have good bodies of ore developed; without means of shipping the ore these mines cannot at present be worked.—Near Elk City, Leslie Belor, Herman Brown, and James Murphy have found a 6-ft. vein of good ore at a depth of 15 ft. In their Center Star group, which is an extension of the South Fork group. The vein has been exposed by open-cuts for a distance of 600 ft. The South Fork group was located last spring; it is also called the Espey mine. The crude 2-stamp mill which the owners have erected on that mine has paid them quite well this summer. On account of this success at the Espey many locations have been made in that vicinity.—Since

the Bradley people have bought the Buster mine at Elk City considerable activity has been shown at the mines in that vicinity.—The crushers at the Buster mill were run last week and considerable rock for the concrete foundations in other parts of the mill was crushed. The work on the mill is progressing rapidly, the building itself is completed and they have begun to erect the cyanide tanks. Considerable of the machinery has been already installed and it is expected that the mill will be running by the end of the month.

OWYHEE COUNTY.

The Sonnemann properties on South Mountain have shut down for the winter as it is impossible to get the necessary machinery to the mines before next spring. This property is to be operated under a working bond.—The grading for the tramway at the Banner mine has been completed. Work on the 30-ton mill has been delayed somewhat by recent rains but is progressing again. This mill will consist of Nissen stamps, concentrators, pans, and settlers. At the mine the north and south drifts from No. 2 level are developing about the same grade of ore as in No. 1 level. In the north drift on No. 4 level, which is now 600 ft. long, the ore is steadily improving. The vein at the Banner mine averages 5 ft. in width, and carries from \$5 to \$30 per ton in gold and silver. This mine is about 3,000 ft. west of the famous Trade Dollar mine in Long Gulch, near Silver City.—The Potosi mine at Silver City is looking so promising that the company is putting in the foundations for a mill which they intend to build next summer. The Potosi was operated quite successfully several years ago; at that time one mill-run of 30 tons gave \$100 per ton in gold and silver. There are three distinct veins in this property; on the Potosi vein the inclined shaft is 200 ft. deep, but the vein has been worked out by old operators above the 100-ft. level. On the 200-ft. level the ore-shoots are much longer than they were on the 100. The conditions on the 200-ft. level indicate that the ore will continue much deeper. As this 200-ft. level is deeper than the 1,700-ft. level of the Trade Dollar, this fact is quite encouraging to the district as a whole. The south drift on the Potosi vein of the 200-ft. level is 465 ft. long and carries a total length of 315 ft. of ore-shoots that vary from 6 in. to 3 ft. wide. The north drift on No. 2 level is 317 ft. long and has cut 160 ft. of ore along the Potosi vein and 60 ft. of ore along the Knickerbocker vein. The company has started to sink the main shaft 200 ft. deeper.

WASHINGTON COUNTY.

A body of rich copper ore has been found in the Boggs lease in the Peacock mine in the Seven Devils district. This orebody is 20 ft. wide and will help to greatly increase the tonnage of ore which is being shipped to the Sumpter smelter. Twenty miners are working on the lease at present, but the force is to be enlarged. At the Lockwood group G. W. Bogg has several hundred sacks of ore awaiting shipment.

MICHIGAN.

IRON COUNTY.

The Verona Co. is sinking an exploratory shaft about half a mile east of the Calumet mine in section 9. The shaft is 135 ft. deep. At a depth of 150 ft. cross-cutting will begin. The ore cut by the shaft is quite low-grade. In Atkinson township the company is sinking another shaft and installing machinery, hoisting engine, and air-compressor. The company has assumed the Coe-Piper lease on the Buchholz exploration in the Iron river district. The shaft is to be enlarged and sunk deeper. This property adjoins the Beta mine of the Mineral Mining Co.—In the Amasa district the Iroquois Iron Co. has developed a large body of low-grade ore. Boilers, hoisting engines, compressors, etc., are being installed and a shaft-house and other buildings erected.

NEVADA.

ESMERALDA COUNTY.

The out-put of the Goldfield mines for the week ending November 1 was 3,731 tons having an estimated value of \$348,600. This represents the ore sold to the samplers or treated in local mills; considerable other ore was mined but stored at the mines. The Nevada Goldfield Reduction

Co. refuses to receive any ore until the smelters are willing to settle for the ore within a reasonable time; the mines shipping direct to the smelters had to curtail or else stop shipments for a similar reason. The Western Ore Purchasing Co. continues to receive ore from those willing to wait for a settlement. The shipments were as follows: Florence L. & M. Co., 46 tons; Rogers-Goldfield Syndicate, 90; Mohawk Combination, 768; Combination mine, 50; Mohawk mine, 834; Begole lease, 390. The Combination mill treated 560; the Kinthead mill treated 140 tons of Red Top ore.—The Little Florence did not market any ore last week, only a limited amount was mined at the Mohawk, while Mohawk Jumbo, one of the largest producers, is shut down pending the settlement of the boundary dispute.—The John S. Cook & Co. bank reopened a week ago last Monday, but the Nye & Ormsby bank and the State Bank & Trust Co. remain closed. There was no run on the Cook bank; it is announced that the other banks will reopen soon.—The Goldfield Consolidated Mines Co. has declared a second monthly dividend of 10c., payable November 25. The Consolidated expects to lease the 50-stamp mill at Olinghouse near Reno. This mill has a capacity of about 250 tons per day. The shaft at the Little Florence has been completed and the station at the 500-ft. level is being cut. The vein is widening where it is developed on the 400-ft. level. The lease is producing its usual tonnage, but this is being piled on the ground instead of being shipped.—The shaft on the Albemarle property, controlled by James F. Burns of Colorado, is to be sunk to the 500-ft. level; stations will be cut every 100 ft. and the vein prospected. The cross-cut on the 100-ft. level has been cleaned out and is being driven ahead.—The shaft on the Codd lease on the St. Ives property is being sunk deeper.—A rich cross-vein, 12 to 24 in. wide, has been found at the Daisy mine at Diamondfield in a cross-cut on the 210-ft. level.—The orebody in the Rogers-Syndicate lease still looks well; stoping has begun on the 409-ft. level. The cross-cut has passed clear through the first vein on that level and is being continued to catch the parallel vein found on the 300-ft. level.

NYE COUNTY.

The Wolf mill at Manhattan began to crush ore November 2. Miners are stoping the ore on the 100-ft. level of the Manhattan Consolidated in order to supply this mill with ore.—November 1 the last spike of the Tonopah & Tidewater railroad to Beatty was driven. The new road connects at Ludlow with the Santa Fe railroad. The grades on this road are said to be quite light and the distance by rail from Tonopah to Los Angeles is shortened 90 miles.

The Montgomery Shoshone mill is now running full capacity and a high extraction is being reported. Shipments to the Salt Lake smelters continue at the rate of 30 tons per day.—Development work is being hurried at the Homestake mine. The drift on the 500-ft. level, which is in ore, is being driven ahead rapidly; the north drift on this level is 130 ft. long and the south drift 100 ft. On the 400-ft. level the north drift is 400 ft. long and the south drift 300 ft. A connection has been made from the Homestake with the King mine; this drift is 1,200 ft. long and was driven mainly for ventilation. Sinking has stopped, and instead the orebodies already discovered are being blocked out. No sulphides have appeared in the ore as yet, but some patches of sulphide ore are found occasionally in the country rock.—At the National Bank the east drift on the 3-ft. vein, which was intersected by the cross-cut on the 400-ft. level at a point 225 ft. north of the shaft, is now 40 ft. long. The ore in this vein is of good grade.—It is rumored that the Brooks intend to build a smelter at Beatty, but it is said that this depends upon whether the Brooks gain control of the Tecopa mine.

WHITE PINE COUNTY.

Work is being pushed on the Nevada Northern railroad. The laying of track on the high ore line is being carried on with as many men as can be worked. Steam-shovels are ballasting the tracks from Ely to the Star Pointer mine. This work will be completed about Jan. 1. The force on the Veteran grade is to be increased to 100 men in the next few

days. At the smelter at McGill 700 men are working. No skilled workmen have been laid off at the smelter and only what few foreign laborers as was rendered necessary owing to completion of most of the grading, etc. At the mines in Copper Flat the smaller companies are hiring all the skilled English-speaking miners and even some of the foreigners recently discharged. The first unit of the concentrator at McGill is now under roof. It is hoped that the concentrator will be ready for operation by Jan. 1. The Star Pointer mine is keeping up steam but nothing but absolutely necessary work is being done. At all the Nevada Consolidated properties this same policy is being adhered to, until the smelter is ready for operation, for all preliminary work has been done and sufficient ore to run the smelter for several years is blocked out in the mines. All the good miners, who were laid off by the Nevada Consolidated Co. last week, have gone to work at other mines in the camp.

BRITISH COLUMBIA.

BOUNDARY DISTRICT.

Two furnaces out of the battery of three are still operating at the British Columbia Co.'s smelter at Greenwood.—The electric machinery at the Crescent mine was tested last week. The mine is equipped with a 6-drill electric air-compressor, an electric hoist, and an electric fan.—The representative of F. Augustus Heinze has failed to take up the bond on the McKinley group in Franklin camp.—Steam is being kept up in one boiler at the Brooklyn mine so as to run the pumps until the final decision of the directors of the Dominion Copper Co. is made; no further word has been received from the company officials as yet.

The shipments to the smelter were as follows last week: Boundary, 33,989; Rossland, 6,938; East of Columbia river, 5,910; total, 46,867 tons.—Owing to the cutting down of the output at the Montana smelters, the shut-down of the Dominion Copper Co. smelter in the Boundary district, and the increase in the number of the men employed in the colliery and at the coke ovens in the Crow's Nest Pass, coke is coming to the smelters in good quantities and there seems little danger of a fuel famine at the smelters this winter.

On account of orders received from the head officials of the Dominion Copper Co., W. C. Thomas, the general manager, closed down the smelter at the Boundary Falls last week. This is due to the drop in the price of copper. Mr. Rundberg, the superintendent at the mine, has laid off the men employed at the Rawhide and Sunset mines; those at the Mountain Rose, Brooklyn, and Idaho had been laid off three weeks before when two of the furnaces at the smelter were blown out so as to make them into one large smelter. About 350 men have been thrown out of employment by the shut-down of the mines and smelters. During the shut-down considerable remodeling and new work will be done at the smelter.—Work has started on the foundations for the compressor, which is to be installed at the Mother Lode mine belonging to the British Columbia Copper Co. It will have a capacity of 3,400 cu. ft. per min. and will be operated by a 600-hp. electric motor.—Last week two shifts were put on at the Victoria shaft of the Granby mine and the hoist at No. 2 shaft, which has done heavy service for 10 years, is in the future to be used merely for lowering powder, tools, etc. The shaft-house at No. 1 shaft is being torn down as a needless source of danger from fire.—No ore was shipped from the Athelstan mine last week.—Diamond-drilling has begun at the Skylark mine, three miles from Phoenix.—The decrease in the ore shipments last week was due in a large part to the inability of the railroad to haul the ore during the first part of the week.

ROSSLAND DISTRICT.

Last week the ore shipments from the Rossland mines were as follows: Centre Star shipped 3,710 tons; Le Roi, 1,995; Le Roi No. 2, 560; White Bear, 140.—The shaft at the Idaho is now down 215 ft. Good ore has been found on the 400-ft. level in workings from the Centre Star mine; the Idaho is also opened up from the 1,100-ft. level of the Centre Star. The Iron Mask, the War Eagle, and the Centre Star are all looking well and the new development

The La Piamonte group of 64 pertenencias, about three-quarters of a mile north of the Greene smelter, has been bought from Frisco Arnaldo by the Calumet & Sonora Co.—A fairly rich vein, three feet wide, carrying gold, silver, and lead, has been discovered at the Hole mine, two miles southeast of Ojo de Agua. There are two shafts on the property, one 40, the other 90 ft. deep; the ore was found in the 40-ft. shaft.—The Las Chispas mine at Arizpe is troubled with a shortage of freighters. Work on the Carmen and Grindetta claims is developing some good ore. The September output of this mine was 50 tons of concentrate and 60 tons of shipping ore.

Special Correspondence.

Butte, Montana.

Wages Decreased.—Output for October.—Effects Diminished Activity.—Butte Coalition.—Davis-Daly.—Pittsburgh & Montana.—Mining Resumed.—Colusa-Leonard.—The Barnes-King Affair.

On the first of November the wages of miners were reduced from \$4 to \$3.50 per day, in accordance with the contract signed by the miners and the companies eight months ago, by which the men were to receive \$4 per day while copper remained at or above 18c. per pound, and to return to the \$3.50 scale when the price dropped below 18c. and remained below that price for 30 consecutive days. The companies voluntarily maintained the \$4 rate for more than two months after the price of copper dropped below 18c. There was some apprehension that the employees would repudiate their contracts, but the Miners Union declared its intention to abide by the terms of the contract notwithstanding the action of the Western Federation of Miners in declaring such contracts void. By reason of the curtailment of the copper output, only about a fourth of the normal working force was employed at the mines in October, and the production was in the same ratio. The total output was only about 8,376,200 lb. from 106,175 tons of ore. The total tonnage and copper production, credited to the various companies, were as follows:

Companies.	Tons of ore.	Pounds of copper.
Boston & Montana.....	16,275	1,383,375
Anaconda.....	32,550	2,441,250
Butte & Boston.....	4,650	302,250
Washoe.....	3,100	223,200
Parrot.....	3,875	232,500
Trenton.....	3,100	217,000
North Butte.....	10,850	976,500
Coalition.....	15,500	1,317,500
Original.....	12,400	992,000
Miscellaneous.....	3,875	290,625
Total.....	106,175	8,376,200

The production of the Butte Coalition Co. has been further curtailed, and 150 more men were laid off during the past week. The company had been mining about 500 tons of ore per day, but the amount has been reduced below 300 tons. A. C. Carson, general manager of the North Butte and Butte Coalition Co., predicts that copper will be selling at 18c. again before the first of the year. His opinion also is that the mines will be running full capacity again much sooner than was generally expected when the orders for curtailment were made, for with an improvement in the money situation the surplus copper will quickly vanish.—All work has been stopped on the Davis-Daly mines. The company has had considerable funds in several banks that have suspended, though it is not known whether that fact necessitated a suspension of work, the officials claiming that the treasury is in excellent condition. The last work done was in the Colorado mine, from the 1,000-ft. station of which cross-cuts were run north and south, about 100 ft. in each direction. In the north cross-cut a good sized vein was found, but it contains no ore, and the idea is that the ore has been faulted.—The shaft of the Parrot Co. has reached a depth of 2,030 ft. and cross-cutting on the 1,900 and 2,000 has been started.

The Pittsburgh & Montana Co. has resumed operations at its smelter east of the city, and mining also has been resumed. The smelter, which was built as an experimental plant for a new process, has been almost completely remodeled under the direction of Oscar Rohm, general superintendent, and the process now employed is the same as that in use at other smelters of the district.

As originally constructed it was a modification of the Garretson pyritic process, and was to treat ore without roasting or fuel. The smelter was a flat failure and the company sent its ore to the Washoe smelter. However, when the Washoe curtailed its output and refused to buy any more ore, the Pittsmtont mines had to close. Mr. Rohm then remodeled the smelter. It now has a capacity of about 150 tons of ore per day, and when running at full capacity the company will employ 150 men in the mines and smelter. Recently the company opened large bodies of high-grade copper ore on the 800 and 1,200-ft. levels, from which the smelter will be supplied. The mines had been closed for two months.—The Stewart mine, one of the Clark properties, has been shut down for a week, the shut-down having been made necessary by the fact that the west shaft was to be equipped with a steel dumping arrangement. Operations will be resumed again in a few days.—Copper ore in commercial quantities has been opened at the 600 and 800-ft. levels of the Colusa-Leonard Extension. The vein on the 600 averages nearly 11% copper, and that on the 800 runs about 3%. The ore also carries some silver. Five distinct veins have been encountered in the Colusa-Leonard shaft and cross-cuts. A drift is now being run along the vein on the 600, and a cross-cut is being driven from the other side of the shaft also. A cross-cut south from the shaft on the 800 has a 4-ft. vein of sulphide ore, much of which is mill-stuff. Eastern stockholders visited the property during the past week.

E. W. King, Speaker of the Montana House of Representatives, one of the men who unloaded the Barnes-King mine on the promoters, who sold then to the Barnes-King Development Co., has spoken and has shed some light on the deal. He contradicts the statement of the promoters that they paid \$1,200,000, and says the owners received just \$960,000 net for the property. The sum stated in the transaction was \$1,200,000, that being the capital stock of the old company, but the owners credited back to the promoters of the deal 20% of the \$1,200,000. The promoters therefore received a commission of \$240,000 from the original owners, in addition to the rake-off they took from the new company, voting themselves \$400,000 more out of the money subscribed by the stockholders of the new company. King says he still believes that the property will pay good interest on \$1,000,000. He says he so believed when he sold the mines, but that he never approved of the capitalization of the new company at \$2,000,000, and never saw any report of any person that would justify such capitalization. He declares that the promoters had full and free access to all the books and papers in any way concerning the mine, and that nothing was misrepresented to them or concealed from them, which, if true, only places the promoters in a worse light than ever. King asserts that the mines yielded good dividends on \$1,200,000 for several years and was a paying property at the time of the transfer. He thought a year's ore supply was blocked out at that time, but it is impossible for any one to say that the mine is played out or that it will be a paying property for any great period. It is a limestone formation, apt to run out at any time. King frankly says that it was because of the likelihood of the mine petering out that he was willing to sell. The recent diamond-drill explorations by the new company have disclosed one new orebody, but the ore runs but little more than \$2 per ton and would not pay to mine. Last month it cost the company \$26,000 to produce \$18,000. The new officers have not yet been able to get satisfactory reports from the former officers or from the trustees who held the money subscribed at the promotion. It is likely that suit will be brought against these trustees to recover at

least the \$400,000, which it is alleged was unlawfully diverted from the company's funds.

Toronto, Canada.

Local Taxation.—Concentration at Cobalt.—Mining Developments.—Some Rich Ore.—The Nipissing.—Shipments of Ore.—Violation of the Mining Law.

An important question as to the liability of mines to local taxation on income has been decided by the Ontario Railway & Municipal Board. The Coniagas and Buffalo mining companies were each assessed on \$100,000 as income by the town of Cobalt. They appealed on the ground that no tax should be levied on income until the amount of the capital expenditure had been realized. The Board sustained the assessment and dismissed the appeal.

The erection of several concentrating plants at Cobalt

main shaft is down 150 ft. and altogether 1,500 ft. of driving has been done. A small smelter with a capacity of 400 lb. daily is now in working order and will treat the richer ores which are free from cobalt and arsenic.

—At the Cobalt Contact the main shaft is down 112 ft. and the new shaft 50 ft. The vein on which the main shaft is sunk widened at 40-ft. depth to nearly 12 in. and has been yielding first-class ore.—A plant including an 8-drill compressor and two 7-hp. boilers, dynamos, etc., has been ordered.—At the Right of Way a first-class plant has been installed, consisting of two 100-hp. boilers, a 10-drill compressor, and double-drum 35-hp. hoist. Fifty men will be employed during the winter. A new shaft has been sunk 70 ft. from the vein and is down 85 ft., at which level a cross-cut has been started to tap the vein. At the old shaft, which was put down on the vein, an adit was run for 130 ft. and ore valued at \$120,000 taken out by hand.—The McKinley-Darragh has taken

two carloads of ore from the bottom of Cobalt Lake inside the coffer-dam.—

Operations were recently resumed at the Badger by a force of 35 men in charge of A. A. Smith, superintendent. A new shaft is being put down to work the new vein which has been stripped for a considerable distance.—Some rich ore has been extracted from vein No. 54 on the Nipissing, including several large slabs of native silver about an inch thick, one of them nearly two feet long. The yield of the Kendall vein since its discovery last May has been at the rate of about \$100,000 per month. A considerable amount of ore-stealing has been done by employees lately, and this week on a search of the bunks being made one man was arrested, a large silver slab being found in his bunk.

—A good find has been made at the Calverley-Wettlauffer, where a calcite stringer struck at 73 ft. developed a few feet further down into a rich silver-cobalt vein of 1½ inches.—Ore shipments from Cobalt for the week ending October 26 were 217 tons, from the following mines: Buffalo, 30 tons; La Rose, 154; Tretheway, 32 tons.

is expected greatly to increase the output of the camp, owing to the great accumulations on the dumps of low-grade ore, estimated at about 750,000 tons. Concentrators have been erected and are either in active operation or nearly ready at the McKinley-Darragh, Coniagas, Buffalo, and Cobalt Central properties, in addition to which there are three independent concentrators to be operated. One of these, the Muggley, has contracts for ore from the O'Brien, Townsite, Silver Queen, and Nancy Helen. The Cobalt Concentrators, Ltd., will have two plants, one on the Nipissing property and the other on the Foster. The former will treat 100 tons per day from the Nipissing mine alone. The machinery for the Nipissing concentrator is now on the ground, but installation was delayed owing to change in plans. As the result of a dry process in crushing, roasting, and smelting a proportion of the concentrate will consist of pure metallics, and the remainder will contain the ore ingredients of silver, cobalt, arsenic, and nickel, which will be sent to the smelters for further treatment.

At the Silver Queen 52 men and five drills are at work. Some 300 ft. of driving has been done on vein No. 2, having an average width of 7 in. and an average yield of 4,400 oz. silver per ton, besides carrying niccolite. The

The Black Eagle gold mine, in the Lake of the Woods district of northwestern Ontario, has been bought by an English syndicate for \$100,000, and development on a large scale will be started next spring. The shareholders of the Larder Lake Proprietary Gold Fields, Ltd., at a meeting in Toronto on Oct. 30, authorized the issue of debentures to the amount of \$100,000 at 80c. on the dollar to meet expenses. The stamp-mill is now installed and will shortly be running. Several other companies have applied to have their ore run through it for testing purposes, and the result will largely determine the future of the camp. The charge laid by the *Canadian Mining Journal* against Law & Co., mining brokers, of Toronto, of violating the mining law by issuing prospectuses of the Highland Mary Co. without giving the information required by the act for the protection of investors, came up before a police magistrate this week. T. H. Lennox, counsel for the defence, objected to the form of the information as not sufficiently specific and including too many charges. W. H. Price, Crown prosecutor, stated that they were prepared to show that the provisions of the law in regard to prospectuses and the sale of stock had been violated in every particular. The magistrate adjourned the case for a week to allow the prosecution to amend the

information. Law & Co. have brought an action for libel against the *Canadian Mining Journal*, claiming \$50,000 damages.

Salt Lake, Utah.

Dividends.—Progress at Tintic.—High-Grade Ore in the Mammoth.—Better News From Bingham.—The Yampa Smelter.—Boston Consolidated.—Shipments From Park City.—The Labor Situation.

Utah mines paid dividends during the month of October to the amount of \$955,457, the contributors and amounts being: Beck Tunnel, \$20,000; Columbus, \$56,707; Colorado, \$60,000; Grand Central, \$12,500; Horn Silver, \$20,000; May Day, \$12,000; Mammoth, \$20,000; Silver King, \$187,500; Utah, \$3,000; Uncle Sam, \$15,000; United States, \$428,750. Although the latter draws from resources outside of Utah, its principal revenue comes from the operation of its mines and smelters in the Salt Lake valley, and for that reason it is included here.

It has been learned from a reliable source that the American Mines Syndicate has cut into a nice body of ore in running a cross-cut from the Little Chief shaft to the Granite claim, upon which the syndicate holds a bond and lease. To reach the Granite claim, it has been necessary to drive the cross-cut through the Eagle & Blue Bell ground and it is in the latter that the strike has been made. The find is considered to be an important one, as it is in a portion of the Blue Bell far remote from where the company has been working.—The McKinley Co., in the Tintic district, has been installing some new equipment and is now ready to push the development of the mine. The Mammoth Mining Co. has been marketing some high-grade gold ore from its Tintic property. During the past week 30 tons were marketed which averaged close to 100 oz., while another lot of 50 tons averaged 14 oz. The Mammoth mine has the deepest shaft in the State at the present time, namely, a little over 2,200 ft. The Grand Central is down 2,100 ft. and is about to sink to the 2,500. In both mines the ore appears to persist in depth.

At Bingham, the Utah Consolidated continues to operate with a full force and there is no evidence of slowing down because of the low market for copper. This company, it is claimed, is more than paying operating expenses out of its by-products, leaving the copper as net gain. The Yampa Smelting Co. is going ahead with the repairs and enlargement of its Bingham smelter preparatory to resuming operations whenever the market conditions improve. At the mine, electric-power equipment is being installed and a small force of men is engaged in re-timbering wherever necessary. The aerial tramway is nearing completion. The Ohio Copper Co. is pushing work on its new mill at Lark, near Bingham, and if everything goes well, it will be ready early in the new year. The Ohio is a Heinze proposition; but no one here seems to believe that the operation of the mine will be impaired in the slightest through that gentleman's financial entanglements. The Boston Consolidated is shipping a small amount of ore from its sulphide mine at Bingham, but the company is not doing anything else. The construction work, which has been in progress at the new Garfield concentrating mill for nearly a year, has been halted, notwithstanding that the management could complete the plant within a few weeks. The Boston was among the first Bingham mines to curtail its output and cut down its force.—The New England Gold & Copper Co., operating at Bingham, is going ahead with development and production and conditions at this mine are about normal.

The Daly Judge Mining Co., at Park City, is installing its new electric haulage system, which will be ready for

operation in January. In the meantime ore shipments have been cut down 50%. The Silver King Coalition has been asked to curtail its production about 30% by the smelting companies, owing to a temporary congestion of lead ores at the smelters. This led to the rumor that the mine would be closed, but any action toward that end has been officially denied. Ore shipments last week came from two properties, the Silver King and Daly Judge. The former sent out 736 tons and the latter, 392 tons. The Daly West has a small force of men timbering and doing repair work in the mine; but no effort is being made to produce ore and no shipment has been made since the Park City miners' union called a strike.

It is not unlikely that there will soon be a readjustment of the wage scale in force in the several Utah mining camps. Practically all of the copper companies granted a voluntary raise of 50 cents to miners to be paid while copper sold above 18c. per lb. While none of the operators have notified their employees that there would be a return to the former scale it is probable that they will do so, unless the metal market improves in the meantime.—The new equipment at the mill of the New Stockton Mining Co. is completed. The plant will be started on two shifts during the coming week. It will handle about 150 tons per day.—An important strike of copper ore has been reported from the South Columbus mine at Alta. It is of shipping grade and appears to be in a deposit of large proportions.

Cripple Creek, Colorado.

Successful Lessees.—The Trilby Mines.—The War Eagles.—The Christmas Improving.—Annual Report of the Pharmacist.—Accidental Discovery in the Henry Adney.

The Trilby Mines Co. shows the effect of lower treatment charges by evidence of renewed activity; ore produced on company account has been leaving by regular shipments, returns from some of which have been better than 2½ oz., the average for the bulk of ore is between \$25 and \$30 per ton. Van Tilborg has resumed operations, being able, under the new rates, to ship ounce ore, on an average two cars per week. Construction of the \$10,000 cyanide mill on the property is progressing; it is expected to be in operation by February.—Work has been resumed at the Gold Sovereign; this property was handling a large tonnage at the time it closed down several months ago. On the lower levels of the mine the company has a large amount of low-grade ore blocked out; this is being held awaiting the completion of the Golden Cycle mill. Three sets of lessees are working through the main shaft, while Williams & Co. are operating through No. 3 shaft at a depth of 400 ft., shipping two carloads per week of \$30 ore.

The Pinto-Bison and the War Eagles claims, under lease to J. O. A. Carper, are profitable low-grade propositions; at a depth of 300 ft. in the War Eagles, an ore-body has been followed north of the shaft, from which shipments at the rate of six to seven carloads per month are made, this record having been kept up for months past. The vein is 3 to 4 ft. wide. On the Pinto-Bison a shoot 3 ft. wide has produced \$20 to \$30 ore for several months; occasional rich stringers have not been followed, as the desire of the lessees has been to prove up the main orebodies.—Becker & Travell, operating leases on the Christmas and Dante properties, are meeting with unusual success; on the Dante a 4-oz. shipment was made; the screenings have averaged \$40, and the coarse rock \$25, on almost daily shipments for the past month. The Christmas has shown good improvement; the lessees are sinking on ore, and regular shipments are being sent out from the Cole & George sub-lease, as well.

The annual report of the Pharmacist is out and shows encouraging conditions. The entire property is under lease to the Pharmacist Leasing Co., which has held it for the past year, an extension of lease having been granted until Oct. 12, 1909. The leasing company has completed over 1,300 ft. of development work in sinking, driving, and cross-cutting, at an expenditure of \$20,000, mostly for the purpose of proving up veins and dikes known to be productive of good ore on adjoining properties, such as the Emma quartz vein of the Isabella Co. and the Wrockloff and Pinnacle dikes. Extensions of veins from the South Burns and Shurtloff claims have been cut near the east and south lines. Several sub-lessees are carrying on extensive development work. It is expected that the property will become one of the steady shippers during the next year. W. J. Hill & Co., sub-leasing on the south end of the property through the Wrockloff shaft, last week received returns from a 17-ton car of $4\frac{1}{2}$ oz.; two other shipments assayed around one ounce.—The Cresson company sent 15 sacks of high-grade ore to a local sampler; this is expected to return \$1 per pound, the total weight approximating 1,500 lb. The property is now operated entirely on company account, the holdings of the Union Leasing Co. having been recently taken over.

The Henry Adney, one of the best producers in the camp, and the scene of many rich strikes in the past few months, has another strike of great promise, not the least interesting part of it being the fact of discovery by accident. A cave occurring on the 550-ft. level exposed ore that gave returns of better than 4 oz.; the ore-shoot now being broken is more than five feet across.

Goldfield, Nevada.

Effect of Financial Conditions.—Smelters Slow in Payments.—New Railroad.—The Rawhide District.—Output of Goldfield Mines.—Recent Dividends.—General Conditions.

The financial distress of the last few weeks has been keenly felt in Goldfield and as a consequence, operations on several leases have been temporarily stopped. The output on others has been curtailed, owing to the attitude of the smelters, which insist on 90 days leeway in settlement of ore purchased. Little Florence is not shipping while the present smelter situation exists, but is piling up \$300 ore on the dump at the rate of about 60 tons per day. The Goldfield Consolidated has not shipped to the smelters for several days, but is treating over 60 tons per day at the Combination and Kinkead mills. Mr. Kirby, superintendent of the Combination mill, made an examination of the Olinghouse mill at Wadsworth, with a view to shipping part of the Consolidated ore there for treatment, but his report was unfavorable. The cost of putting the mill in shape would be approximately \$15,000 and require three months, which made the plan impracticable. The Las Vegas & Tonopah railroad, which has just been completed into Goldfield, will soon accept ore shipments, and it is reported at a lower rate than was formerly paid. These shipments will go directly to the smelters at Salt Lake City.

The machinery for the Florence mill was shipped from Denver nearly two months ago and is expected soon. The building is practically finished and but a short time will be required to put it in condition for work.—Samples of ore from Rawhide have recently been received by local assayers, and have showed gold up to \$10,000 per ton. A town is fast springing up and it is reported that 85 leases are in operation. Several Goldfield miners and business men, who have lately returned from that district, are enthusiastic over the surface showings and predict one of the best camps in the State.

Rawhide is near the boundary line of Esmeralda and Nye counties, and it is not yet determined in which county it lies. Owing to the closing of several of the Goldfield properties, many of the idle miners are going to the new camp.

The output of Goldfield mines for the week ending November 3 was:

	Tons.	Value.
Mohawk	834	\$125,000
Mohawk-Combination	768	53,700
Begole lease	390	29,000
Rogers syndicate	90	9,000
Florence	46	4,600
Combination mill	560	39,200

The smelters have made a rule requiring 45 days in settlement for ores purchased. As it takes about 30 days

Map of the New Mining Districts of Nevada and California.

for ore to reach the smelters after shipment from the local samplers, the latter have to wait from 70 to 90 days to get their money from the smelting companies. The ore-purchasing companies cannot pay for the ore in advance of their own settlement with the smelters because the banks are not now in a position to afford the usual facilities. This has upset the ore market, and has compelled the samplers, who act as middlemen, to decline the purchase of ores except those running above \$60 per ton, as the smelters are only willing to take such material, finding it necessary to cut down on the quantity of lower-grade ore heretofore received. It is stated that the Western smelters can handle weekly about 3,000 tons of the silicious ores produced by this district and until the larger mines get their own mills in operation, the realization of profits is likely to be hindered. The Consolidated Co. has 139 cars in transit between Goldfield and the sampler at Millers. While the men in the stopes have been laid off, the Mohawk shaft is still being sunk and the winze below the 450-ft. level is being continued. During the month of October this district distributed \$661,000 in dividends, of which \$350,000 was paid by the Goldfield Consoli-

dated, \$120,000 by the Mohawk Jumbo, \$100,000 by the Little Florence, and \$91,000 by the Frances Mohawk. The Consolidated has announced monthly dividends, but it is possible that the payment of them may be hindered by the difficulty in getting settlement for the ore produced. In the meanwhile, the lower-grade ore is being treated at the Combination and Kinthead mills. The closing down of a large number of wild-cats has tended to improve the labor market and to lessen the likelihood of strikes among the workmen.

[Note.—The position of the smelting companies is not as unreasonable as it is made to appear by some of the mine-owners. At the present time it takes from 60 to 90 days to get base bullion from the local smelter to the Eastern refinery, this delay being due to congestion of traffic and lack of cars on the railroads. The Selby smelter can treat about 700 tons per month of silicious ore. At the present time it is glutted with such material, having received 2,000 tons from Goldfield alone in 22 days. This ore averaged three ounces of gold per ton and is what is called 'low-grade' ore at Goldfield. Lately, the rule has been made to receive only ore richer than $3\frac{1}{2}$ oz., there being a better margin on the richer ore than on the poorer. It may also be noted that the Selby smelter is hampered by inability to roast the sulphide ore which would otherwise be mixed with the Nevada silicious output. Owing to the trouble made by the farmers of Solano county, it has been deemed advisable to divert most of the sulphide ore to Everett and Tacoma. We understand that the Salt Lake smelters are loaded up with silicious material, and that from 200 to 300 tons per day is sent to Denver from Nevada.—Editor.]

Denver, Colorado.

Stimulus to Gold Mining.—The Coal Strike at Colorado Springs.—An Adjustment Likely.—The Golden Cycle Mill.—Experimental Work.

Since the unprecedented drop in the price of copper the attention of mining men and promoters has been directed toward gold mining. Operations at Cripple Creek are showing the result to a marked degree. Increased activity is reported at almost every mine. The reduced transportation and treatment charges, coupled with the influx of experienced miners, indicate an increased tonnage from this famous camp. Several of the mines closed down when the Golden Cycle mill was burned, and have been waiting for that mill to be rebuilt. These mines are now taking advantage of the reduced rates and resuming mining operations. The Trilby Mining Co. has its new cyanide mill and roaster well under construction. The directors of the Colorado Zinc & Chemical Co. held a meeting at Denver on October 25, and decided to suspend operations and close up the affairs of the company. For the past two years the company has been trying to develop a new process for separating zinc ores in its plant at Utah Junction, just outside of Denver. They have failed to make their process a commercial success. At the annual meeting of the stockholders of the Colorado Fuel & Iron Co., held at Denver, Oct. 22, Z. M. Bowers, of Cleveland, Ohio, was elected to succeed R. C. Clowry, of New York, who resigned as a director of the company.

The local coal strike at Colorado Springs, which has been worrying everybody concerned for the past week, seems to be nearing a settlement. Alex. Swanson, Deputy State Labor Commissioner, accompanied by George A. Hally, president of the State Federation of Labor, spent Friday at Colorado Springs investigating the causes that precipitated the strike. Although their presence did not materially affect the attitude of the

strikers and operators, yet it served to bring the questions at issue clearly before the public. The miners demand check-weighmen at the mines, an eight-hour day, an increase in the rate of wages paid to pick-men and machine-men, and the recognition of the union. This last demand for recognition seems to be the real point at issue. The operators do not feel that they can agree to this as it would mean the discharge of the men who have stuck by them during the present strike. There was some complaint that the striking miners had not been paid in full. This is now understood to be merely a business formality. The striking miners have been given ten days' notice to leave the company houses and the balance on their wages is simply held to cover the rent. Thus far the strike has been without violence and the local authorities expect no trouble. The Patterson mine and the mine of the Monument Valley Coal Co. are working under union conditions. As both sides seem willing to look at the matter sensibly, it will doubtless be adjusted in the near future.

The debris of the Golden Cycle mill is being removed rapidly. About 225 men are employed in the work of clearing the ground to make room for new buildings.

A Part of Colorado.

The roaster building is being constructed of iron and steel and will be as near fire-proof as it is possible to make it. This building, it is estimated, will be completed in about 10 days and the roasters installed. Four new duplex Edwards furnaces of 100 tons capacity each will take the place of the old furnaces, which were erected a number of years ago. About 900 tons of scrap iron has been disposed of to the Colorado Fuel & Iron Co. and 200 tons to a local concern in Colorado Springs. These figures give an idea how much material has been handled since the fire, which occurred on August 7. This does not include the number of tons of charred wood and ore that had to be handled. Besides the 225 men, 60 to 75 teams are employed in hauling sand, gravel, etc., as well as excavating for the buildings. Should good weather prevail until Christmas, the management expects to be operating a portion, if not all, of their furnaces. The cyanide plant, which was not destroyed by the fire, is at present handling the old tailing-dump. Franz Cazin is

designing the plans for the plant and C. W. MacArthur has charge of construction work.— A large amount of experimental work is being done at the Portland mill with the hope of improving the present method.

Johannesburg.

A Regrettable Incident.—Riotous Coolies.—Repatriation.—Kaffir Labor.—The Unemployed and the Tin Mines.—Position of the Boer Government.

A rather serious affair occurred at the Wit Deep mine last week, among the Chinese. Quite a number of the coolies had finished their three years' service and were expecting to leave for China this week. The management, however, decided to take advantage of a clause in the Importation Ordinance, which states that coolies have

again for three years; in fact, numerous coolies have come to the compound managers and offered them large sums of money for the privilege of remaining on the Rand. This fact gives the lie direct to those irresponsible individuals in England who are so fond of stating that the coolies are down-trodden, practically slaves, and are eager to escape from the slavery of the Rand. Since the coolies have to go, most managers are glad to get rid of them as quickly as possible, after their time is up. For a month or so before their departure, the coolies get very slack, and require a lot of driving to do as much work as formerly.

It is satisfactory to note that as yet there has been no trouble in getting sufficient Kaffirs to replace the departing coolies. The class of Kaffir coming to work just now is excellent. Many of them have worked on mines before. Unfortunately most of the Kaffirs will not sign for more than six months. At the end of that period they will return to their kraals and do nothing for a year or eighteen months. The statement that to replace the 50,000 Chinese now at work will require about 150,000 Kaffirs is not far out, when one remembers the short period of service of the black man. No great trouble is expected with labor this year, but in a year or eighteen months, when the majority of the coolies have departed, and the Kaffirs realize that they have the monopoly of the labor market, then the mines will feel the pinch.

A start has been made in solving the problem of the white unemployed. At the present time there are about 525 white men at work for the municipality of Johannesburg, on road-making and the new drainage scheme for the city. The wage is \$1.21 per day, but wherever practicable the men are put on piece-work. The average earned is not much over \$1.21, but small gangs are making as much as \$2.45 per day. The men have to work very hard for this wage, which at the ordinary prices in Johannesburg means a bare living. But the severe depression is teaching the community that men can be boarded for \$14.50 per month, as against \$30 which is the price generally charged. By some co-operative scheme it is hoped that the small pay received by the white municipal workers, will be made to go as far as possible. All kinds of white men are seen at work on the streets. The majority are young Afrikaners, but a number are men who have seen better days in the Transvaal, speculators, clerks, etc. To these men the work is severe, but it is hoped that in a little while their muscles will be toughened, and that they will be able to earn the maximum pay. As their more fortunate pals pass the workers on the street, on their way to business or the mines, they give them a cheery greeting, and by look and word express their admiration of men who notwithstanding their inexperience of manual labor are determined to toil for their daily bread rather than accept public charity.

A start has been made by the Government with their scheme of working the tin deposits with the white unemployed. Considerable anxiety concerning the feasibility of the scheme is being expressed by men who know. The Government had more direct ways of helping the unemployed. It would have been a simple matter to put the out-of-works on the Premier diamond mine, or on railroad construction. As it is, 25 or 30 men have been sent up to the tin fields. With the best of luck it will take some time to prepare for the hundreds of white men seeking employment. This tin scheme is a case of "heads I win, tails you loose," as far as the Government is concerned. Even if the experiment is a fiasco, and huge sums of money are wasted, the Boers will not suffer, for most of the taxes are paid by the industrial communities. All that will be necessary, if more money is required, will be to squeeze Johannesburg a bit more.

Map of the African Goldfields.

to work out their unlawful absence if required to do so. For instance, if a Chinaman is sent to jail for one year he can be forced to remain on the mine for another twelve months to make up for this period. The coolies objected to working out their time and refused to leave their quarters. The police were called in, and warned the coolies that all who refused to go to work would be arrested. The presence of the police seemed to infuriate the coolies, and seizing what rude weapons they could find, they cried out that they wanted to fight. Bricks, sticks, and stones were hurled at the police, who were at last ordered to fire on the coolies, with light shot. The order was given to fire low. A large number of coolies were brought down on the first volley, but this action of the police cowed the Chinese. The wounded were taken to the mine hospital, where one of them died. The incident was a most regrettable one, and will have a bad impression in China, where the people will say that in South Africa the coolies are shot down after finishing their three years' service.

Some friction is being occasioned over the repatriation of the Chinese, but there is not as much trouble as was expected. Many of the coolies are very averse to leaving the Rand, and declare they should be allowed to exercise the right given them in their original agreement, to sign

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

A Sampler Wanted.

The Editor :

Sir—Where can a spiral sampler for wet sand be obtained? I have made them from round $\frac{3}{4}$ -in. iron, with flat iron, $\frac{1}{8}$ by 2 in. wound about it, spirally, forming a screw 2 in. diam. and 3 ft. long, with the flat iron brazed to the round iron. The lower end was sawed off square and the upper end, with 18 in. of $\frac{3}{4}$ -in. round iron extending beyond the screw, was welded to heavier iron having a handle like a ship's augur. This did good work, but in the hands of careless men the brazing, imperfectly done, became loosened.

Does any dealer in cyanide supplies make such sampling augurs? Let him advertise his wares. Can your readers, including dealers, supply the information?

C. Y. KNIGHT.

[Will Mr. Knight send his address?—Editor.]

A Suggestion to Road Supervisors.

The Editor :

Sir—While making the trip from Ouray to Telluride by way of Sneffels and the Virginus mine a few weeks ago I became thoroughly impressed with the idea that sign-boards should be placed along the trails for the use of strangers who are not familiar with the country, and who are more than likely to take the wrong trail. Before leaving the Revenue mill I made inquiries as to the road to take, and was given to understand by parties who were familiar with the route that it would be impossible for me to go wrong. As luck would have it, I did not go wrong, but more than once I came to the parting of the ways and was undecided which to take, as both were more or less traveled. Fortunately, I took the lower or right-hand trail and came out all right, although below the Virginus instead of on a level with it. At the Virginus I made inquiry as to the route to take to get over to Telluride and was told that the trail was good, as only a few days before parties had gone over with horses and that it would be impossible to miss the way and there was but one gap to get through. After reaching the little mesa above the Virginus I discovered a number of gaps which looked about the same and through which a man and beast could go, but the good trail was missing, it having snowed the day before and filled up the tracks completely. Again fortune smiled on me, and I gained the summit and found I was on the right road, but no signs of a trail on the Ouray side until I had reached the gap. I could then see buildings in the distance to the left, which I took to be the Tomboy mill. On the Telluride side the trail was in good shape and easy to follow and in a short time I was down to some of the workings of the Smuggler Union. Men who are accustomed to making the trip from Telluride to Ouray and other points and who have made it several times cannot fail to realize how a stranger can get off the trail.

In September a couple of years ago I made the trip from Ouray to Lake City by way of Engineer Mtn., and before reaching the summit I found myself lost and in a blinding blizzard. I found a cabin and took possession. It happened to be the residence of some miner or prospector who was away from home at the time. In the cabin I found plenty of food and a place to sleep, so I did not suffer. On top of the continental divide in a snow-

storm, lost, and without matches, with night drawing on, was a serious matter. The next morning the storm had abated and I decided to try my luck on one of the trails. Perhaps a couple of miles down the hill I found a cabin and an old prospector who kindly directed me to the trail leading down past Rose's cabin and to Lake City. "Do you see that saddle in the mountain?" he inquired, and upon assuring him that I did, he replied: "That is where you want to go through to get over on the Lake City side." I explained to him that I had stayed over night within a few rods of that same gap and had just come from there. However, after partaking of his beans, bacon, and coffee, I started out for the 'saddle' in the mountain. After floundering around in the snow and over the bogs for some time, I reached the 'saddle' which I had left a few hours before and proceeded to Rose's cabin, where I procured dinner about 2 P. M. At that time I was of the opinion that trails in the mountains as well as the desert should be supplied with sign-boards pointing the direction to certain places, especially where human habitation is scarce and uncertain. They would save the stranger, and perhaps others, a good deal of anxiety as well as the loss of time in doubling back after he finds he is on the wrong road.

It would seem to me that counties like San Miguel, Ouray, San Juan, and the Hinsdale should see that these signs are provided and kept in repair.

E. MOORE.

Denver, November 2.

Ore Deposition.

The Editor :

Sir—Your valuable remarks on the deposition of ore and the timely observations of Mr. Winchell have established a new high-water mark in the tide of information, which, we all hope, will some day rise high enough to float away all our ignorance concerning this matter. As every little observation of fact helps to increase the sum total of our knowledge, I will mention two phenomena (the Editor says when we don't understand a thing we call it a 'phenomenon') that came under my observation.

In 1904 I examined a number of mines and prospects along the coast of British Columbia, and I noticed the same conditions mentioned by Horace V. Winchell (MINING AND SCIENTIFIC PRESS, July 13). In that very moist climate and in a country that has been lately scored off by glaciers, we find totally different conditions from those prevalent on, for instance, the desert of Arizona. There is little or no iron cap on heavy sulphide veins and consequently little ore of secondary origin except as hereinafter mentioned. The sulphides are found close to the surface. I noticed, however, that, close to the surface, pyrrhotite was generally to be found instead of pyrite. Magnetite of a very hard and dense variety is common, and on Texada island it has been developed to such a great depth (850 ft. if I remember correctly) that it would seem conclusively proved that the magnetite is not in any way related to the recent alteration of the sulphides. It is, of course, entirely possible that the veins have undergone two periods of mineralization, and that the magnetite is an alteration product of an earlier mineralization, which weathered under altogether different conditions to those now existing, or it may be that the magnetite is a primary mineral. The question naturally presents itself, could an oxide such as magnetite, and a sulphide such as pyrite, deposit from one and the same solution? I don't think they could, but am not sufficiently up in my chemistry to speak definitely. One of the properties I examined at this time was a large contact between lime and felsite situated at the north end

of Vancouver Island. There was a narrow band of magnetite in the centre of the mineralized matter, which contained some chalcopyrite. The balance of the huge contact vein was made up of alternating bands of pyrrhotite, altered country rock, and quartz. The pyrrhotite appeared practically at the surface, although there was partial oxidation to a depth of 20 ft. (the deepest hole on the property). Near the limestone edge there was considerable oxidation and some caves had been formed by the eating away of channels in the lime by the acid products of decomposition. All this pyrrhotite ran a trace in copper and a few cents in gold and silver. I had always thought that when the sulphide zone was reached, the copper content was practically settled, that is, that there was no reason to believe that a barren sulphide vein at surface would be anything but a barren sulphide vein at depth. I supposed that (although there had evidently been partial oxidation) what sulphides were left were a fair representation of the sulphides which would be found below. In this I appear to have been wrong, for subsequently three shafts were sunk on the outcrop, and at the depth of 30 to 40 ft., each one of them came into ore running from 1 to $1\frac{1}{2}\%$ copper; also a great deal of water was encountered. It is correct to say that I did not go back and sample these shafts myself, but I have no doubt of the truth of the reports. Now these facts would indicate that in those wet countries a partial oxidation may occur accompanied by a selective action and that copper pyrite yields more readily to oxidizing influences than the sulphides of iron. Of course I do not mean that this is a proved fact, but this particular deposit suggests that something of that sort may occur. In this particular case the slight increase in copper content was immaterial from a commercial standpoint; but one can readily imagine a case where an increase of one or two per cent in copper might be a very important matter. In examining mines in wet countries it might be well to consider the possibility of selective leaching.

About the same time I examined a gold vein in northern California; it was a quartz vein which was remarkably persistent in strike. The quartz had a honeycomb structure showing that in the sulphide zone it carried considerable iron pyrite. It was low-grade, however, except in spots. All the workings were in the oxidized zone. One of the peculiarities of the vein was that the iron oxidized to a gelatinous hydroxide instead of to an oxide. In some places in the vein this rule had not been followed, and there were bunches of vein-matter where the cavities in the quartz contained hematite. There were other bunches where the pyrite was unoxidized. These bunches of hematite ore and of pyrite ore always assayed more than the leached out quartz. In the latter the cavities contained only the dusty brown powder which is characteristic of an ore that has oxidized to hydroxide. The manager was a bright fellow and he maintained very stoutly that the hydroxide leached away and took the gold with it. I laughed frankly at this theory and asked him if he was trying to butt into the class of old prospectors who harp on the theory that all they need is depth, but who really are more eager to explore the depth of the tenderfoot's pocketbook, than they are to go deep on their claims. It is well known that gold veins are generally richer at the surface than anywhere else. This is because gold is the most inert element known to chemistry, so the other minerals leaching away leave more gold to the ton, although probably not more to the cubic yard. The manager maintained his theory so stoutly, however, that it set me to thinking to devise some method of proving or disproving the theory and as I recalled seeing some tiny streams of water, thick with this gelatinous hydroxide, trickling down the breast of

the lower tunnel I suggested that if the gold really was being kidnapped by the hydroxide we could catch the thief in the act. Accordingly we got a lot of coal-oil cans and fashioned some spouts of tin and caught a lot of this brownish water. I then strained it through a cheesecloth and evaporated to dryness and had the residue assayed. It ran \$19 in gold. Now this result figured back on the average loss in weight between the hematite quartz and the honeycomb quartz did not account for the average difference in value between these two classes of ore. It did show, however, that where a vein has oxidized to a hydroxide it is possible that some of the gold may have been carried away from the oxidized ore. I know of no chemical solution of gold that would exist in a fully oxidized solution, so the idea has suggested itself that possibly the gold was mechanically entangled in the gelatinous stuff. Gold, as we know, exists in iron pyrite in some form in which it will not amalgamate and it is supposed to exist as a sulphide. In any case, the decomposition of the pyrite undoubtedly leaves it in a state of extremely fine subdivision, probably in an allotropic form (a bronze-colored powder). In this form one can readily imagine that any gelatinous substance might entangle and convey considerable quantities of it.

GEO. J. BANCROFT.

Denver, October 11.

Professional Customs.

[The questions to which reference is made in these letters will be found in our issues of October 5 and 12.—Editor.]

The Editor:

Sir—As one of the younger generation, though well past the stage of my first examination, I submit the following as constituting my answers to the questions propounded by T. S. in your issue of the 5th inst. As intimated by T. S., his questions are rather ambiguous and must of necessity be answered in a general way. For my own purposes and for those of the "younger generation" generally, I hope that the questions will be answered in your columns by engineers of greater experience than mine.

1. On a protracted examination, of say one month or longer in duration, but with an understood limit, a fee; of comparatively short duration, or where engaging on a piece of work of indefinite duration, a salary basis.

2. In my opinion this would altogether depend upon for whom the work was being done; if for strangers, a contract; if for others, the responsibility of whom I knew well, I would consider a telegram or letter engaging me to be sufficient.

3. Generally speaking, Yes, if only as a retaining fee, but my relation to, standing with, or knowledge of the persons engaging me would determine this.

4. As a general thing, Yes, and quite properly, I think. Personally, I have made it a rule to supply certain working equipment of my own and to charge a net fee or salary for my services, all else to be for account of the parties engaging me.

5. (a) Reasonable tips to servants, Yes; otherwise, No.

(b) Within reasonable limits, Yes.

(c) No.

(d) Down to occasional 'incidentals,' such as possible cab-fares, baggage-transfers, tips, and like expenses.

(e) Properly, Yes, particularly for amounts exceeding say \$2.

(f) Generally speaking, I would say that such expenses would properly be chargeable to one's own account, though mitigating circumstances might decide otherwise.

(g) Weekly or monthly, with complete statement in detail at end of engagement.

6. I consider it the right of the company to demand, and my duty to supply, periodical reports of the progress of the work in hand. I do not make reports of assays, in detail, or make statements of any kind that would, possibly, conflict with my final opinion and report.

7. No, particularly while still engaged by the company for whom I was acting. Afterward, perhaps, Yes, if such action was not detrimental to my late employers. Should the fact that I have reported favorably on a mine forever preclude my dealing legitimately in its shares? I think not.

8. Always provided that one's employers are not in the field to purchase new ground, and not likely to be for some time to come, and that no company time is lost, I would say Yes, unless my contract with the company stipulated otherwise. I would, however, in such an event, advise the company of my action and freely offer to turn over such ground to it if it so desired. Mining is hardly a competitive business.

9. None whatever, on lines stated in the question.

10. (a) For my part, I do not think that one is at all times justified in saying 'Yes' or 'No.' No one can say with all certainty just what development will demonstrate for a mining property. I have seen mines which, on the surface, or in their early stages, were anything but promising properties, and yet which developed into successful mines. On the contrary, I have seen, on the surface, 15 ft. of pay-ore that, within 20 ft. of the outcrop, all but disappeared and never came in, in quantity, again. This is a broad question and must be answered in a broad way. I do not believe that any engineer is justified in saying either 'Yes' or 'No' concerning any property, unless he has sufficient information at hand on which to base an intelligent opinion; prejudice for or against a certain district, brought about by any one or all of a dozen different conditions, or against, perhaps, a certain formation, should not enter into calculations unless all the governing facts are at hand. I have in mind one engineer who, sent to pass on a whole district in a country strange to him, let the personal discomforts to which he was subjected on the trip influence his whole report, to the discredit of the district in question. Again, I know of another engineer, employed by a copper company in the early stages of its development operations, who thought that every dollar spent in the work had been wasted because, strange in his opinion, the ore was found within the confines of a certain formation. Had this man made the first report on the property he would have said 'No,' and yet the mine in question has developed into a very successful proposition. I do not advocate 'hedging,' but neither do I advocate a 'Yes' or a 'No' unless the facts so warrant.

(b) I would say that an engineer would not be justified in attempting the work outlined, to any considerable extent, unless under proper authority from his employers.

The assumption is that a mine about to be investigated is prepared and made ready for examination. When such is not the case, or where the mine is an old one, badly caved and bottoms under water, such work, if performed, should not be charged to one's expense account, by which is meant charges for traveling, living, and other, generally minor, expenses, but as one of the major costs of the examination.

NORVAL J. E. WELSH.

San Antonio, Texas, October 16.

The Editor :

Sir—I have just received your letter with enclosure of 'Searching Questions,' with a request from you that I

answer them. I have carefully read the prelude and questions following. They forcibly suggest to me the necessity of establishing in our technical schools a new chair to teach their students how to avoid graft.

1. It is a good plan to charge a fee to cover all expenses for professional work.

2. It depends upon who your employers are; generally I should say a letter or telegram was sufficient between reputable people.

3. Yes, and I think it a good plan.

4. This question is a bit ambiguous. The employer can only be properly charged with labor and materials actually used in an examination.

5. (a) These expenses are none of them legitimate unless specially agreed to in advance by employer.

(b) In answer to this question I should say that an examining engineer is entitled to first-class accommodations by land and sea.

(c) This savors too much of petty larceny.

(d) Expense accounts should be kept in great detail, no charges made to an employer that cannot be itemized. 'Incidentals' are not permissible.

(e) It is a good plan to take vouchers for expenditures where possible.

(f) Such expenses should certainly not be charged to an employer.

(g) This is a matter for the employer to decide.

6. Preliminary or periodical reports are to be avoided where possible.

7. In answer to the first part of this question, regarding purchase of shares by an examining engineer during the examination, certainly no reputable engineer would resort to such methods. After a report has gone to the directors and shareholders, I should think it permissible. It is, however, a very poor plan for an examining engineer, who desires to make a reputation for himself, to try and make money by speculation in mining shares.

8. In answer to this question I would say it is always easy to communicate with your employer on such subjects before acting on your own account.

9. I cannot see why an employer would object to your publishing your views concerning any district.

10. It is certainly not expected of an engineer to say 'Yes' or 'No' to anything he is in doubt about. He is supposed to represent to the employer just what he sees. Regarding the earlier part of this question, it is often necessary to unwater mines and clear out old drifts, and in such cases it is nearly always possible to communicate with your employer by letter or telegraph. It is always well to learn as much about a property as possible before starting the examination.

RALPH NICHOLS.

Gabriel, Durango, Mexico, October 22.

Questions by a Practical Miner.

The Editor :

Sir—A few days ago on one of my trips through the mountains, I met a miner who had been at work at the old mine Y at Z. Of course, we stopped for a chat, as he always has some questions to the point. This Y mine has some old equipment, but at present there is being installed a large steam plant to generate electricity at a central point and distribute to motors operating the stamp-mill, compressors, hoists, and lights; which is all right, so far as a central power-plant goes. But one day when the superintendent came by, the practical miner asked why they had not put in a hydro-electric plant, as there was plenty of water and head to be obtained within two or three miles of the mine, for power the year round.

The superintendent did not know, as the general manager had bought the plant, et cetera. Also the practical miner wanted to know why the steam plant had three large boilers of some 200-hp. capacity each, two good feed-pumps, also injectors, then one large Corliss engine of some 600-hp. belt-driven generator instead of three engines of 200 hp. each, direct connected to generators. Why should they put all their eggs in one basket? What will you do if your big engine goes lame, or generator burns out? he asked. With your plant in triplicate you could perhaps have ore enough in the stopes and bins so that you could stop the compressors and keep the mill going. Now, if the single plant stops, the whole work stops. Again, the mine is about 35 miles from a railway point. Boilers weigh about nine tons each, the fly-wheel is in two parts, with a total weight of about 16 tons. The engine must weigh as much as a boiler. The first boiler, when hauled in, took 12 horses, three or four men, and three weeks to make the trip. There is plenty of good timber around. The power plant is in a part of California where the average rainfall must be about 60 inches. The lack of sheds to cover the wood will cause some hustling to keep up steam.

Another day the practical miner was helping on some concrete foundations at a new mill. He asked the superintendent if he could not have two helpers on the quartz cropping just above the mill to get out quartz for concrete instead of two men who were down on the river screening and sacking gravel. This was being sacked and hauled up a very steep hill by a four-horse team, one driver and swamper in small loads. The superintendent replied that it was all right as it was. The practical miner said all kinds of tools were short; he had lost enough time each week hunting for a pick or shovel to have paid for a new one. A few days later the practical miner received his time, although the company was needing men badly. The practical miner supposed he had asked too many questions.

W. E. T.

Auburn, September 29.

[This is well enough, but the emphasis is in the wrong place. The man who pointed to the mistakes made by the manager was not necessarily a 'practical miner,' he was just a plain man of common sense. In the first place it was not a question of mining; an intelligent mechanic, blacksmith, or assayer could have detected the blunders mentioned. Most 'practical' miners would have failed to do so.—Editor.]

Slime Treatment.

The Editor:

Sir—As a contributor to your valuable paper for some years past, I frequently see letters which, were I closer to hand, would tempt me to put in my oar. In your issue of April 20 just received I notice a letter signed by Edward H. Nutter, which would give the credit of successful slime treatment, and more particularly the idea of cleaning the filters with compressed air to George Moore. Now I claim the originality of this (and I think justly so) to myself. And so that your contributors may judge for themselves, I refer you to attached specification of U. S. Patent No. 619,211 taken out by me in February, 1899. There is an old saying "a prophet is not a prophet in his own land," and such has been my experience. My effort to get the process here described in practical use only succeeded in advertising to others the value of my ideas, and the most that I was able to do was to get a partner in with me who for five years tied my hands; he would not go forward, nor would he go out of it, until about 18 months ago, when I succeeded in inducing him to retire. In the meantime

Moore and several others had got established, and my right (assuming I have rights) would mean litigation. My experience to the present is a loss of over £1,000, experimenting and patenting, the latter alone with renewal fees absorbing £800 or thereabout. This, so far, is my share for solving for the world at large one of the most difficult problems in the metallurgy of gold. For the benefit of inventors generally, I would emphasize the importance of employing a conscientious and capable man to draw up his specifications and would add my opinion is that some patent agents are not interested in pro-

fecting fully the rights of a 'master' patent, I presume for the reason it interferes with business from their point of view.

ASKNI M. NICHOLAS.

Talmalmo, New South Wales, July 5.

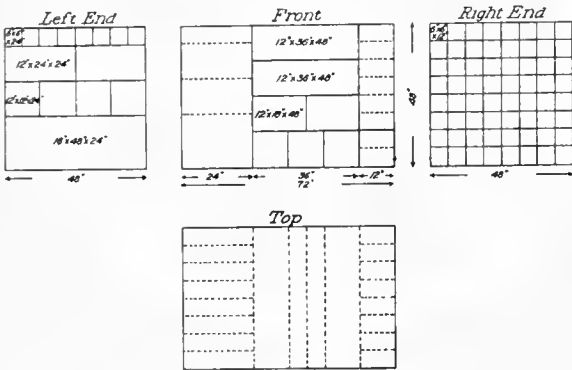

ASBESTOS IN CALIFORNIA.—One of the direct consequences of the earthquake and fire of San Francisco is a greatly increased demand for asbestos on the Pacific coast. Prospecting for asbestos has been stimulated. The large masses of serpentine in the Klamath Mtn. and in portions of the Sierra Nevada, afford promising fields. Several new finds have been reported from California, near the western border of the great belt of serpentine which extends from Plumas county south through Sierra, Nevada, Placer, Amador, and Calaveras counties.

System of Map-Filing.

Written for the MINING AND SCIENTIFIC PRESS
By G. N. PFEIFFER.

A description of the system I have installed at the Santa Franciscan mine may be of interest to some of your readers. Before this was done no one knew just what maps were here, and if he did know a certain map was here the chances were he would have to look for several hours to find it. After examining most of the drawings I devised this method for both the maps now on hand and those to be collected in the future.

The first consideration was a cabinet. The maps are from 6 to 48 in. wide, and from 6 in. to 12 ft. or more in length, so the pigeon-hole had to be used, still as a narrow plat might come under the same heading as a wide plat it would not do to place all in a box long enough for the wide plat. A cabinet as shown in the accompanying sketch was decided on. This really makes three cabinets. The right end has a depth of one foot; the left end two feet; while the centre or front has a depth equal to the width of the end compartments, four feet. The right end is known as A, the centre as B, and the left as C.

A Cabinet for Maps.

Below each box is pasted a small label to show what numbers belong to that box. The dimensions given on the drawing do not allow for thickness of partitions.

The catalogue is divided as follows:

		No. of Map.	Page.
Mining	Surface..	Denounce- { Company's.. 0-100	22-26
		ments .. { Others	27-40
		Topographical	41-42
		General	43-46
	Underground..	Plans	47-58
		Elevations	59-62
		Miscellaneous	63-68
	Timber	901-950	69-71
	Miscellaneous	951-1000	72-75
	Engines and boilers.....	1001-1100	76-80
Mechanical ...	Pumps	1101-1200	81-83
	Foundations.....	1201-1240	86-87
	Cars	1241-1270	88-89
	Cages	1271-1300	90-91
	Miscellaneous	1301-1500	92-101
Railroad.....	Cross-sections	1501-1550	102-103
	Plans of route	1551-1600	104-106
	Topographical	1601-1625	107
	Switches and frogs	1626-1650	108-109
	Trestles	1651-1675	110
	Miscellaneous	1676-1800	111-116
General	Real estate and leases.....	1801-1850	117-118
	Buildings	1851-1950	119-124
	Electric installation.....	1951-1975	125-126
	Ore-bins	1976-2000	127
	All others	2001-2200	128-137

The numbers of the second column under the heading 'Page,' refer to pages of the catalogue, where a description is given of each plat that comes under that particular division. The numbers in the other column refer to the numbers given to the plats; these are printed in red in the lower right-hand corner on the back; the number on each plat is the same as given with the description in the catalogue. Take for example an 18 by 20 in. blue-print of a one-horse whim. On the back in the lower right-hand corner of the blue-print is the number 2001C (in red), the C shows that this will belong in the left end compartment. In the catalogue on page 128 make this

entry, "2001C (in red). One-Horse Whim; print; 6-3-07." Next cross-index under 'Timbering' and 'Hoists' or 'Engines,' but then give the number 2001C in black. If the description is long, space can be saved when cross-indexing by only giving a key-word and the page where the full description is made. For the catalogue an ordinary surveyor's field-book was used. Most of the maps are rolled and held by a rubber band, the other few are folded. Those that are folded all have the numbers in the same relative position.

The upper part of B is handy for unfinished plats. The lower part of C is for the surveying instruments. The cabinet sets six inches above the floor. It was put together by screws; it is too large for the office-door. Another nice thing is the false top, which can be lifted and used as an extra drawing-board.

COBALT ORE.—The development of Cobalt camp as a silver district has been rapid. In 1905 and 1906 a tremendous amount of prospecting and development work was done, and the value of the ore shipped placed Cobalt in its position as one of the world's rich silver districts. In 1904 there were four shipping mines, the output being 150 tons of ore, valued at \$136,218. In 1905 there were additional mines which shipped ore, the total output amounting to 2,144 tons, valued at \$1,468,524. In 1906 many other properties sent out ore, the shipments totaling 5,129 tons, valued at \$3,900,000. These figures include the cobalt, nickel, and arsenic in the ore, for which in many instances little or nothing was paid to the shipper. In considering the above figures it must be noted that they represent only the ore shipped. The actual production of the camp was greater, as large quantities of ore were stored on several properties. Most of the ore is shipped to smelters near New York. Ore which in any other camp would be considered as high-grade is thrown on the dump at Cobalt on account of the high freight rates to the smelters, making it unprofitable to ship. Thousands of tons of low-grade ore now on the dumps could be shipped a short distance at a profit to the owners. The record of the first six months of 1907 shows shipments of 6,431 tons of ore, valued at \$4,900,000, as against 5,150 tons for the whole of 1906, valued at \$3,900,000.

AFGHANISTAN MINING.—Afghanistan may some day be a great mining district. It is known to have mines of rubies, topaz, lapis lazuli, marble, and other stones; iron, lead, copper, antimony, and other metallic ores; sulphur and several of the earthy alkaline and metallic salts. Coal is also found, and is believed to be extensive near the iron mines. The lead, iron, and precious stones mines are partially worked by the Government with modern machinery, but the mining of the country is mostly carried on by crude processes, and the bulk of the mineral wealth is as yet not touched. According to the few European geologists who have had access to the country, the mineral deposits of various kinds are rich and extensive, and there are to be found both gold and silver in paying quantities. In addition to coal, iron, and other mines, Afghanistan has numerous waterfalls available for power. If the Government would grant railroad and mining concessions to foreigners, the country would develop rapidly, for its mines alone would attract many prospectors, and if found to be as extensive as currently believed, much capital would follow. The Government and people, however, are united in opposing any concessions to foreigners, or even to allowing a white man to take up residence there, as they believe it would eventually result in the white men dominating and controlling the country.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE work done by a lessee can be applied to the assessment work due on a claim, and if it is sufficient in amount, that is \$100, no more work need be done for that year.

THE first electric mine locomotive, used in the United States, was built in 1887 and used that year in the Lykens Valley coal mine belonging to the Pennsylvania Railroad. A later one built in 1889 is still in actual service. These were of high clumsy construction little resembling the low, compact, rugged design now prevalent in mine locomotives.

THE main progress in petrography in recent years has resulted from using reflected light in examining opaque substances. Metallographists depend entirely upon reflected light in their research with the microscope. The polishing of ores and the subsequent etching of them with acid prior to examination by reflected light under the microscope has made it possible for petrographers to learn much about the paragenesis of the ore-forming sulphides.

THE occurrence of an area of schist in the Gunnison district is an interesting feature, for, although there are other stretches of these rocks, represented by the actinolite schist of the Arkansas valley and the hornblende schist of the western slope of the Sangre de Cristo, this particular rock is unusual in the mining regions of Colorado, and is not there considered a rock favorable for precious-metal veins, a fact in striking contrast to California, South Dakota, Rhodesia, and other productive regions.

It is often desirable to sample streaks of ore known to be in the foot-wall or the hanging wall of a stope. This can be done by means of drill-holes put into the hanging wall or the foot-wall. The dust is saved and carefully sampled; the depth of the hole drilled and the width of vein represented by the sample are also noted. From these the value of the ore can be easily calculated. This is a cheap way of finding out whether the streak is worth developing; especially is this to be recommended in the case of ore-filled stopes, where the disposal of the waste rock coming from cross-cuts would be difficult.

THE deepest mine in Rhodesia is being worked at a depth of between 1,300 and 1,400 ft. The gold mines of Rhodesia greatly resemble those of California. The Rhodesian veins occur in belts of schists quite similar to the slate belts of California. The veins are narrow being from 3 to 8 ft. in width, generally speaking, and the value of the ore is between \$1 and \$20. Four-dollar ore can be worked at a profit in Rhodesia. The Kafirs are paid about \$15 a month and their food. One white miner is put in charge of 15 to 20 'boys.' Machine drilling is used in mining the wide stopes while hand-drilling is used in the narrow stopes.

THE limit of productiveness in the Smuggler vein at Telluride, Colorado, coincides to a remarkable degree with the base of the rhyolite, where the vein is pinched becoming a mere parting. In the rhyolite the vein is accompanied by a little selvage and some scattered patches of silver ore but nowhere has any cellular quartz, such as is common lower in the vein, been found. In the underlying augite-andesite the bonanza orebodies occur; the richer masses of silver ore are found to follow roughly the harder, almost horizontal, layers of andesite.

Similarly in the underlying breccia, which is fine-grained, the pinches in the vein occur along nearly level lines coinciding with the bedding-planes of the country.

THE loss of power in compressed air transmission at mines is great on account of leakage, and also because of the high friction loss due to the crookedness of the piping. These losses are generally far greater than in the case of electricity, which is especially adapted to transmission through crooked drifts, etc. The one advantage attending the use of compressed air for power is that it aids in ventilating the mine. It is often worth a good deal to a company to be able to open a valve and blow the smoke out of some poorly ventilated stope; by decreasing the length of time that miners are kept idle by this smoke, it often saves considerable money to the company.

MANY difficulties were encountered when electric power transmission was first introduced underground. The air in mines is damp and this moisture condenses on the wires, the insulators, and on the walls of the drifts. All these facts make it easy for much power to leak away. To avoid this leakage insulators have been specially designed which practically prevent leakage of current. Owing to the limited amount of head-room the insulators, hangers, etc., have to be designed to economize this head-room as much as possible. Owing to the moisture condensing on the wires and its reaction with the oxidizing particles of ore and dust which settle on the moist wires, and also on account of warm gases from hot stopes, insulation deteriorates rapidly underground. For that reason a person should consider that all insulated wires underground, which are not armored, are live wires, and act accordingly.

THREE or four years ago when anvil-blocks were introduced into stamp-battery construction they were considered to be a great improvement. They were introduced to help make the mortar-box more solid and also, by distributing the stress on the mortar-block over a larger area, to help lengthen its life. Experiments at the Alaska Treadwell mill in Alaska and at the Geldenhuis Deep in South Africa indicated an increase of about 15% in the crushing capacity due to the introduction of anvil-blocks. It is rather disconcerting therefore to learn that the new 300-stamp mill of the Simmers Deep—the only new mill building on the Rand—will not have anvil-blocks although the stamps are over 150 lb. heavier than any other stamp-heads on the Rand. The mortar-box will rest upon a small rubber cushion placed on the concrete mortar-block. The mill will be run by electricity.

ELECTRIC blasting has many points in its favor. In the first place there is practically no danger of hang-fire (although a few isolated cases have been reported from English coal mines) when electric blasting is used; all holes are fired simultaneously so that the compression waves from one explosion meet those of another, thus reinforcing each other, making the explosion more effective. As there is no fuse to burn, only the gases from the exploding dynamite vitiate the air. As most of the smoke from blasting is caused from the burning fuse and as it is by the amount of smoke in a stope after blasting that miners determine when they will return to work, this last item of less smoke is not to be despised. But electric firing has this one great drawback, the force of the concussion and the shock of the explosion are so great that it can not be used in timbered stopes. Besides it does not pay to fire with electricity if only a few holes are fired at a time. In stopes where there is no timbering and a large number of holes are fired, electric blasting is to be recommended.

A Broad Apex.

One of the vexing questions of the United States mining law relates to the rights of claim-owners in the case of a lode so wide that the whole of its apex is not included within the side lines of a single property. Here-with we print, in its entirety, the decision of the Supreme Court of the United States in the case arising out of litigation at Bingham, in Utah. The decision is dated October 21, 1907, and further comment will be found on the editorial page of this issue.

This suit was commenced in the Circuit Court of the United States for the District of Utah by the United States Mining Company, claiming to be the owner of certain mining property, and praying that its title thereto be quieted and the defendant restrained from taking any ore therefrom. Jurisdiction was founded on diverse citizenship. In an amended complaint, filed June 2, 1902, it was alleged that the plaintiff is the owner and in possession of four mining claims known as the Jordan Extension, the Northern Light, the Grizzly, and the Fairview lode mining claims, the boundaries of each being given; that these mining claims are adjacent to each other and to certain other mining claims, all owned and worked by the plaintiff as one property for mining purposes: that beneath the surface of the claims above mentioned is a vein or lode of great value; that the defendants wrongfully claim to own said vein or lode and the ores and minerals therein contained; that they have by means of secret underground works obtained access thereto, and have mined, extracted and removed large quantities of valuable ores therefrom; that they threaten to continue such wrongful and unlawful invasion of the premises, and to continue to mine, extract and remove ores and minerals; that the defendants are in possession of a mining claim adjacent to the four mining claims of plaintiff, known as the Kempton mining claim, United States Lot 255, which was located in the year 1871, and on information and belief that the defendants pretend that the mineral deposits and ores under and beneath the surface of the four mining claims above mentioned are in and part of a mineral vein and lode belonging to and having its apex in said Kempton mining claim and on the dip of said alleged vein, which pretence the plaintiff charges to be contrary to the truth. The plaintiff further alleges that it is the owner and in possession of two certain mining claims, one named the Jordan Silver Mining Company's mine, but usually known as the Old Jordan, located December 17, 1863; the other the Mountain Gem Lode and Mining Claim, located August 20, 1864, the boundaries of each of which are given; that in these two claims there is a lode, bearing silver and other metals, whose apex is within the surface; that the dip of said lodes is toward the Kempton claim occupied by the defendants, and that if there be any mineral vein or lode in the Kempton claim it is not one that has its apex within the limits of that claim, but is a part of the lode apexing within the Old Jordan and Mountain Gem claims. The relief prayed for was a decree quieting plaintiff's title and restraining the defendants from mining and removing any ores or minerals. To this amended complaint the defendants filed a demurrer, stating, as one of the grounds thereof, that the plaintiff had an adequate remedy at law. This demurrer was overruled, and thereupon the defendants filed an answer and subsequently an amended answer, setting forth their title to the Kempton mining claim, and also to a claim known as the Ashland mining claim, and alleging that there are lodes whose apices are within these claims; that on their dip they enter beneath the surface of the plaintiff's claims, and that it is upon them

that defendants have been mining; that the Kempton claim was patented to their grantors and predecessors in interest on February 23, 1875. They further deny that the Old Jordan claim was located on December 17, 1863, or patented July 14, 1877; deny that the Mountain Gem claim was located on August 20, 1864, or that a patent had been issued on said alleged location. They further aver that if there be any lode or vein in either the Old Jordan or the Mountain Gem claims, that such lode or vein is entirely distinct from those which have their apices in the Kempton and Ashland claims. On the hearing the court denied the application of the defendants to set the case for trial as a law case before a jury. At the same time it entered a decree dismissing the plaintiff's bill. From this decree the plaintiff appealed to the Circuit Court of Appeals (67 U. S. App. 587), which reversed the decree of dismissal, and remanded the case with instructions to enter a decree for the plaintiff in conformity with the prayer of the bill. Thereupon, on application of the defendants, the case was brought to this court on certiorari.

Mr. Justice Brewer delivered the opinion of the Court.

The first question is, whether the plaintiff can maintain this suit in equity without a prior adjudication in an action at law of its legal title. The bill alleges ownership and possession. It supported this allegation by patents from the United States of the first four claims mentioned in the bill, and proved that the defendants were working on a vein or body of mineral beneath the surface and extracting ores therefrom. The bill has a double aspect, to quiet title and to restrain defendants from removing any more ores from beneath the surface of these claims. Title by patent from the United States to a tract of ground, theretofore public, *prima facie* carries ownership of all beneath the surface, and possession under such patent of the surface is presumptively possession of all beneath the surface. This is the general law of real estate. True, in respect to mining property, this presumption of title to mineral beneath the surface may be overthrown by proof that such mineral is a part of a vein apexing in a claim belonging to some other party. But this is a matter of defense, and while proof of ownership of the apex may be proof of the ownership of the vein descending on its dip below the surface of property belonging to another, yet such ownership of the apex must first be established before any extralateral title to the vein can be recognized. This suit was not in the nature of an ejectment, to put the defendants out of possession of the space beneath the surface of plaintiff's claims from which they had extracted ore, but to quiet the title of the plaintiff to the vein in which they had been working, and to restrain them from mining and removing any more ore.

Sec. 3511, Rev. Stat., Utah, 1898, reads:

"SEC. 3511. An action may be brought by any person against another who claims an estate or interest in any real property adverse to him, for the purpose of determining such adverse claim."

A statute of a similar character was before this court in *Holland v. Challen*, 110 U. S. 15, and it was held that under it a suit might be maintained by one out of possession against another also out of possession to quiet the title of the former to the premises. It was said, quoting from a prior opinion, that it was "a case in which an enlargement of equitable rights is effected, although presented in the form of a remedial proceeding." It was also said (p. 20):

"To maintain a suit of this character it was generally necessary that the plaintiff should be in possession of the property, and, except where the defendants were numerous, that his title should have been established at law or

be founded on undisputed evidence or long continued possession. *Alexander v. Pendleton*, 8 Cranch, 462; *Peirsoll v. Elliott*, 6 Pet. 95; *Orton v. Smith*, 18 How. 263.

"The statute of Nebraska authorizes a suit in either of these classes of cases without reference to any previous judicial determination of the validity of the plaintiff's right, and without reference to his possession. Any person claiming title to real estate, whether in or out of possession, may maintain the suit against one who claims an adverse estate or interest in it, for the purpose of determining such estate and quieting the title."

The same question was considered and decided in the same way in respect to a suit, based upon a similar statute, in Iowa, in *Wehrman v. Conklin*, 155 U. S. 314. Of course, as pointed out in *Whitehead v. Shattuck*, 138 U. S. 146, such a statute cannot be relied upon in the Federal courts to sustain a bill in equity by one out of possession against one in possession for an action at law in the nature of an action of ejectment affords a perfectly adequate legal remedy. There is nothing in the point decided in *Boston etc. Mining Company v. Montana Ore Company*, 188 U. S. 632, which, rightly considered, conflicts with the case of *Holland v. Challen*.

It will be further borne in mind that this question was raised by demurrer to the plaintiff's bill and by motion

nature of an action of ejectment, which was a common law action, entitling the party to a jury. But in this case upon the allegations of the complaint the plaintiff was in possession and therefore could not maintain an action of ejectment. The testimony which plaintiff offered showed that it was the owner and in possession, and, of course, at that time nothing in the nature of an action of ejectment was shown. And it was only by demurrer to the complaint and by motion after the plaintiff had rested that the question of a right to a jury was raised by the defendants. The decision of the Court of Appeals in this matter was right.

Coming now to the merits, it is not open to dispute that the defendants were taking ore from beneath the surface of the plaintiff's four claims. The question, therefore, arises what right had they to thus mine and remove ore? They must show that the ore was taken from a vein belonging to them. Was there a vein? Where was its apex, and who was the owner of that apex? The testimony is voluminous, and even with the accompanying diagram it is difficult to come to a satisfactory conclusion as to the facts.

It is insisted that the findings of the Circuit Court should have bound and concluded the Court of Appeals upon questions of fact. The difficulty with this contention is that there is nothing to show what the Circuit

Court found to be the facts. Whatever might have been suggested by the course of the argument at the hearing, the comments of the court upon such argument, or in announcing its decision, there is nothing in the record to indicate whether its decision was based upon a question of fact or a matter of law. The record only contains its decree, dismissing the bill. All else is a matter of surmise, except as may be inferred from the allegations of the pleadings and the scope of the testimony. While it is apparent that the Circuit Court must have based its decision upon one of two or three grounds, yet upon which it is not certain. The Circuit Court of Appeals made no separate finding of facts, but it filed an opinion which indicates the scope of its decision, and it is the decree of that court which is before us for consideration.

The attitude of the case is very like that of one in which a trial court refers all things to a master who takes the testimony and reports it, with a general finding for the plaintiff or defendant, upon which report the trial court states its views of the facts and the law and enters its decree. An appellate court reviewing such decree will give its consideration to the conclusions stated by the trial court, irrespective of the report of the master, unless the issue be so narrow that sustaining the decree of the court necessarily involves an overruling of the master on a matter of fact.

From the opinion of the Court of Appeals it appears that it found that there was a broad vein. It says: "A careful examination and consideration of the evidence clearly convinces us that the stratum of limestone constitutes a single broad vein or lode of mineral bearing rock extending from the quartzite on one side to the quartzite on the other." This stratum of limestone underlies the four claims of the plaintiff, and one of the contentions of the defendants is that there are several independent veins, one of which has its apex within the surface lines of the Kempton and another its apex in the Ashland, that these independent veins continue down through the stratum of limestone beneath the surface of the plaintiff's claims, and that it was only from these independent veins that the defendants were mining and removing ore. Of

Diagram Showing Conflicting Claims.

after the plaintiff had finished his testimony and before the defendants had introduced theirs, and was not renewed at the close of the trial, although until then the motion was not decided. At the time the motion was made the case presented was one of a clear legal title to the four mining claims by patent from the United States, and an unauthorized entry by subterranean workings into the ground below the surface and the mining and extracting of ores therefrom—a case for restraint by injunction, which was part of the relief asked for in the bill. It is insisted that in *Park v. Wilkinson*, 21 Utah, 279, the Supreme Court of that State has given a different construction to the statute, but in this we think counsel are mistaken. In that case the plaintiff brought an action which the court says "was in the nature of one in ejectment." To the complaint the defendant, as authorized by the practice in Utah, answered with a cross complaint demanding equitable relief. A jury was empaneled. After the testimony was all in, the court ruled against the claim for equitable relief, discharged the jury and entered judgment for the plaintiff. This was held to be erroneous, the court saying that "after determining the equitable issue the court should have submitted the case to the jury upon proper instructions." In other words, the equitable relief sought by the defendant having been denied the case stood as one in the

course, this difference between the conclusions of the court and the contentions of the defendants affects materially the scope of the inquiry. If the limestone is not, strictly speaking, a vein, but a mere stratum of rock through which runs several independent veins, then the inquiry must extend to the location of the apex of each separate vein, whereas if the stratum of limestone is itself a single broad vein, then the inquiry is narrowed to the location of its apex.

With reference to the conclusion of the Court of Appeals it is sufficient to say that if the testimony does not show that it is correct, it fails to show that it is wrong, and under those circumstances we are not justified in disturbing that conclusion. It is our duty to accept a finding of fact, unless clearly and manifestly wrong.

Treating this limestone as a single broad vein, it is apparent that the entire apex is not within the surface of either the Kempton and Ashland, but that it is also found in the Old Jordan and Mountain Gem, the property of the plaintiff. The line which divides the surface of the claims of the defendants from the Old Jordan and Mountain Gem claims also bisects the vein as it comes to the surface. In other words, part of the apex is within plaintiff's claims and part within defendants'. In such a case the senior location takes the entire width of the vein on its dip. This was the conclusion of the Court of Appeals, as shown by this quotation from its opinion (p. 592):

"Where two or more mining claims longitudinally bisect or divide the apex of a vein, the senior claim takes the entire width of the vein on its dip, if it is in other respects so located as to give a right to pursue the vein downward outside of the side lines. This is so because it has been the custom among miners, since before the enactment of the mining laws, to regard and treat the vein as a unit and indivisible, in point of width, as respects the right to pursue it extralaterally beneath the surface; because usually the width of the vein is so irregular, and its strike and dip depart so far from right lines, that it is altogether impracticable, if not impossible, to continue the longitudinal bisection of the apex throughout the vein on its dip or downward course; and because it conforms to the principle pervading the mining laws, that priority of discovery and of location gives the better right, as is illustrated in the provision giving to the senior claim all ore contained in the space of intersection where two or more veins intersect or cross each other, and in the further provision giving to the senior claim the entire vein at and below the point of union, where two or more veins with distinct apices and embraced in separate claims unite in their course downward. Rev. Stat. Sec. 2336."

We fully endorse the views thus expressed. Discovery is the all-important fact upon which title to mines depends. Lindley, in his work on Mines, 2d ed. Vol. 1, Sec. 335, says:

"Discovery in all ages and all countries has been regarded as conferring rights or claims to reward. Gamboa, who represented the general thought of his age on this subject, was of the opinion that the discoverer of mines was even more worthy of reward than the inventor of a useful art. Hence, in the mining laws of all civilized countries the great consideration for granting mines to individuals is *discovery*. 'Rewards so bestowed,' says Gamboa, 'besides being a proper return for the labor and anxiety of the discoverers, have the further effect of stimulating others to search for veins and mines, on which the general prosperity of the State depends.'"

The two thoughts here presented are reward for the time and labor spent in making the discovery, thus adding to the general wealth, and incentive to others to

prosecute searches for veins and mines. To take from the discoverer a portion of that which he has discovered and give it to one who may have been led to make an adjoining location by a knowledge of the discovery and without any previous searching for mineral is manifest injustice.

Again, as indicated in the quotation from the Court of Appeals, continuing the line of division shown upon the surface through the descending vein would be attended with great difficulty and uncertainty. Dealing with questions of this nature, a practical view must be taken. Veins do not continue of uniform width in their descent, but are often irregular and broken, and to attempt to make a division of ore according as it appears on the surface, or equally, would require the constant supervision of a court. It is not strange, then, that the custom of miners has been, as stated by the Court of Appeals, to regard and treat the vein as a unit and indivisible in point of width and belonging to the discoverer. This question has been before this court, as well as several of the courts in the mining districts. In *Argentine Company v. Terrible Company*, 122 U. S. 478, 484, we said:

"Assuming that on the same vein there were surface outcroppings within the boundaries of both claims, the one first located necessarily carried the right to work the vein."

In *Mining Co. v. Mining Co.*, 5 Utah, 3, the question is discussed at some length by Chief Justice Zane. In the course of the opinion it is said (p. 54):

"Under the law of 1866 the surface ground was merely for the convenient working of the lode. The discoverer and first locator took the lode in its entirety. The law contemplated its segregation in its length, not in its width. It refers to lodes between the end lines, not to a part of a lode. No expression can be found in it indicating an intention to limit the rights of the locator to a portion of the lode in its width. The discovery of any part of the apex of a vein is regarded by it as a discovery of the entire apex. And we think that the law of 1872, when all of its provisions are considered together, and in connection with the former law on the subject, as it should be, evinces the same intent. Under this law the discoverer of any part of the apex gets the right to its entire width, despite the fact that a portion of the width may be outside of the surface side lines of his claim extended downwards vertically. While he has no right to the extralateral surface he has a right to the extralateral lode beneath the surface."

Company*, Circuit Court of Appeals (9th Cir.), 52 C. C. A. 219. Also another suit between the same parties in the same court, 66 C. C. A. 99; *Last Chance M. Company v. Bunker Hill S. M. & C. Company*, Circuit Court of Appeals (9th Cir.), 66 C. C. A. 299.

But it is contended by the defendants that both the entries and patents of the Ashland and Kempton claims were prior in time to the entries and patents of the Old Jordan and Mountain Gem, and that such priority of entry and patent conclusively establishes the prior right of the owners to this broad vein; that the failure of the owners of the Old Jordan and Mountain Gem to adverse the applications of the owners of the Ashland and Kempton for patent was an admission that the latter had priority of right, and is conclusive against any present testimony as to the dates of the locations. We had occasion in the recent case of *Mining Company v. Tunnel Company*, 196 U. S. 337, to consider to what extent the issue of a mining patent worked an estoppel of the claims

of third parties, and it is unnecessary now to repeat the discussion there had.

This case presents the question under different aspects. The entries and patents of the Ashland and Kempton claims were, as stated, prior in time to the entries and patents of the Old Jordan and Mountain Gem. There is no record of any adverse suits, although it is intimated that there were such suits. In the absence of a record thereof we cannot assume that anything more was presented and decided than was necessary to justify the patents. A patent is issued for the land described and all that is necessarily determined in an adverse suit is the priority of right to the land. This is evident from the section, 2325 R. S., which says: "A patent for any land claimed and located for valuable deposit may be obtained in the following manner." In the section the only matters mentioned for examination and consideration relate to the surface of the ground. There is no suggestion or provision for any inquiry or determination of subterranean rights. Lindley, in his work on Mines, second edition, Vol. 2, Sec. 730, says:

"An application for patent invites only such contests as affect the surface area. A possible union of veins underneath the surface cannot be foreshadowed at the time the application is made. When such a condition arises, it is adjusted by reference to surface apex ownership and priority of location not involving any surface conflict. The rule is well settled that conflicting adverse rights set up to defeat an application for patent cannot be recognized in the absence of an alleged surface conflict. Prospective underground conflicts are not the subject of adverse claims."

In *New York Hill Company v. Rocky Bar Company*, 6 L. D. 318, the Commissioner of the General Land Office declined to recognize an adverse claim where there was no surface conflict, saying (p. 320):

"In the event that patent should be issued upon said application and any question should thereafter arise as to the right under such patent to follow any vein or lode, as indicated in sec. 2322, it would be a matter for the courts to settle, and I am of the opinion, there being no surface conflict alleged in this case, and without considering any other question relating to the sufficiency of the so-called adverse claim, that you properly declined to receive the same as an adverse claim, and to that extent your decision is affirmed."

The same ruling was made in *Smuggler Mining Company v. Trueworthy Lode Claim*, 19 L. D. 356.

Without determining what would be the effect of a judgment in an adverse suit in respect to subterranean rights, if any were in fact presented and adjudicated, it is enough now to hold that there is no presumption, in the absence of the record, that any such rights were considered and determined. Indeed, in the absence of a record, or some satisfactory evidence, it is to be assumed that the patents were issued without any contest and upon the surveys made under the direction of the United States surveyor general, and included only ground in respect to which there was no conflict. If the surface ground included in an application does not conflict with that of an adjoining claimant, the latter is in no position to question the right of the former to a patent. Take the not infrequent case of two claims adjoining each other, the boundary line between which is undisputed. If the owner of one applies for a patent the owner of the other is clearly under no obligation to adverse the application, even if under any circumstances he might have a right to do so. Other necessary conditions being proved, the applicant is entitled to a patent for the ground. Generally speaking, if the boundary between the two claims is undisputed, the foundation for an adverse suit is lack-

ing. While a patent is evidence of the patentees priority of right to the ground described, it is not evidence that that right was initiated prior to the right of the patentee of adjoining tract to the ground within his claim.

Section 2336, R. S., makes provision for conflict as to certain subterranean rights. The last sentence of the section reads: "And where two or more veins unite the oldest or prior location shall take the vein below the point of union, including all the space of intersection." *Argentine Company v. Terrible Company*, *supra*. As the place of union may be far below the surface, this evidently contemplates inquiry and decision after patent, and then it can only be in the courts. And the same rule will obtain as to other subterranean rights.

It is further contended that there is no evidence of a valid location of the Old Jordan and Mountain Gem prior to the entries of the Ashland and Kempton. Location notices of the Old Jordan and Mountain Gem were admitted in evidence, that of the former being as follows:

"Notice. Jordan S. M. Co.

"The undersigned members of the Jordan Silver Mining Co. claim for mining purposes one share of two hundred feet each and one additional claim of two hundred feet for original discoverer, George R. Ogilvie, on this lead of mineral ore, with all its dips, spurs and angles, beginning at the stake situated one hundred feet northeast of Gardner's shanties in Bingham (Canyon) Canyon, in West Mountain, and running two thousand two hundred feet in a westerly direction along the side of said mountain, on a line with Bingham Canyon, and intend to work the same according to the mining laws of this mining district.

"(Signed by 25 locators.)

"Bingham Canyon, Salt Lake City, Utah Territory Sept. 17, 1863.

"A. GARDNER, Recorder."

The Mountain Gem location was similar in form, dated August 20, 1864, and recorded August 24, 1864. Now these location notices were long before the time of the locations of defendants' claims. It is further contended that the locations of the Old Jordan and Mountain Gem were anterior to the act of July 26, 1866 (14 Stat. 251), which was the first legislation of Congress in respect to the granting of mineral claims, and that while that act in its second section recognizes the rights of locators in so far as they have proceeded according to the local custom or rules of miners of the districts in which the mines are situated, yet in this case there is no evidence that these locations were made in conformity to any such local custom or rules. It is sufficient to say that by stipulation of counsel it was agreed that the patents to the Old Jordan and Mountain Gem were issued upon the location notices. Inasmuch as they were accepted by the Government, and patents issued thereon it was a recognition by the department of the conformity of the proceedings to the local rules and customs of the district, and such ruling is not open to challenge by third parties claiming rights arising subsequently to such notices.

Summing up our conclusions, the findings of fact as stated in the opinion of the Court of Appeals are not clearly against the testimony, and must, therefore, be sustained. According to those findings there was a single broad vein—the apex or outcroppings of which extended through the limits of some of the plaintiff's and defendants' claims—and not several independent veins. The ore which was being mined and removed by the defendants was taken from this single broad vein beneath the surface ground of claims belonging to the plaintiff. Where there is a single broad vein whose apex or outcroppings extend into the adjoining mining claims the discoverer has an extralateral right to the entire vein on

its dip. Acceptance by the Government of location proceedings had before the statute of 1866, and issue of a patent thereon, is evidence that those location proceedings were in accordance with the rules and customs of the local mining district. The priority of right to a single broad vein vested in the discoverer is not determined by the dates of entries or patents of the respective claims, and priority of discovery may be shown by testimony other than the entries and patents. In the absence from the record of an adverse suit there is no presumption that anything was considered or determined except the question of the right to the surface.

From these conclusions it is obvious that the decision of the Circuit Court of Appeals was right; and it is affirmed.

Mineral in Underground Waters.

The chemical characteristics of underground waters depend mainly upon the composition of the rocks with which they have come in contact, varying from point to point according to local conditions. The composition of the waters not only indicates the character of the rocks but determines the use to which particular waters may be put. In fact a knowledge of the significance of the mineral constituents of any water is essential to a proper appreciation of its value and the limitations of its use. The water analyses made in the laboratory of the United States Geological Survey determine the following elements, whose significance and effects are briefly described in the following paragraphs:

Silica, a constituent of a great variety of substances, is present in large amounts in nearly all rocks except limestones and is contained in measurable quantities in nearly all underground waters. The amount ordinarily held in waters is too small to be injurious to health or objectionable in the majority of industrial processes; but the mineral forms a part of boiler scale and on this account it is undesirable in waters used for steam-making.

Iron is a constituent of most rocks and is dissolved to a slight extent by percolating water. Four or five parts per million of this substance render water unpalatable, and two or three parts per million are distinctly recognizable by taste. The iron is generally precipitated on exposure of the water to air, forming a brownish coating on the sides and bottom of the containing vessels and a scum on the surface of the water, but leaving the water itself almost free from iron at the completion of the process. Water containing much iron is very objectionable in laundries, bleacheries, textile factories, and paper mills, because the element distinctly discolors white fabrics and interferes with the coloring of tinted varieties. In the manufacture of fermented beverages iron produces a dark-colored brew that is unattractive in appearance. Iron also causes trouble in water pipes by the development of micro-organisms that secrete this substance and form a reddish slimy deposit that clogs small pipes and frequently is discharged through faucets. Iron forms part of the scale in boilers, though the amount that may be present is small in comparison with that of other incrustants.

Aluminum is a constituent of practically all rocks and forms a large proportion of shales. It unites with lime to form boiler incrustations. It is relatively inert and is harmless to health in the small amounts that are ordinarily present.

Calcium is present in a great variety of rocks. It is one of the chief ingredients of limestones and consequently it predominates in waters draining such deposits. It causes great trouble in boilers, where it forms a deposit that seriously affects their efficiency. If carbonates

predominate in the water, the deposit is a soft bulky sludge that is not troublesome if it is frequently removed by 'blowing off.' If, however, sulphates are present, a hard scale is formed that clings tenaciously to the surfaces on which it is deposited.

Magnesium is commonly associated with calcium in rocks, but generally occurs in smaller amounts. Although its compounds are more soluble than those of calcium it is usually present in ground waters in smaller quantities. It is a more objectionable constituent of boiler waters than calcium. It forms denser and harder scales, especially when precipitated with calcium carbonates, with which it unites in a hydrated incrustation that is as hard as porcelain. Its compounds are also readily decomposed, so that the acid radical attacks the boiler-plates.

Calcium and magnesium are always present in underground waters and are the chief bases in the drainage from limestone regions. They are the so-called 'hardening' constituents, and as such are undesirable in waters employed for general industrial uses, especially in laundries, textile mills, and soap factories, where they form an insoluble soap and thereby greatly increase the consumption of the detergent. In dye works the alkaline earth compounds interfere with the coloring matters.

Sodium and potassium occur in nearly all rocks and are present in greater or less amounts in ground-waters. The compounds of these two elements form no part of the scale in boilers because they are readily soluble in waters, hot or cold. On the other hand, on account of the acid radicals which accompany them, they are the cause of foaming and corrosion. Strong solutions of the carbonates cause foaming, but are not specially corrosive. The sulphates often associated with the alkalies are both foaming and corrosive.

Chlorine has an important corrosive action whatever base may be associated with it. Water containing over 100 parts per million of chlorine is poor for boiler purposes. In water for drinking chlorine is harmless.

The total solids in a water depend largely on the character of the rock it traverses and the intimacy of contact of the percolating waters with it. They are lowest when the waters have just entered the rocks and highest when they have been imprisoned for a long time. They are smallest in porous quartz sandstones and highest in fine-grained shaly rocks, through which waters pass with difficulty. In general it may be said that the smaller the amount of dissolved mineral matter in the water the better it is for steaming and for general industrial purposes.

MICA IN ONTARIO.—It is reported that at Sydenham, Ontario, 16 miles from Kingston, is situated the largest mica mine in the world. The product is mostly amber mica, with some silver amber, the highest quality mined. The mine is one mile from the upper end of Sydenham lake, and the mica is transported in bulk from the mine by barge to the railroad at Sydenham, where it is shipped to Ottawa for trimming for the market. From Ottawa it is exported to the United States and other points. This mine is owned and worked by Americans, and the output is almost entirely taken by American electric companies.

MANGANESE FROM BRITISH INDIA.—Of the exports of manganese ore from Madras, India, during 1906, the United States bought to the value of \$245,000—a little more than half of the value of that ore shipped to the United Kingdom, while Belgium took a little more than half as much as the United States.

Determination of Fluorine.

Written for the MINING AND SCIENTIFIC PRESS
By C. A. HEBERLEIN.

In the presence of carbonic acid, organic substances, and chlorine, the following method may be used by changing the fluorine into SiF_4 , decomposing the same with water, and titrating $\text{SiF}_4 \cdot 2\text{HF}$ with a normal alkali solution. The apparatus to be used is as follows: With a gasometer, air is passed through the wash-bottle *B*, filled one-half with concentrated H_2SO_4 . The cylinders *C* and *D* are half filled with sodium-calcium oxide ($\text{Na}_2\text{O} + \text{CaO}$) in the form of small pieces, and the other half with fused calcium chloride. Bottle *E* of 250-c.c. capacity serves for the decomposition of the fluorine mineral. The rubber cork of bottle *E* has two holes. Through one, the longer tube connects with the air-supply and reaches into the liquid, in which the decomposition is performed, while the shorter tube connects with the bottle *F* filled with concentrated H_2SO_4 , into which reaches a thermometer for reading the temperature. Both bottles stand on an iron plate to be heated by a gas or alcohol lamp. The U-tube *G* is empty and

perfectly dried and connected with U-tube *II*, the front half of which is filled with small pieces of fused calcium chloride, and the back half filled with small pieces of pumice, saturated with dehydrated sulphate of copper, serving to absorb H_2SO_4 and HCl carried over. The dried fluosilicon passes through the dried glass tube *J* into the beaker *K*, the bottom of which is covered with metallic mercury. It is important that this tube touches the mercury to cause constant bubbles and of a small diameter. The pressure in the apparatus must not be too great, as otherwise the bubbles pass off violently and undecomposed fluosilicon may pass over.

To prevent choking of the tube *J* it is necessary to remove from time to time the silica, deposited in the form of a ring, by means of a platinum wire. After the apparatus has been tested as to its tightness, the fluorine mineral is placed with 15 times its own weight of burned quartz powder into the bottle *E* and 40 c.c. of concentrated cold H_2SO_4 is added. Beaker *K* is filled with 150 c.c. water. After the connection is made again, an air current is passed through with one or two bubbles per second. Now the temperature is raised gradually up to 160°C . After the decomposition in bottle *E* is finished, the flame is removed and the bottle *E* is cooled down and for one hour an air current passed through the apparatus. Now cochineal tincture is added and $\text{SiF}_4 \cdot 2\text{HF}$ is titrated to strong alkaline reaction.

What Happens When Advertising Stops.

The following suggestive comment appeared recently in *The Philistine*. It has been reprinted by the Minneapolis Steel & Machinery Co., as a forcible example of the value of advertising. If it were not true it would be uninteresting; because it is undoubtedly true it is worth reading.

Time was when the Mammoth Cave of Kentucky was one of the wonders of the world. The Cave is there yet, but only colored picnic parties go there now, or possibly an occasional person wanders thither because he remembers how, in days ago, his father and mother made their wedding journey here, and then came home and talked of it for the rest of their lives.

Records can be seen at the Mammoth Cave hotel showing the exact number of persons who have visited the Cave since this hotel was opened in 1837. It is worth while to note that in the year 1844 an average of 93 persons per day were shown the wonders of the Mammoth Cave, while in 1905 the average, not counting local picnic parties, was less than a dozen. In 1844 the population of the United States was less than twenty millions, and there was not a railroad in the State of Kentucky. And yet people came here from all the New England and Middle States by the hundred. Edward Everett guided a party of New England school teachers here in the summer of 1847. They came by way of Pittsburg, taking a steamer thence to Owensboro, Ky., and then by stage a two days' ride—80 miles—to the Cave.

The hotel is here now practically as it was then, and one can easily believe that no new furniture has been added. From 1840 to 1870 scarcely a person of note then living but visited the Cave; it was a sort of finishing touch to one's education, and people who could not talk intelligently of Niagara Falls and the Mammoth Cave, had no standing in polite society.

Everett gave lectures at Harvard on the Mammoth Cave. Webster gave a great speech at the Cave in 1854, and Emerson, in his essays, several times refers to his visit here, telling of the fish that have no eyes to see. Barnum brought Jennie Lind here, and she sat in a stalagmite chair that is now proudly pointed out by the guides. From the year 1850 to the breaking out of the war in 1861, there were held over 300 conventions of learned societies, college alumni, and gatherings of prominent people from all over the world.

It is worth while to note the stern fact that even the wonders of creation do not actually attract any special attention unless some advertising man gets busy. The railroads really make Niagara Falls go. They are advertising it continually as a continuous performance, and filling people with a desire to go there, then transporting them for a consideration.

In 1869 the man who owned the Mammoth Cave died, and since then the Cave has been an orphan. There were 13 heirs scattered in different cities throughout the United States, all intent on spending the beautiful income that was forced upon them from this magnificent paying property.

Every person who went into the Cave paid \$2 for the privilege—it was a monopoly. People would come, of course; there was no other Cave to go in.

But soon the people ceased to come.

The advertising man was dead.

Humanity slipped back into indifference. They forgot to think of caves or gently pool-pooled them. Caves are not necessary to human happiness. Caves are not necessary until some man by astute advertising fills us with the desire to see them.

Copper in Chloride Solutions.

By GUSTAVE FERNEKES.

*During the winter of 1906-07, A. C. Lane, State Geologist of Michigan, requested me to make analyses of the waters of the Lake Superior copper mines for the purpose of determining whether these waters could in any way be connected with the genesis of the copper deposits in that region.

A series of analyses was made upon samples from various mines from depths ranging from 800 to 5,000 ft. It appears from these analyses that the waters are more or less concentrated solutions of calcium chloride, sodium chloride, and sodium bromide, with traces of sulphates. Furthermore, the concentration of these solutions increases with the depth. Upon reading an account of the very interesting experiments of Stokes in which metallic copper was precipitated from copper sulphate solution by means of ferrous sulphate, it occurred to Lane that similar results might be obtained when the chlorides instead of the sulphates of the above metals were used.

Preliminary experiments carried out according to the method of Stokes, however, gave negative results, that is, no copper was deposited. The cause of the failure is due to the fact that metallic copper is soluble in hot dilute hydrochloric acid, whereas dilute sulphuric acid which was set free in Stokes' experiments has absolutely no effect upon the copper. The following reactions, published by Lane, show the change which takes place:

1. $2\text{FeCl}_2 + 2\text{CuCl}_2 = \text{Cu}_2\text{Cl}_2 + 2\text{FeCl}_3$.
2. $2\text{FeCl}_2 + 2\text{CuCl} = 2\text{Cu} + 2\text{FeCl}_3$.

The ferric chloride is then hydrolyzed according to the following well known reaction:

3. $\text{FeCl}_3 + 2\text{H}_2\text{O} = \text{Fe}(\text{OH})_2\text{Cl} + 2\text{HCl}$.

Reaction 3 takes place at high temperatures and fairly dilute solutions. The reactions which take place in the experiments of Stokes are similar to the above. As he used the sulphates instead of the chlorides, free sulphuric acid instead of hydrochloric acid was formed.

As only traces of sulphates were present in the waters examined, and they are rare in the rocks and minerals of this region, more careful attempts to precipitate the copper from the chloride solutions seemed justifiable. To make the precipitation of copper possible according to the above reactions, the hydrochloric acid must be constantly neutralized. This neutralization can be brought about by the carbonates or silicates of calcium and sodium. Calcium hydroxide was first tried, then calcium carbonate, and finally calcium silicate in the form of the mineral wollastonite. The experiments were successful, the copper being deposited in from 10 to 15 minutes heating at 200° C.

Complete precipitation required a somewhat longer time. It is evident that the more soluble the neutralizing mineral is in hydrochloric acid the more efficient it is for rapid neutralization and consequent precipitation of the copper. It also seems probable that we would be able to obtain crystalline copper more readily if a slower neutralization took place than in the above experiments, where in fact the copper came down in a fluffy condition.

At this point Lane suggested the following minerals, common in this region, which may have taken part in the neutralization of the free acid: Labradorite, prehnite, laumontite, datolite, analcite, and pectolite. Of these minerals the first three were present in the rocks before the copper deposits were formed and the last three are closely associated with the metal. The first four minerals

were tried, but positive results were obtained only with prehnite and datolite. Since the conditions of the experiments, as finally carried out, were slightly different from those described by Stokes, it may be well to mention a few of the modifications introduced. Instead of employing a metal bath as did Stokes, an ordinary sand-bath was used. The thermometer was placed alongside of the sealed tube containing the solutions. As explosions are not frequent, this arrangement is perfectly satisfactory. The total length of the tubes employed was also greater, being about 18 in. The upper limb of the tube was surrounded by a water-jacket. The temperature of the lower limb ranged from 200° to 280° C. The material was introduced into the tube in the following order: First, about five grams of the neutralizing mineral, finely ground and freed from possible admixture of copper by treatment with nitric acid; then 0.2 grams of copper chloride; and finally a solution of ferrous chloride, containing an excess over that required to precipitate all of the copper. A few crystals of potassium bromide were also added. The solution, which was always slightly acid, due to the ferrous chloride, was then almost neutralized by the addition of sodium carbonate, filled to the top with water and sealed.

In the case of prehnite, perfect circulation of the liquid above the mineral continued for about five hours when heated to 200° C. At the end of this time the basic iron salt formed in the reaction covered the small surface of the exposed prehnite to the height of two to three centimetres and consequently further action proceeded very slowly. Occasional cooling of the lower limb of the tube was therefore resorted to, and by this means the solution was drawn back into the mineral, constantly exposing new surfaces. The tubes were heated intermittently for 10 hours during the day. The heat was removed in the evening and again applied the next morning. After heating the solution and prehnite in this manner for five days, an explosion took place at about 250° C. A portion of the side of the tube about five centimetres from the bottom was blown off, leaving a fairly hard cake underneath. On examining this cake of mineral with a small hand lens, it was found to be interspersed with shiny particles of crystalline copper. A few chemical tests were made. The particles were soluble in nitric acid with the evolution of brown fumes. They were insoluble in dilute hydrochloric acid, which fact distinguished them from cuprous oxide, and they precipitated metallic silver from neutral silver nitrate solution. The prehnite had become much darkened and the particles of the mineral were stained red in places with iron oxide.

Datolite was acted upon in a similar manner for six days, at the end of which time minute crystals of copper could be detected throughout the mass of the mineral. Experiments with laumontite and labradorite have up to the present time been unsuccessful and lack of time prevents me from carrying out more extensive researches in this direction.

It is not the object of this paper to draw any geological conclusions, especially as so few experiments have been performed. Nevertheless the work may be of value in reference to the genesis of copper deposits in the Lake Superior region. It is possible that hot solutions of copper and ferrous chlorides acted upon each other with the liberation of free hydrochloric acid as in the foregoing experiments. The hydrochloric acid acted upon the surrounding rock, consisting principally of calcium and sodium silicates, and a neutralization was effected. Simultaneously with this neutralization the copper was precipitated. Calcium and sodium chlorides were left in solution (mine waters), and silica was precipitated as quartz. Possibly the temperatures and pressures were far higher than those in the experiments.

*Abstracted from an article entitled 'Precipitation of Copper from Chloride Solutions by Means of Ferrous Chloride,' in *Economic Geology*, Vol. II, No. 6.

From these considerations one might expect that the relation of the calcium to the sodium would be the same as that existing in the original igneous rock. No such relation has thus far been determined. The analyses differ materially with the locality and depth of the samples.

The following analyses of typical mine waters show the relation of sodium to calcium with varying depths, the results being given in grams per litre:

It may be seen that the sodium in the upper level of the Centennial mine is in excess of the calcium, whereas in the lower level the quantity of calcium is about six times that of the sodium.

	I.	II.	III.
Cl	17.74	5.780	3.549
Ca	8.75	1.880	0.880
Na	1.49	1.584	1.287
Br	0.224
SO ₄	0.0123
Total	28.21	9.244	5.716

I. From Quincy mine, No. 6 shaft, 53rd level. Depth about 5,000 ft.

II. From the 20th level of the Centennial mine. Depth about 2,000 ft.

III. From the 11th level of the Centennial mine. Depth about 1,100 ft.

Although it is generally true that the calcium in the volcanic rock is considerably in excess of the sodium yet no average of a great number of analyses is available.

Results of analyses of traps are cited in Vol. 6, Part 1, of the Michigan Geological Survey. The amount of CaO varies from 7 to 10%, and the NaO from 3 to 5%. Further work along this line will be carried out when time permits.

RUST PREVENTIVE.—An option on the American rights to a patent process called 'sherardizing,' which it is asserted makes iron and steel rust-proof, has been sold to a firm in New York. It is claimed for this process that it coats iron and steel with zinc as well as or better than ordinary wet galvanizing, and that the iron and steel thus coated can be brilliantly polished. In the process, zinc dust is placed in a cylinder which has been brought to a temperature of 400 to 500° F; that is, below the melting point of zinc. The articles it is desired to 'sherardize' are put into the cylinder, which is then revolved. The zinc in this process is not actually melted, but forms an alloy through the surface of the articles absorbing the zinc, and then a coating covering the whole visible surface is deposited to any desirable thickness. Articles thus treated are said to have an even and adherent coating that wears excellently and does not strip, and which, by the use of a fine mop, are easily polished. It had been found that the use of the wet galvanizing process upon articles on which threads are cut made it necessary afterward to recut the threads. This, it is claimed, is obviated in the new process, thus avoiding both the additional work of recutting the threads and also making the threads themselves rust-proof. Another advantage claimed is that because articles are not heated to a high temperature the temper of the steel is little affected, while its tensile strength and that of iron remains the same. Aluminum and antimony can be substituted, it is said, for zinc, with success, while when copper and its alloys are subjected to this process their surface is so hardened as to even turn the edge of a steel tool.

VANADIUM STEEL.—The United Steel Co. is making vanadium steel in its 50-ton basic furnaces in a commercial way. Vanadium steel has never been made in the United States before except in experimental furnaces and in crucibles. The company recently made a heat of about 30 tons, which, it is stated, is the largest heat which has ever been made in America or elsewhere.

Furnace-Charging.

Written for the MINING AND SCIENTIFIC PRESS
By G. F. BEARDSLEY.

All blast-furnaces are sensitive as to the manner in which the charge is delivered into them. The managers of iron furnaces have put more study on this subject than the copper men and this has resulted in the production of efficient mechanical methods for feeding the iron furnace. On copper furnaces hand-feeding has been all but abandoned, giving way to so-called mechanical feeding. This usually consists in tipping the materials forming the charge into the side of the furnace from small cars having V-shaped bowls. So long as there is ample copper and sulphur for the matte-fall and the furnace runs all right the practice is good. Its faults obtrude only when ores low in those two elements have to be treated.

The following remarks refer to observations made at a copper plant where it became necessary, in the re-modeling of it, to provide for the handling of an increased tonnage. To that end small furnaces were discarded for those of a larger type. With the exception of the arrangement for the mechanical feed but little change was made in the furnace proper. The width was increased from 42 to 48 in. and the length, from 150 to 240 in. The 12-in. bosh in the two furnaces commencing 9 in. above the tuyeres were replaced by a 9-ft. straight jacket resting directly on the sole-plates and inclined outward at an angle of 7½°. Relatively, the number of tuyeres was increased and consequently the amount of air sent into the furnace was also increased. What proved to be the greatest change was the method of delivering the charge into the furnace. It was found that the angle and length of slope of the apron-plate, over which the charge was slid into the furnace, controlled the amount of sulphur burned or oxidized. The older furnaces were essentially hand-fed, that is, barrow-fed, and evened up or corrected by shovel-work. These furnaces had a comparatively short slope, the exact length of which is not to hand. In the new furnaces the slope was extended back, outside the line of the hood or top of the furnace, to a point where it would be under the lip of the V-shaped bowl of the charge-car when it was tipped over. The length of the slope was 4 ft. 2 in. and the angle of inclination 10°. As the ore slid out of the tilted bowl a separation took place. The coarse portions of the charge bounded down the long slope and plunging into the furnace, rolled down a central ridge to the side opposite the charge-car and brought up against the jackets. The finer material, meeting with a greater frictional resistance on the plate, ran more slowly and poured off the edge of the plate with just sufficient impetus to land in the centre of the furnace forming the above-mentioned ridge. The result was that the greater part of the blast came up alongside the jackets through the coarse material, leaving a central core, more or less dead. Slight raising of the charge produced the opposite effect, for when the central ridge was brought up a little, it acted as a dam; the charge backing up onto the slope of the plate and gradually sliding down as the charge sank put all the fine material against the jackets forming crusts. It was early found that the furnace had to be fed at just the proper height to avoid this crusting, though the crusts were fairly easy to bar off and were readily cut away by feeding an excess of sulphur ore when it could be spared.

The ores treated were naturally fluxed but they were so low in sulphur that there was at all times only barely enough of that element to furnish the required matte-fall. The ores had, in addition to the gold and silver, the following approximate percentage composition:

SiO₂, 31; Fe, 18; CaO, 18; Al₂O₃, 13; S, 3.3; Cu, 1.4.

In operating the old furnaces it was noted that when there was about 3½% of sulphur present, there was matte-fall enough to keep the slags between 0.3 and 0.4% copper and the matte between 40 and 50%. When the new furnaces were put in commission it was found that between 4 and 5% sulphur had to be maintained in the charge to get the same results in the slag and matte. Deficiency in sulphur gave high mattes and consequently high slags. A certain matte-fall was also necessary to keep the furnace in proper working condition. To supply the sulphur deficiency quite a quantity of poor pyrrhotite had to be obtained from an outside source. This, added to the charge, considerably increased the smelting cost.

Undoubtedly the new furnaces were oxidizing more than the old ones and a hunt was begun to find the cause. Suspicion was turned successively to the shape of the furnace, the increase in the amount of air sent in, the condition of the blast, the furnace feeders, the size and rotation of the charge components, and, lastly, the fall of the ore in the furnace. After observing the hand-feeding at one plant where they were doing cleaner work under poorer conditions and the mechanical feeding at another, where an entirely different method was in use, the general manager decided to hang two deflecting plates longitudinally in the furnaces, in such a position that the coarse part of the charge from each side would be dropped straight down and thus prevented from crossing it and lodging against the opposite jackets. Although the segregation took place on the slope much the same as before, there was a re-adjustment under the deflecting plates, equal in effect to, if not better than, the non-separation of the original coarse and fine material. The effect of the deflecting plate was immediately manifest in faster driving, increased matte-fall, lower grade of matte, cleaner slags, and a great reduction, or the cutting out entirely, of the amount of outside sulphur material and its replacement by a payable ore.

In the early days of lead smelting the smelters were prodigal of iron. Nowadays a premium is paid for it. A decade ago sulphur was not wanted in any ore and it was roasted to get rid of it. Under some conditions this is still being done. There are many places, however, where ores lean in copper and sulphur are being smelted and where 2% of sulphur is the difference between easy work and saving, and hard work and loss. More than ever must furnaces be suited to their work. Builders and designers of furnaces will do well to consider this point when the question of smelting ores low in sulphur is concerned.

The side feed on a sloping plate will always produce more or less of a segregation where there is a mixture of coarse and fine material. The separation producing open and tight areas in the charge, increases the oxidation of sulphur and cuts down the reducing effect of the coke. While the deflecting plate in this case overcame, to a large extent, a fault that was not or could not well be foreseen in the original design, it is not a good arrangement, inasmuch as it is more or less in the way, subject to considerable wear and tear, and to curling and warping by heat. The best arrangement for car-feeding a furnace is that designed by A. B. W. Hodges, general manager of the Granby smelter in British Columbia. This is a car run directly into the end of the furnace. In section it is roughly like the letter W with short straight sides on the wings and in the centre of the letter. In the hollow under the W is placed the truck, which runs on the floor-rails. At the four corners of the car, on the top edge are placed lugs also carrying small car-wheels. The latter engage a cast iron rail built into the brickwork on the inside of the furnace. The two tracks are so arranged

that as the car enters the furnace, the suspension rail engages the top wheels of the car and takes the load a little before the car leaves the floor-rails. There are two or three cars in the charge-train. At the ore-bins they are loaded by means of a long and short chute and the weights are adjusted by adding or removing a small portion of material. At the furnace a jerk of a rod in the hands of the feeder liberates any or all doors of the car as may be desired. The car-doors form the outside wings of the W and can be set to deflect the charge toward the centre or let it go against the walls of the furnace as called for by the condition of the top of the charge. The cars are in the furnace from one-half to three-quarters of a minute and out of the furnace from 8 to 15 minutes, as near as my memory serves. The motorman and a switchman operated the charge-train. There was a loader at the bins.

GLASS POLES.—Patents have been granted in Germany and other European countries and also in the United States, for an invention for the manufacturing of glass telegraph and telephone poles. A stock company has been organized and a factory for the manufacturing of glass poles has been built at Grossalmerode, in Germany. The glass mass of which the poles are made is strengthened by interlacing and intertwining with strong wire threads. One of the principal advantages of these poles would be their use in tropical countries, where wooden poles are soon destroyed by the ravages of insects and where climatical influences are ruinous to wood. The selling price of the poles has not been fixed yet, but the company is willing to accept \$6 for a pole 23 ft. long.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

W. W. C., of Galice, Ore., sends: No. 1, Molybdenite; No. 2, Chalcopyrite in quartz.

The specimen from Nevada City, marked S. C. L., is Galena with some Chalcopyrite.

H. A. McQueen, of Rebel Creek, Nev., sends a piece of Schist containing divergent Arsenopyrite.

The white mineral is Barite and the blue one Dumortierite in quartz, received from F. F. W., of Pacific Grove.

Rocks from Cumpas, Mex., marked Mpls, are: No. 1, Porphyrite; No. 2, contact metamorphic rock with Pyrite; No. 3, Porphyrite.

The pieces sent by J. P. P., of St. Louis, Mo., are: Barite, Tetrahedrite, and luminescent Sphalerite, described in this journal 1904 Vol. 88, p. 64.

Rocks sent by J. W. A., of Pioche, Nev., are: No. 1, Quartzite Breccia with a ferruginous cement. There is no evidence that it is volcanic. No. 2, Kaolin.

The specimens from Rawhide, Nev., marked G. M. A., are: No. 1, Quartz with Limonite; No. 2, Quartz with auriferous Pyrite; No. 3, Quartzite with Pyrargyrite.

W. B. H., of San Francisco, sends No. 1 to 3, Serpentine with native Copper; No. 4, impure Serpentine with oxidized Pyrite; No. 5, Talcose Schist with bands of Pyrite.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

PIPE-WRENCH.—No. 868,126; Joseph E. Richards, Melrose, and Charles W. Walker, Boston, Mass., assignors to Ireland Pipe-Wrench Company, Portland, Maine.

A pipe-wrench constructed of a tubular-handle; a chambered-shank in continuation of and in one piece with said handle; a pipe gripping-jaw fixed at the outer end of said shank; a pipe-gripping jaw fulcrumed on said shank; a rod at one end-portion pivoted on said fulcrumed-jaw and at its other end-portion entered into said tubular-handle; a head rigidly fastened to said rod within and loosely fitting the bore of said handle; a coiled-spring confined end to end between said head and a shoulder at one end of the tubular-handle, and a lever fulcrumed on the chambered-shank and at one end-portion straddling the said rod lying there-within, and arranged for a bearing at its opposite sides on shoulders of said rod, all as particularly described and for operation as specified.

METHOD OF EXCAVATING ROCK TUNNELS.—No. 868,259; Patriek Ford, Chicago, Illinois.

The method of excavating rock tunnels comprising first constructing an under heading for the length of the tunnel and then arranging the air and the pipe lines close to the wall of the heading then throwing down the material from the roof of said tunnel into said heading and operating at either or both ends of the tunnel.

DREDGING APPARATUS.—No. 867,984; Simon Lake, Bridgeport, Connecticut.

A dredging apparatus, comprising a submergible tube, having a working chamber at its lower end, and a suction apparatus arranged in connection with and operable from the working chamber and adapted for delivering material to the upper end of the tube through said tube.

BLAST-FURNACE-CHARGING DEVICE.—No. 868,506; Charles P. Turner, Harrisburg, and John W. Dougherty, Steelton, Pennsylvania.

In a furnace-charging device, the combination with a buggy of a bucket, a rigid suspension for the bucket, means to mount the suspension in the buggy to swing, and devices to selectively rotate the bucket about a vertical axis.

ORE-TESTING TABLET.—No. 868,270; John E. Hunsinger, Saginaw, Mich., assignor to Earl A. Cheney and Frank Cheney, Saginaw, East Side, Michigan.

An ore-testing tablet, comprising powdered, hard-wood charcoal fifteen parts, chlorate of potash eight parts, sodium carbonate six parts, said ingredients being bound together by a suitable adhesive. An ore-testing tablet comprising a fuel, an agent rich in oxygen to enhance combustion, and a combustion retarding agent and flux.

FAN-VENTILATORS.—No. 868,206; James W. Miller, Gillespie, Illinois.

The combination in a fan for the purpose described, of two cone-shaped hub sections arranged with their large portions inward and adjacent to each other, an annular central disk fixed between and extending radially from the inner large portions of the hub sections, annular side rims, angle bars fixed to opposite sides of the central disk and having inner straight portions disposed radially to the centre of the fan and also having outer portions curved outward and rearward, with reference to the direction in which the fan is rotated, correspondingly arranged and shaped angle bars fixed to the inner sides of the side rims, and radial blade sections located at opposite sides of the central disk and fixed to the angle bars on the disk and side rims and having their outer end portions curved rearward, with reference to the direction in which the fan is rotated.

A Rapid Calculator.

The accompanying illustration shows a new device for the rapid calculation of the various functions and dimensions of hydraulic pipe-lines. It was designed by Rudolph W. Van Norden, of San Francisco.

There is probably more uncertainty as to the exact behavior of water, with the accompanying losses by friction, change in velocity, direction, etc., than in any other branch of practical engineering, and many formulas have been worked out, none of them, however, fulfilling all the conditions required. The development of power for all purposes from high waterfalls, entailing great pressures, has enormously enlarged the use of riveted sheet iron and steel pipe, especially on the Pacific coast.

The formula on which the working of this computer is based was developed as the result of a large number of tests on pipes, varying greatly not only in the pressure applied but in size and length. It is accurate for all ordinary conditions.

There are two movable dials, a movable sector, and a stationary dial. With these, eight factors are determined, pro-

In the illustration the lines showing the different dials do not show distinctly owing to the fact that the dials are cut out of blank card stock and will not photograph readily. The window in the dial for theoretical horsepower does not show, but the general appearance of the device is well shown.

vided any two are known and one assumed. These factors are: Diameter; thickness of metal; weight per foot of length; static head; quantity of flow, in second-feet; friction head; velocity of flow; theoretical horsepower of the water.

The scale of flow, in cubic feet per second, is on the larger dial, 6 in. diam., arranged to coincide with that of the friction head, on the small dial, 5 in. diam., the latter being drawn to one-half the logarithmic unit dimension of the former. When the initial points of both scales are placed so as to coincide, the numbers on the lesser scale are the squares of the corresponding numbers on the other scale. Through a window in the small dial, under the friction head scale, is shown a scale of the diameter, drawn on the large dial. These three scales are proportioned so as to represent graphically the friction head formula used.

A scale showing the static head is also drawn on the small dial, and when placed in contact with the proper value on the flow scale shows the theoretical horsepower through a second window in the small dial (not shown in the cut), by a scale drawn on the large dial. This is a simple multiplication in the first power, arranged with a constant.

On the stationary dial, in contact with the scale of flow, is a second scale of the diameter and also one giving the velocity of flow, this last value varying directly as the flow and inversely as the square of the diameter.

On the outer circle of the stationary dial are two concentric scales, one showing the proper thickness of metal,

using a factor of safety of $4\frac{1}{2}$ and a tensile strength of 50,000 lb., and the other the weight per foot of the completed pipe at the thickness determined. The two scales are operated by a sector having a curved edge, based on the graphical representation of the static head, various values of which are also shown on a logarithmic scale. The contact, of a value of the static head, with one of diameter, determines the thickness. A series of curved lines, joining points of similar weight of the various sizes of pipe, terminates in a scale of weights; the curved line denoting the weight should be selected as the one coinciding with the intersection of the curved edge of the sector and diameter.

The scale of friction head is carried to 1,000 ft. to allow for calculations for the flow of water from pumps. The pressure required to force a given quantity of water through a given length and size of pipe can be instantly determined by finding the friction head for the total length and adding to it the static head on the pipe. This method does not, however, provide for sharp bends or entrance friction.

Long cast iron and wood-stave pipes may be calculated for flow, diameter, velocity, and friction head. In the former, however, the values of friction head, where the pipe has a diameter less than 16 in., are less than those given by the computer, or in other words, the quantity of flow for a given friction loss is greater. The proper constants are, however, tabulated so that the calculations for the smaller sizes may be made. The friction head of wood-stave pipe is from 50 to 70% of the values given, depending on whether the pipe be old or new, but the use of these constants for wood pipe will give results somewhat less than those derived by Kutter's formula, where n is taken as 0.010 for pipes from 12 in. up, and this difference increases as the diameter increases, until for 24 in. it amounts to 35% and for 48 in. to 50% of the higher value.

This method therefore computes the flow for large wood pipes greater than that determined by the Kutter formula method for a given friction loss.

A page of directions accompanies the instrument, clearly showing the various operations, and with a little practice the operation will be found to be as simple and as accurate as the slide rule. The calculator is bound in a neat board cover. The dials are made of the best quality of bristol board, reinforced on the back with muslin, while the surface is finished with a waterproof varnish, which can be washed if soiled.

In the accompanying cut the computer is set to work the following problem: Given a flow of 11 cu. ft. per sec., head of 500 ft., and assume a diameter of 16 inches.

The line showing 500 ft. on the sector is placed to coincide with that showing a diameter of 16 in. on the stationary dial. The large dial is then revolved so that the number 11 on the flow scale will also coincide. Place the pointer for diameter at the window in the small dial at 16 in. of the second diameter scale. In contact with the line of flow, head, and diameter is the friction head, which in this case is 1.6 ft. per 100 ft. of pipe. The pointer at the lower side of the large dial shows the velocity of flow, which is 8 ft. per second. The pointer on the sector gives the thickness of metal, which is $\frac{5}{32}$ in. Following out the curved line which coincides with the intersection of the diameter line and the edge of the sector, gives the weight per foot of the finished pipe as 30 pounds.

To get the theoretical horsepower in the water, the small dial must be revolved until the number in the second, head in feet scale, which in this case is 500, coincides with the number 11 in the flow scale. Through the second window in the small dial may then be read the answer, 640 horsepower.

It will be readily seen that any other two quantities might have been the given ones and that any third quantity may be assumed.

THE RISDON IRON WORKS has completed the shipment of an order of 70 Risdon-Johnston concentrators to the Moctezuma Copper Co., at Nacozari, Sonora, Mexico. This order constitutes the entire vanner equipment of the new 1,200-ton mill now building by the Moctezuma Co., and was secured as the result of a long competitive test.

Editorial.

ON ACCOUNT OF the peculiar financial conditions and the consequent series of legal holidays, it has been deemed advisable to postpone the convention of the California Miners' Association, announced for November 25. The date of meeting will be stated a few weeks hence when the executive committee considers the conditions more favorable to a good attendance.

FURTHER LETTERS in reply to the questions involving professional customs appear in this issue. One of the letters is from a representative firm of mining engineers in England. We expect to publish several more contributions on the same subject, for it has evidently aroused keen interest. When the replies have all appeared, it will be time enough to offer further comment.

WE TAKE PLEASURE in giving our readers a scholarly article by Mr. Ernest A. Hersam, professor of metallurgy in the University of California. The economy of power in crushing ore is important to all managers of mills and smelters, and we expect that the discussion of the fundamental problems underlying so practical a matter will commend itself to engineers.

THE TEST to which the Trust Company of America was subjected during the recent panic at New York affords a striking commentary on financial conditions. In the course of two weeks this banking institution paid out no less than \$31,000,000 to its frightened depositors. This run is unprecedented in the history of banking and ought to establish the Trust Company of America securely in the confidence of the public.

THREE OF THE TRUSTEES of the State Mining Bureau have resigned, namely, Curtis H. Lindley, F. W. Bradley, and E. A. Stent. Only two—Louis Janin and Harold T. Power—remain. The resignations are due to the fact that the trustees find themselves in a false position, being used chiefly as an auditing committee to pass upon expenditures over which they have no control.

CONGRESS is to be asked to release the miner from the legal necessity for doing assessment work on his claim, so that the expenditure of \$100 in work may be avoided. It is stated that this will "relieve the miners and prospectors of a great burden at a time when such relief will be most appreciated." We question the advisability of this step. While, of course, desirous of supporting any act likely to benefit the miner or the community in which he lives, we regard this suggestion concerning assessment work as mainly in the interest of

questionable mining companies that have acquired control of a large number of unpatented claims on which the proper work of mining has not been done. The real miner and prospector has done his assessment work by this time, and, if he has not, the financial stringency will not deter him, for his credit is unimpaired. On the other hand, there are wild-cat companies and speculators that have sold stocks and interests in unpatented claims, never intending to do any work but hoping to make a turn before the annual requirement became due. Such people will suffer, and if they do not, the public will, assuredly. The congressmen and newspapers that advocate this abrogation of assessment work are playing to the gallery.

ON ANOTHER PAGE will be found a statement made by Mr. R. B. Lamb, explaining his connection with the Barnes King Development Company, which came to grief recently. It appears to be another case of an engineer's advice being set aside because it interfered with the plans of promoters. The members of our profession will be glad to absolve Mr. Lamb of all blame. If there be a lesson to be drawn from the episode, it is to resign from the service of a client that disregards the advice he pays you to give him. People that run counter to their consulting engineer's advice are either knaves or fools, usually the former.

IN the London *Mining Journal* just to hand we note a long letter from Mr. James Darroch referring to charges of gross plagiarism brought against him in that journal by Mr. L. Parry. One of the charges concerns an article sent to us by Mr. Darroch and appearing in our issue of January 19. Into the merits of the controversy we do not care to go, but we note that Mr. Darroch insists that "reputable papers do not publish personal attacks, and it is their usual custom to send the person assailed a copy of any criticism received, so that he may reply to it in the same issue." To this the editor of the *Mining Journal* replies, saying that such a statement "only requires formulating for its absurdity to be apparent." Mr. Darroch is right and the editor at London is wrong—absolutely and completely. As an instance in point we remember that in 1895 Mr. E. J. Dunn, now director of the Geological Survey of Victoria, was charged with having stolen the ideas of a Mr. Nicholas in regard to the geology of Bendigo and the attack appeared in the form of an anonymous letter published by the London *Mining Journal*. As Mr. Dunn probably would not see it and certainly could not reply to it under several months, I undertook to defend him, knowing him and Bendigo intimately. Mr. Dunn's present position and reputation refute the calumny, but a younger and less known man might have suffered severely from the imputation. Certainly any reputable journal should—and usually does—permit a man whose character is assailed to reply to the accusation in the same issue as the one containing the attack. The very fact that mining engineers are so nomadic that they may not be able to protect their honor when thus assailed is the more reason for going slowly in such matters.

Wall Street.

THE FINANCIAL NERVE-CENTRE of this continent is situated on a narrow street running from lower Broadway to the estuary separating New York from Brooklyn. As a symbol of the speculation underlying the larger part of modern industry, Wall Street has become the expression of relentless materialism and selfish greed, until to many well-meaning people it is a complex of Monte Carlo and the pawnshop, of the highway and the arena, of the devil and the deep sea. Away from New York, on the farms of Nebraska or among the mines of Colorado, this Wall Street is spoken of as something utterly wicked and hopelessly unregenerate. Populist orators may be responsible for such a slander, but there are reasons less superficial. Certain it is that no one is more surprised at the unfriendly opinions of such provincials than is the banker or broker whose whole soul is in the great game that is played where Nassau, Broad, and Wall streets come together—the ganglion of a tense nervous system whose twitchings convulse the markets of this continent from New York to San Francisco, from Montreal to the city of Mexico.

Let us analyze this prejudice against Wall Street. Is it merely the expression of ignorance or due to a jealousy of those that pull the strings? Is it only the sneer of the disgruntled or the vaporings of a discontented mind? We think not. To us there is a basic reason for the attitude assumed by the majority of people in the West in regarding Wall Street as the epitome of sinister speculative activity. We share it ourselves; for the following reasons:

Wall Street absorbs too much of the productive energy of the country. Thus, take a community like Denver or Salt Lake: There you have a population of, say, 100,000 to 200,000 and the distributing centre for a mineral and agricultural region of varied resources. Among the citizens there are a number of men distinguished for wealth and initiative. If a new goldfield is discovered there are always a few such men able and willing to buy the prospects and make them mines, by spending money in exploration and equipment. If an agricultural experiment is to be made, by irrigation or the cultivation of a new product, such men are ready to take the risk of starting the fresh enterprise. If branch railroads are required, they supply the capital; if public utilities need to be financed, they come forward. We speak of the kind of man that is responsible for the industrial development of America, real captains of industry, not *chevaliers d'industrie*, but men of marked originality, broad imagination, and invincible courage, those that *do* things. This type of man means much to a people engaged upon the industrial conquest of a continent. But this is the kind of man that Wall Street entices, engulfs, and spues out—broken and worthless. For, finding that money can be made faster and more easily by buying mining stocks than by developing mines, such men cease to devote themselves to the creative side of industry and become mere gamblers; they leave the West and stay at the Waldorf. Other men, who built railroads and were

discovered to have unusual executive ability in the administration of a great system of transport, also abandon the career in which they were of such obvious usefulness in order to speculate in railroad stocks; they no longer build railroads, they help to wreck the companies controlling them; at the best they end in ruining themselves, if not financially, at least as productive members of the community. It is not necessary to expand the theme by referring to other examples of misdirected energy. The general result is that a distressingly large proportion of the pioneer type of man, the men that blaze the trail of industry and lead the way in every sort of beneficent endeavor, are taken away, to become essentially unproductive speculators. From the provincial town they go to the financial centre, from the factory to the hotel, from the mine to the bucket-shop. In short, Wall Street absorbs too many of the dynamic men of America.

We venture to say that the brains and ability wasted upon betting on stocks on Wall Street would more than suffice to run the continent of Europe and administer successfully the political and financial affairs of every monarchy and republic from the Ural mountains to the Irish sea. Of course, speculation in stocks is considered a finer occupation than betting on the red and black, but it is no more productive of tangible results, and, for ourselves, we think it nowise different, save for the larger issues involved. Every hamlet in the mountains, every town on the plains, sends a few of its shrewdest, most energetic, and most forceful—its dynamic—men to Wall Street every year. They are as lost to productive industry as if they were swallowed in a maelstrom. Of course, we know that they originate schemes, they underwrite the finances of fresh undertakings, they set going new enterprises that create prosperity for all of us—so says the apologist. But, having lived in New York and stood on the edge of the crater, we are little inclined to accept such an explanation of the bubbling and the turmoil, the fume and the steam, that issue daily from the depths, making the earth tremble and the blue sky alternately black with gloom or bright with the flashes reflected from the cauldron below. Middlemen we must have, promoters too, and brokers; that is well enough, but we are protesting against turning natural pioneers into middlemen, leaders into besotted followers, engineers into stock-jobbers. Think of the stimulus to industrial progress, possibly even to something higher, if about two-thirds of the brilliant and intensely forceful men now congregating on Wall Street were released from the menagerie of bulls and bears to return to the mines and farms, the railroads, and the factories of this country, to give to it once more the native intelligence and the uncommon ability that is now devoted to a financial catch-as-catch-can. When a strong skillful miner quits work to play faro or roulette, we call him vicious, we regret the loss of a fine workman, we note the degradation of a good citizen. The camp needs such men to develop its mines, and the town will suffer by the diversion of such a unit of energy into an unproductive channel. A useful man has become a useless gambler. The

reasonableness of such a view of the matter may not be obvious to everyone, but such is the mental attitude of the West to Wall Street.

Mining Location by Deputy Mineral Surveyor.

ON SEVERAL OCCASIONS in response to inquiries from subscribers, we have attempted to give in these columns the then state of decision as to the right of a deputy mineral surveyor to make a mining location. It had been there noted that the Land Department had changed its rulings frequently and that the question seemed to be still subject to debate so far as departmental decisions were concerned. As to the State courts, the Supreme Court of Utah had held that a mining location made by such deputy was void from its inception and no title could be obtained through it by a third person. It was also observed that the Supreme Court of the United States, having the opportunity to pass upon the question, neglected to do so, leaving it practically unsettled. The other Federal courts have not as yet spoken. We have now to note two additional contributions to the literature of the law, one by the Secretary of the Interior and one by the Supreme Court of the State of Nevada. These may be briefly outlined.

Sigmund K. Bradford, a deputy mineral surveyor for Nevada, located certain placer claims near Tonopah. His action was reported to the Commissioner of the General Land Office by a special agent, and, after hearing, an order was entered by the Commissioner directing the revocation of his appointment as deputy. On appeal to the Secretary of the Interior the revocation was upheld on the ground that the law inhibited locations by deputy mineral surveyors, and that, in making the location in question, Bradford was guilty of a violation of the law and incurred the penalty of dismissal. The validity of the location was not directly passed upon, although the inference is obvious that if it had been before the department for adjudication, it would have been held to be invalid.

The Supreme Court of Nevada in the case of *Cook v. Hand*, in a majority opinion recently filed (Judge Talbot dissenting), reached a conclusion diametrically opposed to the ruling in the Utah case and to the conclusion reached by the Secretary of the Interior in the Bradford case (although the Court had no knowledge of the Secretary's ruling in the latter case). The Nevada court holds that deputy mineral surveyors are not disqualified from making mineral locations and that such locations, when made, are valid. The processes of reasoning by which the divergent conclusions are reached are interesting only to the lawyer and metaphysician. Courts of other jurisdictions, in passing upon the same question, have their choice of precedents. Until the Supreme Court of the United States speaks on the subject deputy mineral surveyors will undoubtedly refrain from making locations; otherwise they will lose their appointments. The rule in the Bradford case will unquestionably be enforced by the Secretary of the Interior against all deputies who attempt to make locations.

By the Way.

Owing to the record established by the *Lusitania*, which crossed the Atlantic in 4 days 20 hours and made 617 knots or 740 miles in one day, the following account of this vessel, from *Engineering*, will be of interest:

The *Lusitania* is a most encouraging success. It is not so much that her preliminary trials promise the realization of the contract condition that she shall make a double voyage on the Atlantic between Liverpool and New York at an average speed of $24\frac{1}{2}$ knots within a year of her entering the service—this is gratifying in the highest degree—but the success carries a greater significance. Although the vessel certainly marks progress in marine construction, she must, further, be regarded as a pioneer—as beginning a new era. This is because of the adoption and success on a huge scale of the steam-turbine as a ship-propelling engine. Other vessels, it is true, are now run by turbine-driven screws; but when the system was decided upon for the *Lusitania*, the experience with this type of engine on a large scale was limited, and particularly so as regards durability. The confidence of the owners and builders of this ship, now justified, gives promise that the future will see greater developments. We find that each successive generation has had at command almost equal mental activity and mechanical ingenuity, with the important addition, that lapse of time brings accumulated experience, to enable higher results to be achieved. The problems are now greater, if more clearly defined by reason of our more exact scientific knowledge; but the encouragement afforded by past successes is also greater; and thus there is no reason to suppose that the *Lusitania* will be other than a stimulant to greater effort to surmount new difficulties and sweep away new obstacles which beset the path of progress in the most fascinating of all branches of applied mechanics—the rapid, comfortable, and safe transportation of passengers across the seas, often turbulent and ever resistant, which separate the increasingly friendly nations of different continents.

DIMENSIONS AND GENERAL DATA.

Length over all.....	785 ft.
Length between perpendiculars.....	760 ft.
Breadth, molded.....	88 ft.
Depth, molded.....	60 ft. $4\frac{1}{2}$ in.
Gross tonnage.....	32,500
Draught.....	33 ft. 6 in.
Displacement.....	38,000 tons
Number of passengers—first.....	552
“ “ second.....	460
“ “ third.....	1,186
Type of engine.....	Parsons turbine
Number and type of boilers.....	25 cylindrical
Number of furnaces.....	192
Steam pressure.....	195 lb.
Total heating surface.....	158,350 sq. ft.
Total grate area.....	4,048 sq. ft.
Total indicated horsepower.....	68,000
Speed.....	25 knots
Coal for voyage to New York.....	5,000 tons
Cargo carried.....	1,500 tons
Coal per 1. hp. per hour.....	1.45 lb.

One important feature in fixing the designs had reference to the use of the ships as cruisers or scouts in time of war, and the machinery—which is almost entirely under the water-line—has been so disposed in separate compartments, and with coal protection along each side, as to counteract, as far as possible, the effect of the enemy's fire at the water-line. For purposes of attack the *Lusitania* will be provided with an armament as satisfactory as the armored cruisers of the County class, because on one of the topmost decks there will be carried, within the shelter of the heavy shell-plating, four 6-in. quick-firing guns attaining a muzzle energy of over 5,000-ft. tons, while on the promenade-deck on each side there will be four more guns on central pivot mountings,

also able to penetrate $4\frac{1}{4}$ -in. armor at 5,000 yards range, and 6-in. armor at 3,000 yards range. With the great speed, which can be maintained for three or four times the period that any modern cruiser can steam even at only 21 knots, and with the careful subdivision for protection and their satisfactory offensive power, the *Lusitania* and her consort may be regarded as most effective additions to any fighting squadron.

The rudder and steering-gear are all placed well below the water-line. This is a most important point in respect of protection, should these vessels be ever impressed into the national service. The stern has been suitably shaped in the *Lusitania* to enable this object to be accomplished satisfactorily.

The adoption of four units of machinery and four screw-propellers enabled the machinery to be made in two completely separate sets, one to starboard and the other to port, just as in a vessel with twin-screw reciprocating machinery; a distinct advance upon the triple-screw arrangement in former turbine ships, where such complete independence is unattainable. The division of the power into two complete and independent systems follows the course pursued for so many years in the Royal Navy, whose lead is now so generally adopted in this respect in the mercantile marine. It has in this case enabled the engine-rooms to be well subdivided by watertight bulkheads, and the advantages in general secured have been obtained without the sacrifice of a single point of any importance.

In the form of stern devised to improve the manœuvring, the dead wood was cut away. As in earlier Clydebank ships, the rudder, of the barn-door type, is supported for about two-thirds of its depth. Immediately forward of it, on each side, are the two inner propellers, the shafting for these being entirely borne within the ship, the framing of which was bossed out, and strongly supported by heavy webbing. The forward propellers are about 70 ft. ahead of the inside screws, and here also the frames are carried by heavy webs. Owing to the great beam of the ship, and the very fine run, the blades of the outside propellers do not project beyond the beam-line, while, at the same time, all the propellers work in free water, and provision has been made for a satisfactory clearance between the propellers and the skin of the ship. The calculations of stresses were carried out in the usual way, on the assumption that the material of the hull, if built of mild steel, should not be subjected to a stress exceeding 10 tons per sq. in., and on the basis that the vessel might experience the hogging and sagging stresses consequent on meeting with waves of her own length, and of a height from the trough to crest of one-twentieth of the length of the wave. The very careful series of calculations entered into showed that the maximum bending moment was slightly over 1,000,000 ft.-tons.

COMPARATIVE TABLE OF OCEAN LINERS.

Name.	Date.	Length, ft.	Displacement, tons.	1. hp. of engines.	Speed, knots.

Lusitania.....	1907	785	45,000	68,000	25

The *Lusitania* affords accommodation for 510 first-class, 460 second-class, and 1,200 third-class passengers. There are 717 rooms. Elevators are provided. There are eleven of these, all worked by the electric current supplied by the ship's generating plant. They travel through a height of 36 ft. between decks.

Personal.

ARTHUR L. PEARSE is here.

POPE YCATMAN is at Ely, Nevada.

F. P. KENNEDY is at Treadwell, Alaska.

JOHN B. FARISH has returned to Denver.

E. GYBSON SPILSBURY is at Guanajuato.

ALBERT BURCH has returned from Grass Valley.

ALFRED JAMES is at El Paso, on his way to Mexico.

HARTWIG A. COHEN was at Nevada City during the past week.

C. E. BOGARDUS, of Seattle, was in San Francisco this week.

WM. H. SPAULDING is here on a visit from Rhyolite, Nevada.

J. H. CURLE writes from Ceylon, on his way to Mandalay.

J. GORDON HARDY is returning to El Paso from San Francisco.

CHARLES H. LYSER has returned to San Francisco from Costa Rica.

J. POWER HUTCHINS has been examining dredging ground in eastern Oregon.

ELY HUTCHINSON is attending the session of the American Mining Congress at Joplin.

ARTHUR L. PEARSE was here on his return from Alaska, and is now at Phoenix, Arizona.

H. R. PLATE has been appointed manager for the Consolidated Copper Co., at Ely, Nevada.

E. M. RAY, consulting engineer for T. N. Barnsdall, of Pittsburg, was in Chihuahua last week.

JOHN F. ALLAN has been appointed general manager for the Caucasus Copper Co. in Asia Minor.

H. S. ALLEN is assayer with the Bagdad-Chase Gold Mining Co., at Soulsbyville, California.

ROBERT WISNOM, mill superintendent for Chas. Butters & Co. at Virginia City, is in San Francisco.

WALTER G. GEDDES has been appointed general manager for the Daisy Mining Syndicate in Nevada.

J. A. HARTLEY is at work in the Garvin Cyanide & Development Co.'s laboratories at Los Angeles.

NOEL BARBER broke his leg in an accident underground at El Oro, Mexico. He is recovering satisfactorily.

PHILIP R. BRADLEY is here on a holiday from British Guiana, where he is superintendent of the Peters gold mine.

JAMES D. STEWART, superintendent of the United Water & Power Co., is on a visit to San Francisco from Gold Run.

H. P. GARTHWAITHE, resident director of Butters Salvador Mines and Butters Divisadero Co., has arrived in New York.

B. L. FARRAR, formerly of Colorado, is superintendent of the Chihuahua Mining Co. at Santa Eulalia, Chihuahua, Mexico.

OTTO STAHELMANN, of Salt Lake, formerly connected with the Anaconda Copper Co., is general manager for the Canadian Smelting & Refining Co. at Sault Ste. Marie, Ontario.

Obituary.

CLERMONT LIVINGSTON, general manager for the Tyce Copper Co., died on October 20 at his home on the Koksilah river, on Vancouver Island, B. C. He succumbed to bronchial pneumonia after a week's illness. He was born at London in 1850. Fifteen years ago he organized the company that purchased the Tyce mine, and became the moving spirit of that copper mining enterprise. He is survived by his wife, three sons, and two daughters, one of whom is the wife of E. C. Musgrave. In British Columbia Mr. Livingston was highly respected, as an honorable and capable manager, a man of sound judgment and fair in all his dealings. His sudden death will be mourned by many, both in Canada and England.

General Mining News.

ALASKA.

W. R. Rust, president of the Tacoma Smelting Co., was elected president of the Northwestern Commercial Co. to succeed John Rosene. Among other companies controlled by this company are the Northwestern Steamship Co., which runs steamers between Tacoma and Alaskan ports, the Northwestern Development Co., which owns and is developing mining properties near Copper river and Katala, the Copper River & Northwestern Railroad Co., which is building a line from Katala to Valdez, via Copper Center, and the Northwestern Siberian Co., which holds concessions from the Russian Government for mining properties in Siberia.

ARIZONA.

COCHISE COUNTY.

The Copper Queen Consolidated M. Co., through its manager, Walter Douglas, has announced that beginning Nov. 10 the wages will be reduced to the scale prevailing prior to Nov. 7, 1906, when the wages were raised 50c. per day.—Byron M. Pattison, superintendent of both the Shattuck and the Denn mine, has announced that these mines will shut down. The Shattuck-Arizona shipped ore to the Copper Queen smelter at Douglas prior to the slump in copper; when the Copper Queen Co. closed down two of its furnaces, it refused to receive any more ore from the Shattuck; then the Shattuck shipped its sulphide ore to the Old Dominion smelter at Globe while the oxidized ore was held at the mine. Two weeks ago the Old Dominion smelter refused to receive more ore. As the Shattuck has much development done and much ore blocked out the company decided to close down instead of doing more development work.—The Copper Queen and the Calumet & Arizona continue to work full-handed; most of the men are working on development, as this had fallen far behind during the past year owing to the scarcity of labor during prosperous times and the necessity of putting most of the men to work in the stopes. Besides these companies were rather short of miners when the strike was first declared by the Western Federation of Miners.—A shaft is being sunk on the Badger claim near Paradise; this shaft, which is now 50 ft. deep, is being sunk in the limestone near the porphyry intrusion.—The drift on the vein driven from the adit at the Smith's Springs property, which is a short distance southeast of the Badger shaft, is still in good ore. This drift is now 60 ft. long. Much water is flowing from this drift.—At the Savage property more miners were put to work last week. The Snowball shaft is still in good ore; development has been begun by this company on the Little Eva claim which adjoins the Snowball on the northwest.

GILA COUNTY.

Wages were reduced by the Old Dominion Copper Mining & Smelting Co. to the schedule in effect prior to Nov. 7, 1906. This reduction became effective Nov. 5. At present the Old Dominion is working only five days a week.—A rich vein of copper ore has been found on the 210-ft. level of the Independence mine, on upper Pinto creek. This vein is 2 ft. wide and carries about \$8 in gold and silver besides the copper. A 4-ft. vein of concentrating ore has been found on this level. The shaft is being sunk deeper. This property is near the Cole & Goodwin property and about four miles from the Gibson mine, where a strike of good copper ore was made some time ago.

GRAHAM COUNTY.

All the mining companies in the Clifton-Morenci district adopted a new wage scale on Nov. 1. As yet the wages of the machinists, blacksmiths, and boiler-makers have not been reduced. Most of the carpenters, whose wages were reduced 32c. per day, have quit work. The miners and millmen have accepted the reduction.—The wages of the miners at the Arizona Copper Co. properties have been cut 25c. per day. Concentrator No. 5 at Morenci has been shut down and 300 men at the mine and reduction works have been laid off on this account. The No. 6, or Long-

fellow, concentrator is running with a full force. The cut in the millmen's wages was 25c. and 50c. per day. The reduction of wages at the smelter was practically the same.—Similar cuts were made by the Shannon Copper Co. The output of the Shannon smelter for October was 1,536,000 lb. of blister copper. The new 1,000-ton furnace is working finely and is smelting at full capacity.—The output of the Arizona Copper Co. for October was 2,876,000 lb. of blister copper.—There has been no laying off of miners at the property of the Gold Belt D. & R. Co. The shaft, which develops the copper orebody, is now 200 ft. deep. The shaft, developing the gold-bearing vein, is also 200 ft. deep. Driving is being done on the 100-ft. and the 200-ft. level from this shaft. Sufficient water has been cut in this shaft to supply a good-sized mill and the company is rejoicing over the fact.

PIMA COUNTY.

The Twin Buttes has shut down and only the pump is kept running. The mine is said to be looking well and the shut-down is due to the slump in copper. The Calumet & Arizona people are still working on their property near the Twin Buttes. The Mineral Hill Consolidated has shut down as has also the Paymaster.—The force of miners at the Old Pueblo mine has been increased and much development work is being done at the mine. High-grade ore has been cut in the new shaft started on the Quien Sabe. This shaft is 25 ft. deep at present. A new road has been built from Tucson to this mine. The company intends soon to begin regular shipments to the smelter.

PINAL COUNTY.

The main shaft at the property of the Calumet-Pinal M. Co., at Owl's Head, 16 miles north of Red Rock, is 165 ft. deep. The drift on the 130-ft. level is in ore. Only a small force of miners has been working at the property since the slump in copper.

CALIFORNIA.

BUTTE COUNTY.

About seven miles southeast of Buck's ranch August Benner and H. G. Greenbower are driving an adit into Mount Arratt ridge on the slope facing the Middle Fork of Feather river. This adit is 250 ft. long; in a raise made at that point gravel was struck at a height of 10 ft., but, as it does not carry enough gold to pay for working, they are going to drive the adit farther in order to catch the deep channel.—Development work is being pushed at the Blue Lead mine where 10 men are working. This property is being developed by the Selbys of the Selby Smelting Co. A drainage adit is to be driven from the Kentucky ranch to cut the channel and so save the large expense due to pumping.

KERN COUNTY.

The Yellow Aster mill is treating about 500 tons of ore per day.—Considerable leasing is being done at the mines near Randsburg.—At the old Pathfinder group of claims on Fremont Peak, 15 miles from Randsburg, four men are working. These mines were re-located by B. F. Race some time ago, and are now called the Newlands group. H. C. Register, of Los Angeles, has bought a two-third interest and is developing this property. Some good ore has been struck in the new shaft that is being sunk.—Owing to the present financial stringency on the first of the month the tungsten mine at Atolia was closed. About 12 of the miners who have families at the property will be kept working at the property during November.

NEVADA COUNTY.

Good ore has been found at the mine of the Bear River Consolidated Tunnel Co., this vein is 6 ft. wide and the ore is a sulphide with some free gold. This company owns property on both sides of Bear river. The adit on the north bank is 256 ft. long. This company is composed mainly of local people.—The management of the Gold Mound property on Deadman's Flat intends to sink the shaft to a depth of 400 ft. At present the shaft is 165 ft. deep. Levels will be run at 200 ft. and 400 ft., but none at 300 ft. The vein in the Gold Mound mine has widened to 7 ft.; the walls of the vein are well defined. The ore carries some free gold.—The Belle Union M. Co. has started to drive a new adit to

develop the vein at greater depth. This adit should reach the lode within 200 ft. A winze will then be sunk on the vein.—The recent decision in the Pine Hill-Rosenthal litigation leads many to think that a compromise will be effected soon and that the Pine Hill mine will be working full force again by spring. The adit has been recently re-timbered and many improvements have been made this summer but, on account of the litigation, the new hoist which is at the mine has not been installed as yet. The ore at this mine is copper carrying gold and silver.

PLACER COUNTY.

At the meeting of the shareholders of the United Water & Power Co. of California, held in San Francisco Nov. 13, all shareholders being present, the following officers were elected: President, Arthur L. Pearse; vice-president, James L. Gould; secretary and treasurer, Chas. H. Town. These officers constitute the board of directors. The board of directors chose James D. Stewart general manager. It was also voted to issue 40,000 7% preferred non-cumulative shares. Nearly all these shares have been placed and the funds will be used in developing the company's mines near Gold Run in this county.

SHASTA COUNTY.

The Mammoth Copper Mining Co. is practically the mainstay of this county at present—at least as to mining; its monthly payroll amounts to about \$80,000. This com-

gauge steam railroad, then 3,000 ft. of gravity railway, which transfers to the steam-road below, the ore from the electric railway, two miles long, which carries the ore from the mine to the head of the gravity road. This construction has been necessitated owing to the inadequate capacity of the aerial tramway at present being used.

The electric smelter at Heroult is about ready to commence work; the output at first will be about 3 tons of ferro-silicon per day.—The second payment has been made by the Western Exploitation Co. on the Milkmaid mine, near French Gulch. The bond has 6 months longer to run. Twelve men are working at this mine. Edward Lewis is foreman. This company shipped 400 sacks of ore to the Selby smelter some time ago, and last week it shipped 400 sacks, and 300 sacks are at the depot ready for shipment. At present this company has to wait 30 days for payment from the smelter.

SIERRA COUNTY.

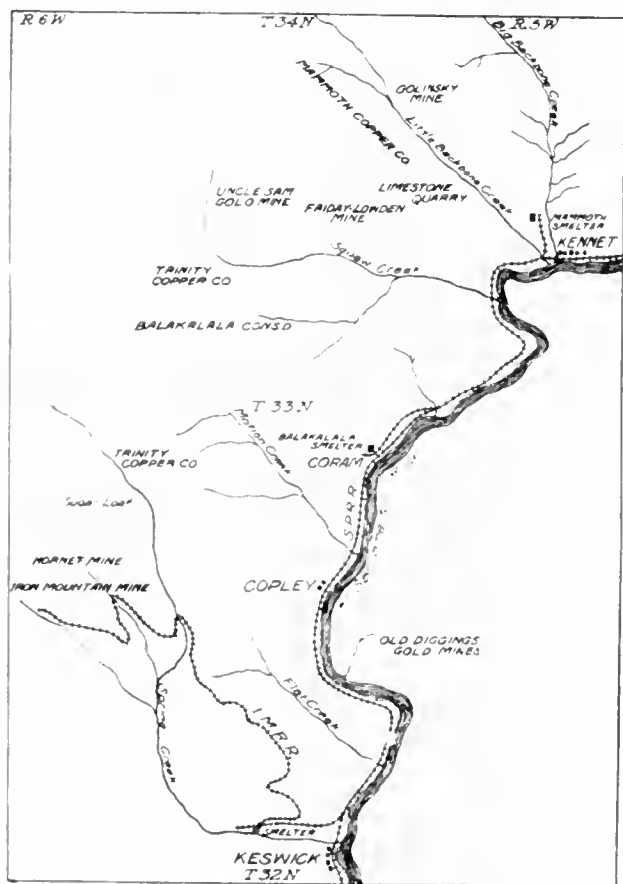

At the Telegraph drift mine an air-compressor is being installed to run the machine-drills in the shaft which is to be sunk to develop the quartz lode found in the property. The telephone line between the mine and Downieville is almost completed.—The 5-stamp mill at the Papoose mine in Jim Crow canyon is running at full capacity. Five more stamps are to be added shortly. The adit which is being driven to give greater depth on the vein is expected to cut the lode soon.—At the West Point drift mine, owned by Peckwith & Spaulding, near Monte Cristo, good pay-gravel is being mined. Much development work is being done so that many miners can be employed as soon as the winter rains begin.—The adit at the property of the Herkimer company is being driven ahead.—At the White Bear mine the raise, which is 267 ft. high, has cut into pipe-clay pitching into the mountain, indicating that the raise is too far west and is in the rim rock. A drift has been started from the raise at a point 60 ft. below where it cut the rim rock. It is hoped that this will be sufficiently deep to be below the channel. The Costa company owns 1½ miles along the supposed course of this ancient channel.—At the Wilson & Tyre mine, on Galloway hill, a dumping and washing house is being built.

W. H. Griffith of Denver has bought the Cleveland quartz mine near Sierra city; an 18-stamp mill is on this property. Work at the mine will soon be resumed.—The new mill at the Keystone mine is almost completed. Wm. and Fred Perryman, Thos. Botting, and Claus Hansen have taken a lease on the mine.—The motors and other electrical apparatus to drive the air-compressor at the Telegraph mine have arrived and will be installed immediately.

TRINITY COUNTY.

At the Union Hill mine, near Lewiston, 30 men are at work enlarging the tunnel, which is to take the tailing from this hydraulic mine to Trinity river, instead of letting them go into Weaver creek, as at present. It will take three or four months to complete this work.—The Trinity River M. Co. has laid off the night shift at the tunnel, which it is driving about 1½ miles above Lewiston. Five men are working on day shift. This tunnel, which will be 1,300 ft. long, is about half completed; it is being driven to divert Trinity river from its present channel.—Work will soon commence at the Red Hill hydraulic mine on Trinity river. Gerald O'Shea and Japhet Lindeberg have bought the water-rights from the Huertevant estate, and this water will be used in operating this hydraulic mine.—It is reported that Ed Paulsen and Jack Leas, who are leasing in the Brown Bear mine near Deadwood, have found rich ore in ground between the China and the Watt adits.

At the Mountain Boomer mine, in the New River district, a 16-in. streak of good ore has been found in the lower tunnel. Wm. Montgomery, who is working the mine under a bond and lease, has 15 men doing general development work. Some good ore has also been found in the upper levels. The mill will be started soon.—The Utica and Buckeye group of mines has been bonded to Goldfield people by Larcine, Brown, and Williams. Work will be done on all these claims this winter.—It is expected that the Quimby mine, which has been closed for some time

Map of the Copper Region of Shasta County, California.

pany is still doing much construction work. The new stack, which is to serve seven furnaces, is now 70 ft. high and is being built at the rate of 7 ft. per day; its height when completed will be 200 ft. The old stack will then be used for the two converter stands now being installed so that the Mammoth company can make blister-copper. All the concrete work is finished, the machinery has arrived, and much of it has been already installed. On the line of the new railroad from the mine to the smelter, the hoist at the head of the gravity railway is being installed; the roadbed for the electric railway is completed, half of the track-laying is finished, and the trolley wire has been put up. This new transportation line from the Mammoth smelter to the mine is quite unique. From the smelter to the bottom of the gravity railway is three miles of standard-

owing to dissensions among the stockholders, will soon resume.—James Musick is putting in hydraulic machinery to work the gravel which he recently discovered just below the mouth of Eagle creek.—Brackett & James have made ready their placer mine below the mouth of Virgin creek for the winter run.

TUOLUMNE COUNTY.

Work has been suspended at the Jumper mine, and all the employees except a watchman and two engineers have been laid off. The main shaft is now 1,900 ft. deep; as the hoisting engine cannot raise ore from a greater depth, deeper mining is impossible until a new hoist is provided. John Evans, Dan Newman, Richard O'Brien, and James Tucker have taken a lease on the West vein and have commenced work.—George Stayton has sold to James M. McCurry an undivided one-twelfth interest in the Mother Lode mine near Jacksonville. The Joy Mining Co. has been organized in Santa Barbara to develop this property.—The Imperial mill has been finished and will be started as soon as the transformers are installed.

Work is progressing rapidly upon the Kanaka mill. Developments at the mine are quite satisfactory. Samuel Harris is manager.—It is expected that the Nonpareil mill will be completed by Dec. 1.—A full force of miners is working at the Mack mine, belonging to the Big Casino M. Co., and the mill is being run full time.—A new change-house is being built at the Longfellow mine near Big Oak and a large boiler is being installed to heat the building and to furnish the miners with plenty of hot water.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—For the last four years the Capital M. & T. Co. has developed its property until now it has larger ore reserves than any other company in Clear Creek county. The adit, which is at present 4,700 ft. long, has cut 15 veins, some of which are quite wide. On the largest of these veins, the Etna, the west drift has been driven for a distance of 150 ft. and the ore is in places 10 to 16 ft. wide, while the east drift is also 150 ft. long, but the vein is only 3 to 6 ft. wide. A large force of men is blocking out the orebody and the ore from this work is run to plats at the portal of the adit while the 100-ton mill is being erected. The mill-building is about finished and the installing of machinery has begun. Hendrie & Bolthoff of Denver are erecting the mill. A new 25-drill Leyner compressor has been installed. Wm. M. Cooper is manager of the company.—The Linn Consolidated M. & M. Co. expects to have its new 50-ton concentrating mill finished by Dec. 1; the machinery is being installed by Frank Graham. The company is blocking out large reserves of lead-zinc ore in the Mineral Chief mine.—On the bottom level of the old workings of the Maud S. mine on Douglass Mtn. an 18-in. streak of rich silver ore has been found; this ore is along the hanging wall and had been missed by the earlier miners. Michael Kelly is working the mine under a bond and lease. The old adit is being cleaned out and will be driven ahead to cut the vein at a depth of 300 ft. below the present workings.—The Raymond adit is now 650 ft. long. According to surveys the Paris vein will be reached within 50 ft., at which time it is expected that important discoveries will be made. Two veins have been intersected and more or less mineral is showing, but comparatively little driving has been done. The Paris vein was cut by the Capital adit at a vertical depth of 1,900 ft., the orebody at that point being 3 to 3½ ft. wide; this vein carries gold, silver, and copper. Arrangements are now being perfected whereby the Raymond Tunnel Co. can prosecute operations through the Capital adit. Joseph Raymond of Georgetown is manager of this enterprise.—At a distance of 750 ft. from the portal of the Mohawk adit on Saxon Mtn. a body of ore has been exposed which is 18 in. wide and rich in lead and silver. Apparently the vein is the old Choctaw, whence a production of over \$100,000 was made a number of years ago from shaft-workings down to a depth of 150 ft. J. J. Cully of Georgetown is in charge at this mine.—Eighteen inches of good lead ore has been found at the Edinburgh mine on Republican Mtn. while running the

lower adit to cut the vein below the upper workings. This gives an increased depth of 145 ft. The property is being operated by Nulph & Leisy of Georgetown under bond and lease.—M. J. Riley, leasing on the Sunburst, Democrat Mtn., is stoping on a body of ore that measures from 3 to 3½ ft. in width. The stope is 95 ft. in length, having been carried for 85 ft. About 18 in. of the material is shipping ore, the rest is of good milling-grade.—Butts & Co., leasing on the 240-ft. level of the Astor mine has found two 4-in. streaks of very rich silver ore. This mine belongs to the Red Oak M. & M. Co.; A. B. Montgomery of Denver is general manager.—J. J. White, manager of the Prudential M. & T. Co., has awarded a contract for the driving of the Prudential tunnel an additional 100 ft. According to surveys this will take the heading past the Turner vein, which at surface is of good grade. This property is on Republican Mtn. on one of the richest mineral zones in the Georgetown district. If driven to its objective the Prudential adit will intersect the Pay Rock, Wisconsin, Corry City, and other mines at an increased depth of from 500 to 700 ft. under their present deepest workings. The tunnel is now in 850 ft.

Georgetown, Nov. 7.

TELLER COUNTY.

(Special Correspondence).—Work is progressing rapidly on the Independence mill in which the ore from the dump of the Independence mine will be treated; this will have a capacity of 400 tons per day. It is estimated that this dump will keep the mill in ore for 10 years. The ore will be concentrated on Card tables and then cyanided. Philip Argall of Denver is the consulting engineer, H. E. Nelson construction engineer, and A. R. Minner superintendent of construction.—F. M. Kurrie, superintendent of the Portland mine, is opening up two new levels in Portland ground, one at 1,200 ft. and the other at 1,500 ft.; these are being developed from the No. 2 shaft. As this work interferes with the hoisting, they are not trying to produce full capacity. Work on the 1,500-ft. level has not as yet reached the ore, but the ore has been found on the 1,200-ft. level. A new 30-drill Ingersoll compressor has recently been installed; this is operated by a 300-hp. motor.

Victor, Nov. 8.

(Special Correspondence).—The Trilby Mines Co., for which James T. Stewart is manager, is building a 60-ton mill at its mine. This plant will be arranged so that it can be increased to a capacity of 150 tons per day. An Abbe tube-mill is to be used for fine grinding. Cyanidation will be used. The Gold Sovereign is getting ready to ship 2,500 tons per month to the Golden Cycle mill when that mill is ready to receive ore; this, it is understood, will be about a month from now.—Eaton & Blanchard, who are operating the Goodwill mine under lease, are taking out some ore; they are also working the Bonanza King through the same adit. A new roaster will shortly be installed in the W. P. H. Leasing Co.'s mill. Some changes are being made in the mill which were found necessary after it had been operated a short time. The Isabella mill is handling an average of 125 tons per day of ore which averages about \$4.50 per ton; the extraction is about 80%. Practically all this ore comes from the dump. They expect to install two more leaching-tanks. Geo. D. Kilbourne is manager and A. N. Finn superintendent of the mill.—The Wild Horse mill is under lease to Thos. Kavanaugh; he is treating custom ore in this mill as well as ore from the mine. Last month he treated 700 tons of ore, but he expects to handle more in the future. At this mill the ore is crushed and then treated with cyanide.—The Blue Flag G. M. Co.'s mill has a capacity of 50 tons per day. The ore is crushed wet; the sand and fine are separated in Callow tanks; Butters distributors are used to feed the sand to the cyanide vats while the slime is agitated in specially designed vats having a conical bottom. S. C. Paxton is superintendent, W. H. Jenkins consulting engineer, J. F. Erisman general manager. It is claimed that a good extraction is made at this mill without roasting the ore. This mill is run by electric power.

Cripple Creek, Nov. 8.

MICHIGAN.

KEWEENAW COUNTY.

The Calumet & Hecla, the Wolverine, and the Mohawk mining companies posted notices October 31 announcing a reduction of wages. The Mohawk and the Wolverine reduction is 5% of the present wages, bringing them to the same schedule as before January 1 of this year, when a raise of 5% in wages was granted. This reduction goes into effect November 1. The Calumet & Hecla reduction amounts to 12½% and goes into effect December 1. It also applies to workings on the Osceola and the Kearsarge lodes. As yet none of the other companies have made a reduction, but it is expected that they will.—At the Keweenaw Copper Co. No. 1 shaft the vein in the lower levels is being developed with satisfactory results. This shaft is now 900 ft. deep, and it is expected that by January 1 this shaft will be 1,000 ft. deep. At 825 ft. the station for the 9th level is being cut. In the deeper levels there is less calcite in the vein, and apparently the copper content of the ore is increasing. Eleven drills are being used at this mine. On the 7th level, 675 ft. deep on the incline, a cross-cut is being driven to develop the Allouez conglomerate; this cross-cut is at present 100 ft. long and is expected to cut the conglomerate in the next 125 ft. In this cross-cut about 15 ft. west of the Medora vein a similar vein was cut and some development has been done on this new vein. Another cross-cut to the east of the shaft has been started to intercept this new lode.—About 300 men are working on the Keweenaw Central extension, which is to connect Mohawk and Calumet. This railroad passes near many of the large mines—the Ahmeek, Allouez, Kearsarge, and Centennial. It is expected that the line will be in operation by January 1.—The new sand-conveying system installed at the Mohawk mill is working quite satisfactorily.—It is announced that the Canadian S. & R. Co. will commence work on its smelter at Sault Ste. Marie on the Canadian side December 1. This smelter is to treat copper, nickel, and cobalt ores and will have a capacity of 150 tons per day. Otto Stahlmann, formerly connected with the Calumet & Hecla Co. and the Anaconda Copper Co., is manager. He formerly worked for the Cobalt Smelting Co. of Saxony, Germany, where he acquired experience in smelting ores quite similar to those from Cobalt, Ontario. This smelter will draw from Cobalt and Sudbury mainly for its supply of ore.

NEVADA.

ESMERALDA COUNTY.

The output of the Goldfield district for the week ending Nov. 8 was 1,950 tons of ore having an estimated value of \$204,850. This diminution of output was caused by the fact that many companies have decided to store the ore on their dumps or to leave it in the stopes rather than wait upon the smelters to settle for the ore 45 days after it is received at the smelter. The Nevada Reduction Works refuses to receive more ore, so all the ore not shipped directly to the smelter was shipped through the Western Ore Purchasing Co. The Mohawk Jumbo is still shut down, pending the settlement of the boundary dispute, the Little Florence is not shipping any ore although mining at the rate of 100 tons per day, while the Mohawk is shipping a very small amount. The itemized shipments for the week are as follows: Mohawk mine, 125 tons; Red Top, 50; Mohawk Combination, 650; Florence L. & M. Co., 52; Rogers-Goldfield Syndicate, 112; Florence Annex, 64; Begole lease, 104; Nevadan, 26; Black Butte, 25; Goldfield Daisy, 47. The Combination mill treated 550 tons of ore from the Combination mine; the Kinkead mill 140 from the Red Top.—The shipment this week is the first from the Florence Annex lease, the ore being quite high-grade.—The Little Florence is piling up all its ore at the mine; most of the ore is coming from the 400-ft. level. The cross-cut on the 500 is in 30 ft. and will soon cut the vein. The ore-bins at the mine are filled to overflowing and the ore is being piled on the ground. Owing to the large amount of money in its treasury the Little Florence has been able to keep mining at full capacity without shipping any ore. It is estimated that there is \$250,000 worth of ore on the dump at present.—The Florence Annex, on the

north end of the Firelight claim of the Florence, is now attracting much attention, as a 2-ft. vein of ore, reputed to assay \$800 per ton, has been found in it. This was found Oct. 17 in the west cross-cut of the 300-ft. level, 250 ft. from the shaft. The vein runs 20 deg. west of north; 35 ft. of driving has been done on it already. This lease has five more months to run and a large production is expected from it.—At the Codd lease on the St. Ives the shaft is being sunk at the rate of 3 ft. per day. A drift is being driven to the east on the 10 -ft. level to strike the ore-shoot recently struck on the St. Ives.—The Mohawk Combination lease has only three weeks more to run, so work is being pushed at this lease. The output from this lease is about 200 tons per day, while the Begole lease, a half interest in which is owned by the Mohawk Combination, produces 100 tons per day.—At the Florence L. & M. Co. much development work is being done. The drift on the 500-ft. level is being driven ahead rapidly, and it is thought that within 25 ft.

Map of the New Mining Districts of Nevada and California.

the vein that was cut in the upper levels will be intercepted. The shaft will then be sunk another 100 ft. Some stoping is being done on the 285-ft. level.—At the Daisy mine, near Diamondfield, another rich streak of ore has been found on the 210-ft. level. The company is now working three different orebodies on that level. The Truett shaft, now the main shaft, is being sunk, and in ten days it will have reached a depth of 400 ft., at which depth a station will be cut.—At the meeting of the stockholders of the Nevada Consolidated, Nov. 11, the following board of directors was elected: G. S. Nixon, George Wingfield, J. H. Mackenzie, J. W. Fenwick, J. S. Cook, J. D. Hubbard, and J. R. Davis.—A week ago last Wednesday 20 stamps of the 200-stamp mill at Blair, near Silver Peak, were started. By December 100 of the stamps and all the cyanide tanks will be running. About 200 men are working at the mine and mill. The ore is said to carry \$20 per ton. The plant is run by electric power furnished by the Nevada-California Power Co.

John W. Brock failed to be re-elected president of the Tonopah Mining Co., and instead James S. Austin was elected president and C. K. Lord vice-president. C. K. Lord, formerly vice-president of the Baltimore & Ohio, has been elected president of the Tonopah & Goldfield Railroad Co., R. H. Rushton and J. S. Austin vice-presidents.—During the summer many improvements have been made at the Desert mill at Millers. Additional pumping facility

and more boilers were installed, so that more slime can be handled; within 10 days 5 Woodbury concentrators will be added to the table capacity; 9 Johnson tables are expected to arrive at any time. Oil is now used to heat the boilers, as it is cheaper than coal. The oil supply now on hand is 180,000 gal.; the company also has 3,000 tons of coal in reserve, consequently no shortage of fuel is expected this winter. Last Tuesday a clean-up was made at the Desert and the Belmont mills, but its amount was not given out. The shipments from the Tonopah Mining Co. and from the Belmont Co. to the smelters approximate 200 to 300 tons per day.—At the California mine the ore-shoot, found on the 600-ft. level, has also been cut on the 720-ft. level; a raise from the 720-ft. level is now being driven in this ore. An ore-shoot pitching to the north has also been found on the 600-ft. level.

At the meeting of the shareholders of the Tonopah Belmont Development Co., held in New York Nov. 13, Richard G. Park was elected president to succeed John W. Brock.

NEW MEXICO.

GRANT COUNTY.

(Special Correspondence).—The Leopold Copper Co. has stopped development work at its mines in the Tyrone district, but its concentrator is still in operation. It has a considerable quantity of high-grade ore on hand.—The Comanche M. Co. has purchased the Iron Hill mines near Chloride Flat. The ore will be shipped to the smelter at Silver City and will supply the iron and lime needed as a flux. It is stated that the silver value of the ore is sufficient to pay the cost of smelting.—The Chemung M. Co. has shut down its mines at Copper Flat, in the Santa Rosa district, on account of the drop in the price of copper.—The striking of a rich vein of silver in the old Camp Fleming silver district by Baylor Polk has caused a revival of prospecting in that vicinity. Camp Fleming was a big producer of rich silver ore in the early '80s.—The smelter at the Comanche M. Co. has closed down so that another furnace can be installed and other repairs made. The smelter has been in constant operation for about a year.—The Burro Mountain Copper Co. has closed down its mines in the Burro district on account of the low price of copper.

Silver City, Nov. 8.

OREGON.

BAKER COUNTY.

(Special Correspondence).—At the Golden Star excellent ore is being developed, and the veins are improving with depth. Samples of the ore have been tested with encouraging results.—Rich ore containing much free gold has been discovered in the lower levels of the Morning mine. The strike was made in a cross-cut, and a raise is being driven to develop the ore. The mine is developed by 1,500 ft. of shafts, raises, and cross-cuts.—The United Elkhorn, Intermountain, and Red Dog mines are shipping ore. All the properties are looking well.—The Oregon Smelting & Refining Co. has completed arrangements with several companies in this section to insure a large and constant ore supply for the smelter. The coke problem is a source of anxiety to the smelter people, but it is thought that a supply can be obtained from Colorado.—The Ben Harrison, Independence, and adjoining properties were recently examined and sampled by Walter S. Keith, manager of the Oregon Smelting & Refining Co.—The Oregon Chief mine has been bonded by Ringold and associates, and will be developed on a large scale.—Extensive developments are under way at the Bi-metallic, which was recently purchased by a Cincinnati company.—A large number of Eastern mining men were recently examining mining properties in this district with a view to their purchase.

Baker City, Nov. 7.

(Special Correspondence).—John E. Searles of New York, president of the Cornucopia mines at Cornucopia, is visiting the property with the view of making many important alterations in the company's mill.—Manager Keith of the Sumpter smelter has completed contracts with the Elkhorn Mines Co. and the Columbia G. M. Co., and sufficient ore will come from these mines to keep the smelter continuously in blast after New Year.—Harris &

Boggs have completed arrangements whereby they will continue shipments all winter from the Peacock mine in the Seven Devils district of Idaho to the Sumpter smelter.—John A. Ringold and associates of Cincinnati have purchased the Bi-metallic mine in the Greenhorn Mtn. from Larsen & Richardson.—The Standard Consolidated Mines Co. are installing new machinery at their Standard mine and mill.—On November 1 the Columbia G. M. Co. will have their full battery of 20 stamps in operation.—W. B. Gladding of New York, president of the Sovereign Copper Co., is visiting the company's property on Goose creek.

Baker City, Nov. 9.

The Morning mine in the Greenhorn district is looking well.—The shaft at the Spero mine is now 100 ft. deep, but it is being sunk another 100 ft. On the 100-ft. level 130 ft. of driving has been done; the vein is 4 ft. wide on that level. There is about 40 tons of ore on the dump which has come from the development work done on the 100-ft. level.—Work has begun on the Daines 20-stamp mill.—Andy Larson and S. C. Richardson have found some good ore on their Skyline claim in a lode parallel to the Bi-metallic vein. The clean-up at the Pyx mill was quite encouraging; the mine will run all winter.

BRITISH COLUMBIA.

The ore output of British Columbia for last week was as follows: Boundary district shipped 30,701 tons; Rossland, 6,197; East of Columbia river, 3,699; total, 40,597 tons.

BOUNDARY DISTRICT.

Eight furnaces have been in operation at the Granby smelter this week and two at the British Columbia Copper Co.'s smelter. For the past five weeks the Granby mines have produced an average of 3,000 tons of ore per day. Last week 50 men were laid off at the Granby mines but, as most of these were on development, the output will be maintained. Diamond-drilling has been stopped at these mines for the winter.—About 70 men have been working at the Emma mine until last week when about half of the miners were laid off.—At the Fremont mine the main incline shaft is 150 ft. deep. When a depth of 200 ft. is attained, driving will be done on the lode both to the north and to the south. On the 85-ft. level good ore has been found in the drift which is 25 ft. long.—The pumps are still running at the Brooklyn mine, belonging to the Dominion Copper Co.—About 50 men have been laid off at the Mother Lode mine but the usual tonnage is being shipped daily.—A new crushing plant, similar to that at the Granby mines, will be installed at the British Columbia Copper Co.'s smelter at Greenwood. The jaw-crusher will be large enough to take a boulder 24 by 36 in. and will be run by a 100-hp. motor.—The Snowshoe mine shipped 6,560 tons this week; the Mother Lode, 3,440; the Napoleon, 93; the Granby mines, 20,000 tons.

CARIBOO DISTRICT.

The Sloean-Cariboo M. & D. Co. has received a new Northey pump having a capacity of 325 gal. per minute. This has been installed at its property on Canadian creek and sinking has been resumed.—The damage to the Bear Hydraulic M. Co. property, due to the breaking of the dam early last summer, has been repaired.

ROSSLAND DISTRICT.

The output of the Rossland district for last week was as follows: Centre Star, 3,203 tons; Le Roi, 1,925; Le Roi No. 2, 560; White Bear, 105.—H. H. Claudet is installing a 40-ton mill, using the Elmore vacuum-oil process, at the Giant mine, near Golden. This mill will probably be in operation within two months. The ore carries lead with a small amount of silver.

MEXICO.

CHIHUAHUA.

The Greene Gold-Silver Co. has reduced the wages at its properties 25%. White miners will get \$3 gold instead of \$4, while Mexican miners will get \$1.75 instead of \$2.50. A large number of men will also be laid off. The present mill at Concheno has a capacity of 175 tons per day. The new mill, which is being built, will have a capacity of 500 tons. All the ore will be slimed and a new system of agitation will be used in it.

Special Correspondence.

Mexico City.

Improvements Under Way at Cananea.—Large Furnaces.—Greene-Cananea Mines.—The Democrata.—La Dicha Affairs.—Gloomy Condition of Affairs in Northern Mexico.

Now that there is such a real dearth of important mining news throughout the Republic of Mexico it would seem quite an appropriate time to touch upon some of the new work that was either in course of construction or contemplated when the financial troubles arose in New York and put a check on practically all plans of any great consequence. Most important and on the largest scale of perhaps any other work, was that instituted by L. D. Ricketts on the Greene-Cananea, and for which it was said \$4,000,000 was placed in the treasury. The saving system, more or less after methods used in the Lake Superior copper mines, had been introduced, very materially reducing the cost of mining, and the alterations at the metallurgical end were to give far more economy there and reduce the cost of production of copper from 11 to 13 cents, which it had been costing, down to about 9 or 10 cents per pound. These alterations consisted mainly in increasing the size of the furnaces, so that the plant would be able to treat daily 10,000 tons, instead of 3,000 tons of material, and the enlargement of the concentrating plant from 2,400 tons to 10,000 tons daily, in 1,000 ton units. Of the changes in the smelting plant, four of the eight furnaces had been rebuilt and in commission, and two others were nearing completion, while plans had been prepared for three more furnaces in addition to the eight. Toward the alterations on the concentrating plant little had been done, as it was deemed wiser to rush the furnaces to completion to handle the increased output of mines and concentrator; but now all is in abeyance. The Democrata Mining Co., nearby, which was showing up wonderfully well with large bodies of ore, and had completed the foundations of its new 250-ton stack, built on the same lines as the Calumet & Arizona furnaces at Douglas, Arizona, but a foot longer, and expected to blow in this month, is letting things stand as they were and shipping what little ore is being produced; that which was being handled at the Greene-Cananea plant, is now going to El Paso. The survey for the railroad of the Belen Copper Co., from Carbo to Camp Copete, and which was to give an outlet to a number of large companies such as the Belen, Giroux Consolidated, and the Copete, had been completed and the survey and plans approved by the Mexican Government, but now nothing is heard concerning it. The New York meeting of the stockholders of La Dicha Mining & Smelting Co., acting on the request of a former meeting in Mexico City, had deposed George Mitchell and elected F. A. I. Cassidy, of Fort Glenn, Md., as president in his stead, with Thomas E. Wing as general manager, who were at once most keen on pushing to early completion the 80 miles of railroad from La Dicha to San Marquez, known as La Dicha & Pacific Railroad, and by this outlet to the Pacific place the mines and smelter on a paying basis. But now the silence is oppressive. W. C. Greene who, after selling out the greater part of his holdings in Cananea, moved his basis of operation to the State of Chihuahua and obtained concessions for the erection of several reduc-

tion plants and power plants in that State, and was contemplating the reopening of the old Federal smelter at El Paso, is now spoken of as being close to a receivership and chasing for money to meet his payrolls. In my previous letters in the PRESS I have spoken of the cutting off of work on the Guanajuato Belt Line Railroad and the closing of various mines throughout the country, and it is feared that the end is not yet.

Another correspondent writes: The effects of the sudden drop in the copper market are nowhere more noticeable than in northern Sonora, where the great properties of the Greene-Cananea are now in a state of suspended animation. Only four furnaces out of seven remain in operation and mining is practically at an end. All day long and all night long wagon-trains, burros-trains, and people on foot are pouring down the 60 miles of highway from Cananea to Imuris and thence southward through the Magdalena valley, penniless with the improvidence of Mexican miners and not knowing how they may feed themselves on their long journey to distant homes. The *rurales* or State militia patrol the roads to prevent disorder. Many American workmen are be-

Mexico.

ing retained at reduced wages, but thousands of Mexicans have been discharged. It is reported that early in November the whole camp will be closed down. In contrast, the Phelps-Dodge company is still going on with the work at Nacozari.

The Mexican Central is now running trains to Guanajuato. The slime plant in the Pinguico mill is completed and Carlos Van Law has started a Butters filter-plant at the Bustos mill.

Butte, Montana.

Butte Coalition.—Cessation of Production.—Work of Development.—

A Strike in the Parrot.—North Butte Extension.—Butte & Bacorn.

The Butte Coalition Co. has stopped all work at its mines except development work in the Rarus, where about 175 men are still employed. The only ore mined now is that which is taken out in the course of development. Work is going on at 10 different places in the mine and from four of them ore is mined, averaging about 50 tons per day. When the curtailment order went into effect several months ago the Coalition Co. was mining 1,600 tons per day. The company now argues that it can better use its time and treasury in opening its orebodies and blocking them out preparatory to a big output when the demand for copper is again normal. The Rarus shaft is being sunk and that work is to con-

tinue indefinitely. The shaft is now 2,000 ft. deep. The lowest level is at that point and is known as the 17th level, from which the south vein has been cross-cut, but no driving on it has yet been done there. On the 16th level the south vein has been cross-cut and a drift about 100 ft. has been driven on it, opening a splendid orebody, larger and of higher grade than any on the upper levels. The company is also cross-cutting for the north veins and is driving into the Minnie Healey for the purpose of opening that property at greater depth. The Minnie Healey will eventually be mined through the Rarus and Tramway shafts. The new Tramway shaft has reached the 1,100-ft. level, from which a raise has been made for several hundred feet, but the shaft has not been enlarged and timbered all the way. In a month or six weeks the shaft will be completed and timbered to the 1,100-ft. level, when sinking will be resumed. The big steel head-frame at the Tramway is going up. The work had been delayed by a controversy between labor-unions as to whether the ropemen or the structural iron workers should do the work. The ropemen won and are making a record in putting up the frame. The iron workers put up a similar frame for the Boston & Montana at the Leonard mine and it took them 60 days. The ropemen promise to complete the Tramway shaft in 30 days. The Coalition is opening great bodies of ore in the Rarus and Minnie Healey and when the demand for copper becomes normal again the company will be able to maintain a steady output.

Under the management and direction of Arthur C. Carson, general manager, and George Moulthrop, superintendent, the Coalition properties have been tremendously improved, and it is predicted that in a few years they will be among the most important in the Butte district. Nothing is being done in the Corra or Nipper mines at present, though a short time ago some good ore was mined from the Nipper through the Parrot mine.

It has been persistently reported among the miners that the Parrot has made a strike recently, but Manager Gallwey denies it. The Parrot Co. is pushing development and has just completed sinking its main shaft, which is now 2,030 ft. deep. Cross-cuts have been started from the 1,900 and 2,000-ft. stations to intercept the veins south of the shaft. The company has reduced its output to about 150 tons of ore per day, which comes from the 1,600, 1,700, and 1,800-ft. levels, where some development work is also going on. The Parrot Co. is also working the Little Mina, but that property is yielding only a small amount of ore, which is mined on the 800 and 1,800-ft. levels. The Little Mina shaft is 1,000 ft. deep.—The North Butte Extension Co. has completed a station at the 300 and work on the cross-cut has started. The station is 15 ft. square and is big enough to accommodate a large pump. The vein is not far from the shaft, and it was uncovered at the surface while a foundation was being made for the engine-house. Several vein stringers were cut by the shaft. The water coming from the shaft is also highly impregnated with copper. John A. Ryan, the superintendent, expects that the vein will be reached within 60 ft. of the shaft, and that it will be found to carry commercial ore. A second boiler was recently added to the plant and the company is now equipped for sinking to a depth of 1,200 feet.

The Butte & Bacorn Co. has retained a small force of men at the mines and is still working on the two drifts on the veins opened at the 1,000-ft. level. While no commercial ore has yet been found, the improvement continues and Fred Bacorn, the manager, is still confident that ore will be found at the present depth.—Work had been resumed at Clark's West Stewart mine, which had been suspended for several weeks while a new steel dumping

equipment was being installed.—The Butte Central and Boston lessees are paying good royalties again and the company is more than making expenses from that income.

Johannesburg, Transvaal.

September Output.—Effects of Poor Labor.—Details of Production.—Increased Stamp-duty.—Future of the Industry.—Lead Mining.—The Cyferbull Diggings.

On the whole, the output of gold for September can be considered satisfactory. September was a 30-day month, one working day less than August, and there were nearly 3,000 time-expired coolies sent back to China, so that a new record output was impossible. The output for the Transvaal amounted to 538,034 oz., valued at £2,285,424, of which the Rand contributed 517,746 oz., valued at £2,199,247. One or two of the Chinese mines have been hard hit by the loss of their coolies, who are now highly skilled mine-workers. In the place of the Chinamen raw Kaffirs have been taken on, many of whom have never seen a mine before. Several months will elapse before these Kaffirs are efficient, and the mines that have lost the coolies will show decreased profits unless some rich stopes can be drawn from. One mine that has been earning about £18,000 profit per month showed a drop of nearly £5,000 for September, while another Chinese mine that lost its coolies last month fell from £10,000 profit to £2,000. These figures show what a serious thing it is to try to run a mine with raw labor. For a few months managers of Chinese mines are going to have great difficulty in keeping their average profits. Working costs are bound to go up on these mines, for until the Kaffir is trained to his work he accomplishes very little. The most tantalizing thing of all is that the Kaffirs leave soon after they are broken in and you start afresh with a new crowd.

The Robinson gold mine is again the leader as a producer, the amount of gold turned out by this company for September being 25,415 oz. Second on the list is the Simmer & Jack with 24,577 oz., while the Robinson Deep is third with an output of 19,859 oz. It is interesting to note how the duty per stamp has increased of late, owing to the introduction of tube-mills. During September there were six mills on the Rand showing a stamping duty of seven tons and over per stamp per 24 hours. On the Luipaard's Vlei Estate the exceedingly high duty of 8.7 tons per day was reached. As regards sorting, the mines show considerable variation, from 37% in the case of the Princess Estate mine to no sorting in the case of the Consolidated Langlaagte mine.

During the month some important evidence has been given before the Government commissions. The witnesses, who speak with authority, such as consulting engineers and mine managers, are not over optimistic on the future of the mines of the Rand, and it is generally agreed that unless costs can be brought down to somewhere between 16 and 17 shillings the margin of profit in 10 years will have gone to the vanishing point. If the policy of the Dutch Government is carried out the chances of any great reduction in working costs are small, and as the Het Volk party are in for an indefinite period, perhaps until the end of time, it is no wonder that mining men view the future with grave apprehension.

The monthly report of the Edendale Estates shows that good progress is being made on this lead proposition. Besides a fair amount of development work during September, 214 tons of concentrate containing 80% lead and 60 tons of zinc blende containing approximately 45% spelter were shipped. After this month it is hoped to have the furnace working satisfactorily and to be in a position to supply the local market. There is a consider-

able demand for pig lead on the Rand, especially in connection with the Tavener process.

The men at work on the Cyferbult alluvial gold diggings, in the Krugersdorp district, do not seem to be meeting with any great success. They have much to contend against. Their Kaffirs have become expert thieves, and according to one old prospector the natives get away with a good deal of gold. The dry crushers which were sent to the diggings have proved a failure and the men prefer to pay the very high price asked for water. Unfortunately, also, there has been a great deal of the ground locked up, and until the present gold law is amended little can be done with the claims held under license. There are several small veins in the district and a few small batteries, from 5 to 10 stamps, are at work. The gold occurrence is erratic, however, and the position of the owners is somewhat hazardous. One or two of these men have made a bad mistake in starting to crush before they had opened up sufficient tonnage, and one man is now forced to close down, after a run of a month or so, in order to develop. The prospects of the Cyferbult district are not promising. A few men seem to be making a living, but not much more.

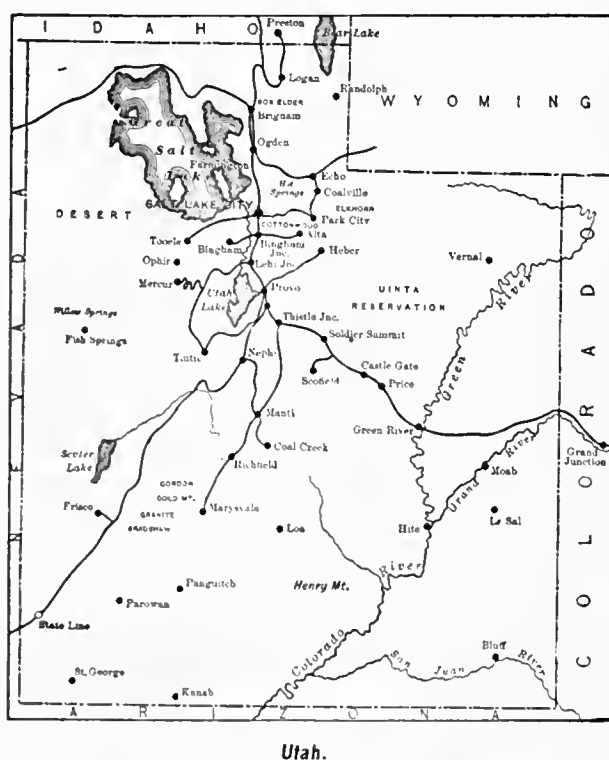

Salt Lake, Utah.

Smoke Suit Decision.—Probable Effect.—Reduction in Wages.—Strike Settled at Park City.—Ontario Adit Repaired.—Bingham Smelter Closes.—Shipments From Tintic.—Litigation Ends.

The United States Court of Appeals at St. Paul has affirmed the judgment of the United States District Court of Utah in the smelter smoke cases. The effect of this decision, unless modified in some form, will be the closing of some of the existing plants, particularly those to which copper ores are sent for treatment. The injunction is made permanent against the Utah Consolidated, the Bingham Consolidated Mining & Smelting, and the United States Smelting, Refining & Mining companies. The American Smelting & Refining Co., while it was a defendant in the cases when tried, will not be affected by the decree for the reason that a compromise agreement or stipulation has been entered into between the smelting company and the farmers who were plaintiffs in the cases tried. By the payment of a large sum of money and the installation of bag-houses and other mechanical appliances for the arrest of the sulphur dioxide in the fume, the Court was asked for a modified decree permitting the American company to continue its smelting operations at what is known as the Murray plant, which treats lead-silver ores. The copper smelter at Garfield, operated under the management of the American Smelting & Refining Co., has never entered into the controversy, it having been built at a point where little or no damage can be done to growing vegetation or live-stock. Inasmuch as the Bingham Consolidated Mining & Smelting Co. has practically ceased the treatment of ore at Bingham Junction and is soon to abandon its smelter entirely, the only concerns left to bear the burden of the Court's decree are the Utah Consolidated and the United States companies. The Utah Consolidated has selected another site and is preparing to build a smelter thereon, probably next year; but the United States company has taken no definite steps in that direction; the management contending that it is not a physical impossibility to control the situation to the extent of doing no damage to the surrounding country. It is believed that the case will be carried to the Supreme Court of the United States and that in the meantime the smelting companies will be permitted to continue the operation of their plants under an indemnity bond. In his decree, Judge John Marshall, of the Utah Court, enjoined the defendant smelt-

ing companies from smelting ores containing an excess of 10% sulphur in the charge or sending out in the atmosphere any fume containing arsenic.

The operators of Park City have agreed on a uniform wage-scale for that camp; it becomes operative on November 15 and amounts to a reduction of from 25 to 50c. per day as compared to the schedule in effect during the past year. Engineers are to receive \$4; timbermen, \$3.50; machine-men, \$3.25; station-tenders, \$3.50; all underground men, \$3; carpenters, \$4; carpenter's helpers, \$3; blacksmiths, \$4; blacksmith's helpers, \$3; tool-sharpeners, \$3.50; motormen, \$3.25; firemen, \$3; millmen, carpenters and construction, \$4; repair-men, \$3.50; repair-men's helpers, \$3; millmen, \$3; laborers and outside men, \$2.75. This scale does not apply to boys under 21 years of age, who may be employed underground at the rate of \$2.50, or outside at \$2 per shift.—The Miners'

Union has called off the strike which was declared against the Daly West, Ontario, Daly, and Little Bell mines about two months ago. The men struck because the management of the Daly West discharged a shift-boss who belonged to the union. The miners' organization not only demanded his reinstatement, but also demanded union recognition, which was denied. The mines were closed pending the strike; but preparations are being made to resume operations.—The Ontario drainage adit at Park City is about to be restored to its former usefulness after having been closed for more than two years on account of caves. The main channel has been tapped from a drift around what is believed to be the last of the caves between shafts No. 2 and 3 by means of a 3½-in. diamond-drill hole. Other holes are being drilled, through which it is expected the mine will become drained. The task of unwatering has been a most difficult one and decidedly expensive. The restoration of the adit will enable the resumption of work on the lower levels of the principal mines of the district which have been flooded since the adit was damaged.

The orders to stop work at the Bingham Consolidated smelter has caused a shut-down of the Grand Central mine at Tintic. The mining company had a contract with the smelting company through which the latter obligated itself to purchase the entire output of the mine,

and now that the contract has been abrogated through the shut-down at the smelter, the Grand Central is left without a market for the time being. It is only in exceptional cases that the smelters still active are accepting ore for treatment that they have not already contracted for—the ban being placed particularly upon silicious ores. The closing of the Grand Central is the first serious shut-down reported from Tintic. Several properties there have curtailed their output, but with this one exception there has been no complete shut-down. Ore shipments from Tintic last week amounted to 109 carloads; the contributing mines and amounts being: Ajax, 2; Beck Tunnel, 6; Bullion Beck, 5; Colorado, 9; Centennial Eureka, 42; Eureka Hill, 2; Eagle & Blue Bell, 1; Grand Central, 4; Lower Mammoth, 5; Mammoth, 2; Scranton, 6; Tintic Iron, 11; Uncle Sam, 5; May Day, 5; Victoria, 2; Yankee Con., 2 carloads.

The seven years of expensive litigation between the Grand Central and Mammoth Mining companies, both operating in the Tintic district, has ended in a victory for the Grand Central, which has been awarded a verdict of \$91,349, which with interest at 8% per annum (\$58,463), made an aggregate total of \$149,812. The Grand Central brought suit in the first place for \$500,000, the alleged valuation of ore extracted from the Silveropolis claim, but which the Mammoth company contended it owned by reason of extra-lateral rights. Coincident with the decision rendered against it and in favor of the Grand Central, the Mammoth Mining Co. marketed a carload of ore that brought over \$100,000. The lot consisted of 53 tons, 18 of which averaged 145 oz. gold per ton; 13 tons went better than 21 oz. in gold. The company will sink the working shaft to 2,500 feet.

The shaft at the Apex mine, one of the Tintic possessions of F. Augustus Heinze and associates, is down 1,150 ft. The ore being developed there is similar in character to that in the Eagle & Blue Bell mine.

Three Utah mining companies posted dividends last week. The Mammoth, \$20,000; May Day, \$22,000; and Uncle Sam Consolidated, \$15,000.

Wallace, Idaho.

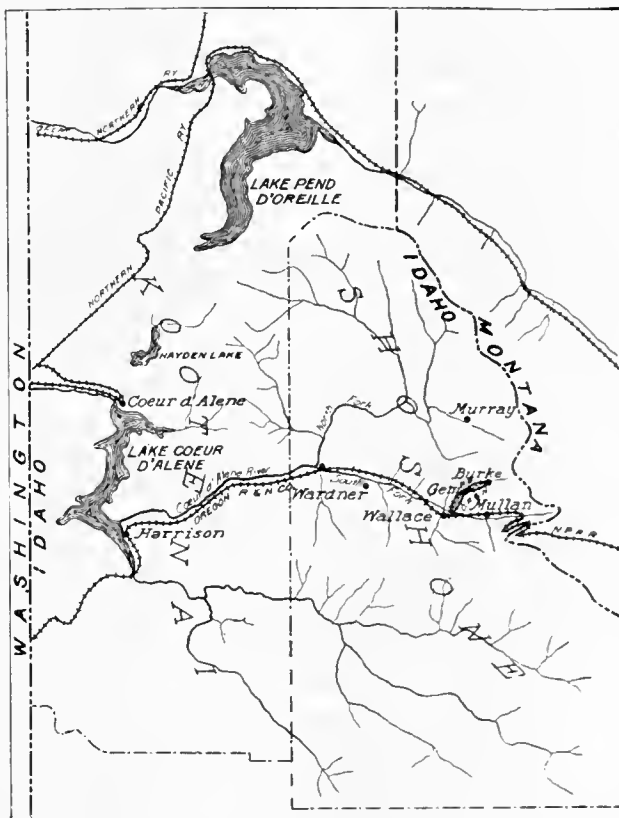

Mines of the Coeur d'Alene.—Effects of the Financial Stringency.—The Surprise Mill Stops Work.—Bunker Hill Dividends.—Native Copper in Slate.—The Lookout District.—National Mine.—Missoula Copper Company.

The depression in both the financial and metal markets have not been without effect on this district, but at the same time mining activity is greater than ever before in the history of the country. One or two of the larger companies have closed their mills and reduced the size of their dividends; but most of the smaller companies are active, and there are more prospects under development than ever before. New strikes are being reported almost daily, and everything is looking prosperous.—The mill of the Surprise mine at Wardner has just been closed owing to the refusal of the smelters to handle the ore, and about 40 men have been thrown out of work. The mill had only been completed about a month, but it is promised that a market will be found for the ore by the beginning of the year. The development of the property will continue in spite of the shut-down, and additional machinery is being installed at a cost of about \$40,000.

The Bunker Hill & Sullivan Mining & Concentrating Co. has paid its 123rd dividend, amounting to \$120,000. This makes the dividends paid since January 1, \$1,860,000, and the grand total paid by the mine, \$9,726,000.—An assessment of two mills per share has been declared on the capital stock of the Echo Mining Co., the property of which adjoins the Oom Paul and Moonlight

mines at Burke. The mine looks promising; four feet of blue talc and quartz, carrying silver, was recently encountered in the west drift about 1,200 ft. from the portal of the tunnel. Work on this strike is being pushed as rapidly as possible.—An important strike of native copper embedded in slate has just been made in the Hypotheek mine at Kingston; assays show from 4½ to 5% copper. The ore was encountered on the 180-ft. level and at a depth of about 475 ft. The lode is about 40 ft. wide, the native copper ore being about 5 ft. wide. This is the only mine in the Coeur d'Alene where native copper has been encountered in quantity.

Some splendid ore is being encountered in the Lookout district and great activity prevails. The Copper Head

The Coeur d'Alene, Idaho.

Mining Co. has just broken into the lode at a depth of about 167 ft. The lode is about 7 ft. wide and contains a pay-streak of from 6 to 8 in. wide, samples of which show an average assay of \$58 in gold, 20% copper, and 18 oz. silver. Many similar strikes have been made in this vicinity and the district promises to be one of the best in the country. In every case the ore had been high in grade and good in quantity.—The Oom Paul mine at Burke has been closed down and the pumps have been drawn. No reason for the shut-down has been made public; but it is understood that the general depression in business has been the cause. A force of about 12 men has been at work on this property.—A suit has been commenced against the Idora Mining Co. by Therrett Towles for the purpose of recovering something over \$1,000 of wages, which the company has failed to pay seven of its employees. The mine is an excellent one and already several shipments of high-grade ore have been made and the erection of a concentrator was contemplated in the near future. It is said that a sensational suit is about to be filed contesting the title to the property and in view of this it has been practically impossible to dispose of the treasury stock so as to finance the cost of development. The management reports that there are still 700,000 shares of stock in the treasury.

A one-machine compressor is about to be installed in

the Hector mine between Wallace and Burke. The drift in the property is now in about 400 ft. and it is calculated that the men still have about 300 ft. to go to reach the ore-shoot at a depth of approximately 600 ft. Some good ore has been encountered in the upper workings.—A rich strike of ore has just been made on the National mine in the Mullan district. The strike shows a fine body of copper ore and has not yet been fully explored. The ore was encountered in the shaft and at a depth of about 125 ft. Samples have been brought to Wallace and it is expected that these will assay from 10 to 25% copper. As soon as the full extent of the strike has been ascertained a tunnel will be driven.

The annual meeting of the stockholders of the Missoula Copper Co. was held at Mullan on November 5 and the following officers were elected: President, Robert McCormick; vice-president, C. A. Barnes; secretary, Thomas G. Kennedy; and these together with J. N. Thennes, H. Billberg, J. K. McLeod, and Harry Chaney compose the directorate. The report of Robert McCormick, who is also manager of the property, was read, and according to this 850 ft. of tunnel work has been completed and the company now proposes to run an extension to the Independent tunnel, a distance of about 750 ft., to get under the ore on the No. 2 tunnel. All the winter supplies have been laid in and a new transformer station will be built. The company's financial statement shows that there is over \$6,000 in the treasury.

Leadville, Colorado.

Ore Production.—Important Lawsuit.—Treatment of Zinc Ores.—The Weston Pass District.—Consolidation on Rock Hill.—Electric Power Transmission.

The production of the Leadville district during October amounted to 71,000 tons, about 60% of which was treated by the local smelters, and of this tonnage 8,000 tons of zinc ore was shipped to outside smelters.—A very important mining suit was recently settled at Washington when the Supreme Court refused to enter a petition for a re-hearing in the case of N. A. Munn against the Ibex Mining Co. This suit has been in the various courts for a number of years. It appears that about 15 years ago the Ibex Co. leased a group of claims adjacent to their ground; among these were the Little Stella, San Jose, Archer, and others, and in order to facilitate business transactions between the numerous owners of the various claims, the Archer consolidation was formed and the property placed in the hands of Clinton Reed as trustee. A bond and lease which was executed for a large sum was later taken up by the Ibex Co. N. A. Munn, one of the minority owners, brought suit on the basis of fraud and has fought the case almost continuously since.

At a late meeting of the stockholders of the New Monarch Mining Co. the directors elected were: J. C. Kortz, J. M. Thomas, T. H. Hogsett, G. A. Steinbremer, and W. H. Green.—The Bessie Wilgus mine on Rock hill, which closed down a few months since, has again resumed operations under the management of Robt. B. Estey. The owner, T. B. Wilgus, of Morgantown, W. Va., disposed of a large portion of his holdings to Eastern associates, who will proceed with the development work formerly outlined. The last work on the property was the sinking of the main shaft to a depth of 700 ft., at which point some driving was done but without opening new orebodies. Mr. Estey was the former manager, and is considered one of the best informed mining men in this district.—Development work on the Emerald property, near the Chalk ranch, continues, and a good vein of silver ore has been cut. The manager reports that the vein was cut at a point about 480 ft. from the portal of the adit.

The A Y & Minnie, one of the holdings of the Western Mining Co., has closed down the concentrating mill and made contracts with the Canon City plant to treat the lead-zinc ores. The Canon City plant is now handling 100 tons of this product per day, while the purer lead ores are being treated by the local smelter. A heavy demand by the smelters for silicious ore continues, and this demand has augmented the supply of that class of material from Fryer hill and vicinity.—Fred Hoffer is overhauling the shaft on the Hoffer property and is about ready to begin development work. A large pumping plant was installed last summer on the property and a promising contact was opened. It is upon this contact that the development work is to be pushed.—After several weeks' delay, due to a lost sinker, the drill-hole on the Neusitz placer has been cleared and a diamond-drill is being installed to proceed with the boring. It appears that the hole is at or near the solid formation at a depth of 620 ft.—The lessees on the old Seneca property, L. Bolton, A. Wallace, and L. E. Jorstad, are shipping from a strong shoot of iron ore at the 300-ft. level, which runs 10 oz. silver and 45 to 50% excess iron.

The season's work at Weston Pass has been most satisfactory. The Ruby opened a good body of iron ore and shipments will be made before winter puts an end to operations there. Also, the shaft on the Collin Campbell cut a workable ore-shoot. On the whole, mining men regard the Weston Pass as a very promising district since the silver-lead deposits thus far opened indicate both strength and continuity.—A Rock hill consolidation styled the Bolcoath Leasing & Exploration Co. has been incorporated and controls the following properties: Only Chance, Oro City, Ben Burb, Great O'Sullivan, and Raven. The Ben Burb will be developed through the Raven, and a force of men has been put to work on the Only Chance to prepare the workings for operation. This ground is regarded as exceptionally promising, and the work planned will be the first systematic development done on this property. Recent shipments have been made from the Only Chance and Raven; these proved the ore to be of good grade.—The work on the Mammoth property, while not resulting in the early success anticipated by the promoters, is being vigorously prosecuted. The vein, which was cut between the 500 and 600-ft. levels, is being prospected and the drift on that shoot is now in about 75 ft. Throughout this distance the shoot is from two to four feet wide and is rich in silver. The drift at the 600-ft. level is being run west of the porphyry dike and at the same time one drift is being run to the east and one to the south from near this level. J. A. Shinn has been recently appointed the manager of this property. There is now less trouble from water than at any date since the Wellington Co. took hold of the Mammoth property. While the pumping equipment is capable of handling 1,000 gal. per min., it is only being worked at about half that capacity.

Electric transmission lines are being extended from the Leadville power-plant to Kokomo and Robinson; the power contracts call for power in those districts to be delivered not later than December 1.—The Fanny Rawlings continues to make large shipments of copper sulphide ores and development work is planned on an extensive scale for the future. A winze is being sunk on the claim nearest the Ibex property, which will enable development work to proceed from a point below the present levels. An electric pump will be installed to handle the large flow of water.—The Covey lease on the Hibsche property is still shipping a large tonnage of carbonate lead and iron ores. A drift that was run to the south above the Cambrian quartzite has cut a strong shoot, probably an extension of the Wolcott orebody.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A GOOD, WELL-CALENDERED RUBBER BELTING made with 30-oz. duck and new rubber has a thickness of about $\frac{1}{8}$ in. per ply. The safe working strain for a belt 1 in. wide varies from 15 lb. per ply for a 3-ply belt up to 18 lb. for an 8-ply belt.

THERE are six common methods of testing lubricants: For chemical content; for specific gravity; for relative viscosity when new; for gumming action; for flashing and burning points; and by the testing machine. The last is the best method because it approximates working conditions. Oil-testing machines consist of a pendulum hanging in capped bearings, the pressure in which can be regulated by means of screws. When the journal is rotated the pendulum points to a graduated scale, from which the friction per square inch of journal can be read directly.

THE question regarding the water rights to a spring cannot be satisfactorily answered without more definite information. It will be necessary to know in what State or Territory the spring is situated, as the laws regulating the right to appropriate, and the manner of appropriating, water are not the same in all parts of the arid West. The laws of Nevada differ from those of Arizona and both from the laws of California. It will likewise be necessary to know whether the spring in question rises to the surface and flows in a definite channel or is merely formed by percolating waters.

WITH the exception of one mine all the mines at present worked in Rhodesia were worked long ago by the 'ancients.' Often the smoke marks on the rock faces, and even the charcoal from the old fires of these ancient miners are found on clearing out an old pit. Conchoidal markings on the rock surfaces are characteristic of the former breaking of the rock by means of fire and water. The deepest of these ancient workings on the veins is 250 ft. in depth; many of these ancient pits were 100 ft. deep. In some places the 'ancients' did considerable placer mining; their tailings are so poor as to be worthless now.

It is difficult to make electrical machinery fool-proof, and this is one of the reasons that electric drills have never been very successful about mines. Frequently an electric drill, when run by the company experts sent to introduce them, is highly successful, but when they are placed in the hands of the average miner, who knows practically nothing about electricity and who is generally operating the drill in constant fear of a shock, the drill quickly gets out of order. Apparently the shock of drilling and the rough usage that rock-drills receive underground is too great a strain for electric machinery to withstand.

AIR-COMPRESSION by means of falling water is simple, efficient, and practical. The cost of installation and of operation is small. There are several marked advantages of this method of air-compression; the compression is isothermal and consequently it does not carry any excess moisture to be condensed later in the pipes, air-drills, etc.; the air is pure and is not contaminated with evaporated or burned engine-oil; as there are no moving parts in such a plant, practically no attention is necessary during its operation. The efficiency of a plant using this method is from 75 to 83% of the theoretically possible effi-

ciency obtainable from the water. The use of this method is restricted by patent rights but recently several such installations have been made, notably the one at the Victoria mine in the Lake Superior region.

THE mining laws of Rhodesia are quite similar to those of United States. The mining engineers, who were asked to frame mining laws for Rhodesia, upon investigation found that they were handicapped in their selection. Cecil Rhodes had promised the early prospectors that they could follow their veins wherever they went in depth. Consequently it was necessary to accept the law of the apex. Much of the litigation resulting in the United States from the apex law has been avoided by providing that the first locator always has prior rights no matter whether he is located on the main vein or only on a stringer.

THE use of electricity about mines increases in importance each year. The best pumping practice in deep mines favors the use of electrically driven centrifugal or turbine pumps; many electric locomotives are used for underground haulage; frequently ventilating fans are driven by electricity; the stations and drifts at all large mines are now electric lighted; electric push-buttons and electric flash-signals have taken the place of the bell-rope and rappings on pipes; electric hoists are now becoming more popular and increase in size each year. But electric drills are still as unsatisfactory as ever except that a combination electric-air drill is proving satisfactory.

IN the absence of any State law in California defining the manner in which a mining claim is to be monumented, the provisions of the Federal law must be followed. This requires that the claim should be marked on the ground so that its boundaries may be readily traced. As the object of the requirement is to enable the next comer to determine by surface inspection where the boundaries of the previously located claim are, the marking should be by substantial posts and monuments at the four corners at least, and, if in a wooded or bushy country, the lines between the corners should be blazed or the brush removed. This is, next to discovery, the most important act in the perfection of a lode mining location. While the courts are very lenient in construing the acts of a locator who is the first discoverer of a mine, great care should be taken to monument the claim properly.

THE cost of patenting mining claims will depend largely upon the locality and its proximity to centres of population. The only charges fixed by law are the Surveyor-General's fees, the fees of the Register of the Land Office, and the Government price of the land. Deputy mineral surveyors usually charge a *per diem*, ranging from \$10 to \$20 per day and transportation. Charges for publication vary in different papers, as do the charges of attorneys. An estimate based upon a recent patent application may be given by way of illustration, covering a group of eight contiguous lode-claims of the full size, 20 acres each:

Surveyor-General's fees, \$25 per claim.....	\$ 200
Deputy mineral surveyor " " "	200
Attorney's fees.....	300
Publication of notices.....	160
Purchase price of land.....	800
Register of Land Office	10
Total.....	\$1,670

As a condition precedent to the issuance of a patent, law requires \$500 worth of work or improvements for each claim aggregating \$4,000 for a group containing eight claims. This, of course, is in addition to the schedule of fees above set forth.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Grass Roots.

The Editor:

Sir—Long acquaintance with your writings and editorial policy ill fitted me for the shock which I have just experienced in seeing that you have lent your columns to the education of fake mining promoters. As soon would I expect to see in 'Concentrates' advice as to the proper milling of bogus dollars or the proper pickle to give brass twenty-dollar pieces so as to make them more effective.

Under the head of 'Technical Writing' was a letter signed by G. B. W., in which he takes issue with you for using the expression 'grass roots.' It appears from the letter referred to that this expression, with others like 'red metal,' 'yellow metal,' and 'proposition,' is a splendid danger signal to warn the would-be investor. Hence they should be all tabooed by "honest miners" and severely left to the fake promoter.

I think, if such is the case, that a grave mistake was made in thus publicly exposing the trick. While it is proper to expose the fake, one should be very careful as to how it is done. It should have been made the object of a private circular to your subscribers. For now that the faker knows we are on to his private *argot*, he will abandon it and either use good English up to the standard of G. B. W., or invent a new shibboleth which might be more effective than the old one. Then would the poor would-be investor be lost indeed; especially if the promoter commenced to dip his pen into the well of pure English undefiled. Great molders of public opinion have all been purists. John Bright and Mark Twain owe their influence to the purity of their English. Just think of the awful effect if promoters ceased to write of 'grass roots' and modeled their style on the excellent letters that appear in the MINING AND SCIENTIFIC PRESS! Investors would cease to be 'would-be' and become so in fact. Widows and orphans, together with the poor seamstress, would be robbed of their little all in increasing numbers and the wicked promoter would flourish like the proverbial bay tree.

Now as to the poor old terms 'red metal' and 'yellow metal,' I have nothing to say. But I do plead for 'grass roots.' Please let it remain respectable and don't prohibit it yet awhile on the MINING AND SCIENTIFIC PRESS 'style sheet.' Really there is a place for it, for it is not synonymous with 'surface.' Let us be exact and scientific as G. B. W. demands. Let us examine the evidence. First, how deep has G. B. W. found grass roots? Second, how does he know they were grass roots? Third, what are grasses? I have seen roots in mine workings coming from surface to depths of more than 100 ft., but I don't believe they were roots of grasses, but looked roots of water-seeking shrubs or trees. The longest roots of small plants I have seen were of alfalfa, but, not being a botanist, I don't know whether these are strictly grasses or not. Anyway, this case is out of count as I never found a vein in an alfalfa patch or alfalfa growing on a vein. Certainly 'grass roots' don't mean 'surface.' The surface is the exterior part of anything and grass roots don't grow on the superficies but underground. So G. B. W. is inexact again.

I am now opening up a vein in granite covered with 12 ft. or more of soil in which are innumerable grass roots, shrub and tree roots, etc. The granite is hard and no grass roots can penetrate. Now this vein does

not come to surface as I understand the word, although in the 'new' science it may be re-defined. Where does the vein come to? Am I a nature faker if I say it comes to grass roots? Let us be sensible in our use of language and because scoundrels misuse a good old word, the meaning of which we all understand, I see no reason for us all to stop using it. We are told on good authority that the devil quoted scripture. Are we all to be debarred from the use of a goodly text?

Now for my part I am going to say 'grass roots' (and when provoked even write grass roots) once in a while, and when I want to get into a fight on the modern mining terminology I shall look for a worthier foe.

INGENIERO.

Las Chivas, Chihuahua, Mexico, October 18.

The Barnes King Affair.

The Editor:

Sir—I wish to point out that I had absolutely no connection with the Barnes King property prior to the flotation of the Barnes King Development Co., nor did I make a report of any kind on the property previous to December 22, 1906. I further wish to emphatically state that I made no reports to aid or in any way to assist in its flotation, and that the company was formed before I left to inspect the property for the first time. I was not engaged as an examining expert for either the promoters or the company itself to place a valuation upon the mine. A copy of Mr. William Word's report was shown to me, and I was asked to give the company my services as consulting engineer. I consented to do so, and gave the greater part of my time to its affairs for the first six months. I was instructed to forward my reports to the president of the company and to receive from him directions as to the policy to be adopted regarding operations.

I made a preliminary report dated December 22, 1906, after an inspection of the property. This report was merely one referring to the existing conditions of the property as they appeared at that time and did not go into the matter of values except in a casual way. I was never at any time so favorably impressed with the assay values of the property as others appeared to be.

In January of the present year I advised that the property was very low-grade, and on April 3 I presented a report giving measurements and values, which showed that I estimated 29,324 tons, showing a gross value of \$121,798. This was all the ore I estimated blocked out above \$3. This report was sent to the president of the company accompanied by assay maps. There is a great quantity of ore which will assay under \$3 and the engineering problem is to make this ore pay.

The president was continuously in full possession of all facts regarding the property. Assay-sheets were mailed regularly to New York, together with cost-sheets and full financial statements, and it is difficult for me to understand why the directors appear to have been so much in the dark regarding the value of the mine. All I can say is that all information was sent regularly from the mine and was in the hands of the president, and financial accounts of the mine went also regularly to the treasurer. The policy and the work carried out was that directed and authorized by the president of the company. The conditions at the mine, however, did not satisfy me, and in May I requested to be relieved of my responsibility, and frequently made further applications from that time on. It is absolutely untrue that my resignation was requested by the board or the president, and it was not until the stockholders' meeting in August that I succeeded in being notified that I could be relieved of a position which

was very distasteful to me on account of the low-grade nature of the mines. I desired to see another property taken up in order to relieve stockholders who had invested in the Barnes King Development Co., and it was for this purpose that I remained in the company's service longer than I intended. When I found that this plan could not be put into effect, I absolutely refused to further act as its engineer.

I had no control whatever or any interest in the company's financial affairs, and did not know their condition. My connection with the property was purely professional, and I was in a similar position to the mine as a doctor is to a sick patient who has little hope of recovery, but who still needs attention. I was never invited to attend a meeting of the directors, but had to transact all my business with the president directly, and to him I tendered all of the engineering advice that the company was entitled to.

Professional considerations require that an engineer can only report or receive instructions from such officers or persons as he is directed. Personally, I feel that it is not my part to discuss this matter further, but merely desire to point out my relation with the company, which has been misunderstood. My professional work is open to criticism by any one, as both engineer and layman are entitled to an expression of opinion on the work already done, but I must allow the public to form their own conclusions regarding the present state of the company's affairs. About its promotion I know absolutely nothing, but believe the mine was purchased in good faith.

Greek Gifts.

The Editor:

Sir—I like your article about Andrew Carnegie and his gifts. It is the pride of my life to know that the parish in which I live, Marylebone, refused his offer of a free library. Other parishes in the London district and elsewhere are saddled with the cost of extra upkeep, much to the ratepayers' distress. Since the progressives were routed at the County Council and Borough Council elections earlier this year, the free libraries have not been allowed to spend public money so prodigally.

Carnegie's gifts remind me of the old story, which no doubt is familiar to you, of the man who plodded through life diligently and raised a family as a man ought to, and always managed, by strict attention to duty and by the full use of such abilities as were allotted to him, to pay his way and put a little aside for unforeseen eventualities. His good conduct and general rectitude marked him out among his fellows, and one day his admiring friends made him a gift, which took the form of a really first-class upright grand piano. It had such a lovely rosewood case, and it made his furniture, which was only whitewood stained mahogany, look rather shabby. It worried him to see his wife discontented with the chairs that had hitherto done duty, and so he bought a new suite, which cost him \$150. The suite was upholstered in best plush and the carpet suffered in comparison. And so on. Finally the poor man was saddled with the cost of new furniture and furnishings generally throughout the house, silk skirts for his wife, music lessons for his daughters, etc. I forget what happened to the man, but it was either bankruptcy, splits and hatred among the members of his family, or suicide, perhaps all three.

This letter is not exactly suitable for publication, but if you should print it, let me sign myself

A BELIEVER IN FREE GIFTS.

London, October 11.

Professional Customs.

[The questions to which reference is made in these letters will be found in our issues of October 5 and 12.—Editor.]

The Editor:

Sir—My views on the "searching questions" which you sent me, regarding professional ethics and procedure, are as follows:

1. In the hypothetical case given, I should think it would be better to name a fee for the examination, assuming that it could be completed within one month, and a *per diem* charge for all additional time occupied in the work.

2. I do not think it advisable or necessary to have a written contract with the employer, and if the engineer does not consider that the letter or telegram engaging him for the work is sufficient, it would be better for him not to undertake it at all.

3. I should think it quite proper to ask for a retainer, certainly sufficiently large to cover the actual outlay for traveling and living expenses, before starting.

4. It is usual, I think, to charge the client with the cost of equipment, although I think the engineer should always furnish his own sampling outfit and instruments.

5. (a) I do not consider that any of the items enumerated should be charged to the client.

(b) The engineer, if his expenses are for account of the client, as is usual, is, I think, entitled to the best first-class passage on train or shipboard, and also at hotels in the mining district. In the event of his being in a large city, however, at his employer's expense, I think he should either stop at a moderate-price hotel, or make up the difference himself.

(c) I do not think this procedure advisable under any circumstance.

(d) I think a detailed expense account covering all items advisable.

(e) I do not think it customary to take vouchers for traveling or living expenses, although this could be well done if the sums are large.

(f) I should not consider it advisable to charge these expenses.

(g) The statement of expenses is usually rendered at the end of the engagement.

6. The client is certainly entitled to any information that the engineer may have at any stage of the engagement, but the latter cannot be too careful in committing himself to any opinion, until he has thoroughly investigated all the facts and data, any part of which might cause him to change or modify his opinion later.

7. The young engineer will avoid much misunderstanding and possible pitfalls, if he keeps firmly established in his mind, that the results of his examination are the property of his client, and that such information can only be legitimately used with their consent; in the event of his wishing to buy shares in the property in question, an excellent way of avoiding any misunderstanding, and also showing his belief in his own judgment, is to buy the shares through his clients and with their knowledge and acquiescence.

8. The remarks under No. 7 will also apply to this question.

9. There certainly should be no objection to publishing a description of the district visited after obtaining the consent of the client.

10. It is often expected of an engineer to say 'Yes' or 'No,' but this is sometimes impossible; certainly it would be to reach "a definite conclusion" if "the facts obtainable are insufficient for an intelligent opinion." If clearing out the drifts will enable him to do this and

he has been asked to make his examinations as complete as possible, this work should certainly be done; unwatering shafts and opening caved ground is usually a serious piece of work and should not be undertaken at their expense without the direct authorization of the client.

PERCY L. FEARN.

New York, October 14.

The Editor:

Sir—In reply to the letter dated September 18, 1907, from your correspondent T. S.:

1. We should say it is decidedly the better and more usual practice to charge a fee.

2. The answer to this question depends largely on circumstances. A letter written in England and stamped with a sixpenny Inland Revenue stamp, within the prescribed limit of time (a fortnight), is, we believe, as binding as a contract; but it is more advisable to have the terms of the agreement set out in the form of a proper legal document, and if the letter is from a company it should embody the terms of a minute passed at a properly constituted board meeting. It is questionable whether a telegram would constitute a binding contract; in any case, it would be very difficult to define the scope of the contract in this way, and you would naturally require to be certain of the good faith and financial stability of the sender of the message.

3. Yes. A lump sum is often asked, and paid by the employers to cover expenses of the trip.

4. This depends on the nature of the contract, but the engineer is, in our opinion, certainly entitled to charge for all labor and equipment necessary for carrying out the work thoroughly.

5. (a) We should not consider laundry bills and tobacco as legitimate expense items. Reasonable tips would probably be allowed. Also ammunition and medicine, if there was any occasion to employ them. A proper account should be kept and handed in, and the various items would then be passed or struck out.

(b) This, again, may be a matter of arrangement, but the engineer would expect, if acting alone or in charge of an expedition, to be allowed a first-class passage and the best accommodation at hotels.

(c) He has certainly no right to travel second-class or steerage, if paid to travel first-class.

(d) The account should be kept as minutely as possible, but may be summarized for presentation. If properly kept, there need be no charge for incidentals, and any items that might be questioned should be shown.

(e) Certainly we think that vouchers should be obtained whenever possible.

(f) Under exceptional circumstances, expenses incurred in entertainments might be permissible, but it would have to be shown that it was on the employer's behalf.

(g) The statement of account would generally be presented when the work is completed, but this, again, is subject to arrangement.

6. We do not think it is a good plan to forestall the final report by sending it in installments. The contract should leave the engineer a free hand in this matter.

7. We should say "Certainly not" to these questions referring to transactions in the shares.

8. It is impossible to reconcile the dual position that the writer assumes and without a special arrangement, any work done on behalf of others, or the acquisition of property, or options over property on his own behalf, would be liable to severe criticism, and place him in a very false position, even if acting in perfectly good faith.

9. We see no objection to publication of general information about the district acquired during the engineer's visit. If the employers are not likely to suffer direct or

indirect injury thereby, they are not at all likely to object.

10. It is often impossible to form a definite opinion, and he may have to advise further development or run the risk of turning down a good property. With regard to the last question, it would in our opinion be necessary to obtain the authority for special work of the kind referred to.

CHARLETON, DICKINSON & Co.

London, October 18.

The Wild-Cats of Ontario.

The Editor:

Sir—In reference to your letter from Ontario that Law & Co., the promoters of the Blue Bird, Blue Bell, etc., had received a warning from the Attorney General of Ontario as to the illegality of the advertisements they are publishing broadcast in Canada and the United States, *The Canadian Mining Journal* might go further and expose what I would term the Ontario conspiracy.

This is a gigantic conspiracy among the people of Northern Ontario to spread, and pretend to believe, the false reports emanating from irresponsible prospectors and fortune hunters. Men whose names have been above reproach think nothing of spreading these perversions and of profiting thereby. I have known such people to show specimens of ore from the Western States as coming from Ontario, selling claims and stock on the misrepresentation. I have known at least two claims at Larder Lake that were sold on a sample of ore that originally came from outside of Ontario. In respect to Law & Co., it will be found that they have protected themselves by reports from irresponsible adventurers, and publish these reports as true, and the only way to get at them is to prove that these reports were known to be false. This should not be difficult.

This whole Northern Ontario excitement is based upon the surface richness of the territory immediately surrounding the town of Cobalt. I say the "surface" richness advisedly, because so far it has been proved to be at the surface or near the surface only, and in no mine at Cobalt has rich ore been found below 300 ft. The Tretheway stopped sinking at 100 ft. because the vein became poor; hundreds of feet of cross-cutting has been done with good results, for many blind veins occur in the Cobalt territory which can only be found by cross-cutting at a shallow depth. The Silver Queen gave up work below 75 ft., because the rich vein did not extend down to the 125-ft. level. They also have found blind veins of great richness by cross-cutting on the 75-ft. level. I am told that the O'Brien mine never took out ore below the 175-ft. level. The McKinley-Darragh workings are not below 150 ft., while the La Rose at 300 ft. is a closed book, because the ore gets poor below 200 feet.

While the Cobalt veins are very rich near the surface, and from all indications are not of any great depth, the Larder Lake veins of quartz are poor on the surface and probably poor in depth. Those I saw were both poor and very shallow, some giving out within 10 ft. of the surface, others, which I did not see, had shafts reported to be from 60 to 150 ft. deep, but low-grade. The reports of high assays I take to be fiction or the assays of samples that originally came from elsewhere. These irresponsible assays and reports are published in the Canadian papers with the intent to deceive, for the Canadians know well enough that the capital to develop their country must come from the States.

The point I wish to make is that reports of finds of mineral from Northern Ontario must be discredited altogether. Usually where there is smoke there is fire, but in this case one generally finds frost.

D. A.

New York, October 21.

Mining in Australasia.

Written for the MINING AND SCIENTIFIC PRESS
By H. L. WILKINSON.

During the past year mining has been extremely prosperous in Australasia, and a record has been made for the value of mineral production, as the following figures will show:

1896	£13,730,532	1902	£25,235,229
1897	16,042,383	1903	27,315,366
1898	18,223,335	1904	27,559,210
1899	24,857,809	1905	28,545,118
1900	24,103,329	1906	30,410,000
1901	24,972,007		

The figures include the value of coal, shale, limestone, and similar products that have been raised, but compared with the metallic production these are small.

It will thus be seen that the mineral production is slightly more than double what it was 10 years ago, and there has been an increase of about £1,500,000 over the figures of 1905. It is more than probable that notwithstanding a considerable decrease in the gold yield in the future, the mineral production for the year 1907 and afterward will show further growth.

Considering the various States of the Commonwealth and New Zealand individually, it is seen that New South Wales and West Australia are responsible for nearly half the total mineral production. The following figures will show the variations in production for the past few years:

	1898. £.	1900. £.	1902. £.	1904. £.	1906. £.
New South Wales.....	4,801,248	6,460,968	5,078,029	6,220,051	7,912,716
West Australia.....	3,939,382	6,179,612	8,094,580	8,621,595	7,931,187
Queensland.....	2,962,711	3,180,164	3,310,600	3,704,241	4,198,647
Victoria.....	3,466,772	3,380,244	3,294,934	3,420,136	3,382,581
Tasmania.....	1,070,894	1,676,166	1,658,996	1,494,418	2,257,147
South Australia.....	349,436	515,128	576,468	652,515	977,063
Australian Commonwealth.....	£16,650,443	£21,400,182	£22,013,607	£24,119,976	£26,659,841
New Zealand.....	1,572,892	2,703,147	3,221,622	3,439,234	3,750,000
Total.....	£18,223,335	£24,103,329	£25,235,229	£27,559,210	£30,410,000

The figures for New Zealand include about £500,000 of Kauri gum extracted from the earth each year.

If these figures be read with those included in the following table, which shows the value of production of the principal metals in each State, some idea can be formed as to the items which have particularly contributed toward the increase in metal production, and some deductions may be made in respect to the future of different parts of Australia from a mining point of view.

Analyzing these figures, and taking the various metals in the order of their importance, the decrease in gold can be seen in all the States; and unless some new field be

discovered in the unexplored parts of Australia, this decrease in yield must continue, and at a more rapid rate. It is only necessary to consider the condition of the principal mining regions of Australia, where working costs have been brought down to nearly a minimum, to ascertain that the gold mining industry is on the down grade, though it is not anticipated that there will be any great decrease for a considerable time on account of the wide distribution of the mines.

WESTERN AUSTRALIA.

Taking the districts in order of their importance, it is seen that Kalgoorlie, which in 1906 produced £4,000,000, has passed its zenith, as regards the annual gold yield, in value of ore reserves, and the prospect of new developments. As the working costs at the Kalgoorlie mines are now at their minimum, there does not now exist the large reserve that most districts possess while a lowering of the working costs is still possible.

The accompanying returns summarize the position of the principal mines at Kalgoorlie; these mines are responsible for nine-tenths of the yield from this district, and for one-half the yield of West Australia. As will be seen, the Kalgoorlie mines mentioned, together with the Great Fingall Consolidated and the Sons of Gwalia, were responsible in 1906 for £1,933,786 in dividends out of a total of £1,992,062 paid in West Australia. Further,

these mines, owing to their large production compared with the number of points of possible future development, are more subject to large variation in yield than a great number of the small mines that make up the balance of the yield of West Australia.

When it is considered that these figures relate to mines which have proved to be most persistent in the value and width of their ore in depth, it is apparent that the gold yield in this State promises to decrease largely; and as there have been no new finds within the past five years, there are no indications of other mines to take the place of those approaching exhaustion.

Gold.....	280,015	254,963	123,648	108,707	1,987,507	2,261,918	17,928,478	16,928,145
Copper.....	507,066	934,924	432,062	743,570			1,658,206	3,434,694
Silver.....								
Lead.....	396,110	462,443	1,387	12,982	112,875	125,000	2,688,676	3,607,683
Zinc.....							161,548	292,806
Tin.....	275,738	557,366	27,085	36,907			845,483	1,509,488
Coal.....	20,878	44,962			826,207	850,000	3,154,955	3,543,751
Other minerals.....	10,611	2,589	68,362	74,897	512,651		1,323,456	1,353,031
Totals.....	£1,489,418	£2,257,147	£652,545	£977,063	£3,439,234	£3,750,000	£27,559,210	£30,410,000

In the item 'other minerals' the values stated are only approximate, and this accounts for any discrepancies in the totals. In the case of New Zealand, 'other minerals' include about £500,000 worth of Kauri gum annually. In the above table the year 1904 has been taken for comparison purposes, as the conditions appertaining to that year were more typical of the years previous to 1906 than those of the year 1905.

VICTORIA.

The State of next importance in the production of gold is Victoria, which has now produced 70,000,000 oz. gold since the discovery in 1851. Though the indications of a decreasing yield are not as obvious as in West Australia, yet the great depth to which mining has reached and the generally poor results, together with the exhaustion of the superficial deposits, point to conditions which the gold mining industry has not previously experienced, and which must have a detrimental effect on the future yield, or at any rate on the profits. This view is supported by the fact that during 1907 the yield for the first six months of the year is 50,000 oz. less than in the corresponding period in 1906. There are, however, great deposits of buried auriferous gravel all over the State, and the successful exploration of these 'deep leads' would give a great revival to mining and would entirely alter the future of the industry, as the quantities of this gravel is very great, and up to now they have been but little exploited. The dredging industry has given a new source of gold, and it is probable that the yield from dredges and hydraulic sluicing plants will increase. The following are the yields from dredges during the past few years: 1900, 25,026 oz.; 1902, 31,622 oz.; 1904, 52,732 oz.; 1906, 85,271 oz. The average grade of the gravel worked in 1906 was 2.36 gr. per cubic yard.

There is, however, not the same permanency of production that there is in Victoria, and the decrease in the gold yield, which has been going on since 1903, is likely to continue. The profits derived from gold mining will decrease at a more rapid rate, as the dividends were almost wholly contributed by a few mines at Charters Towers and Gympie, together with the Mount Morgan mine, which is rapidly turning into a copper proposition.

The following statistics will show the relative positions of the principal mines during the years 1904 and 1906:

	1904.			1906.		
	Quartz crushed.	Yield.	Divi- dends.	Quartz crushed.	Yield.	Divi- dends.

The statistics of yields and profits from the gold mines of the various districts are as follows:

District.	1904.				1906.			
	Allu- vial gold.	Vein gold.	Av. per ton.	Total divi- dends.	Allu- vial gold.	Vein gold.	Av. per ton.	Total divi- dends.
	Oz.	Oz.	Dwt.	£	Oz.	Oz.	Dwt.	£
Bendigo	12,745	230,134	10.1	382,321	9,269	211,916	8.8	251,727
Ballarat	41,712	104,290	6.0	77,315	51,851	112,184	5.3	62,700
Beech- worth	8,083	37,502	15.1	57,510	103,514	31,297	10.2	65,598
Ararat	13,085	11,458	5.9	10,166	8,638	16,260	5.1
Marybor- ough	41,785	43,363	7.3	37,000	38,594	16,672	5.1	10,069
Castle- maine	26,860	50,309	9.5	17,240	32,990	66,396	12.8	37,701
Gippsland	6,820	59,900	21.9	41,841	8,777	88,402	18.6	36,896
Total	231,092	536,929	621,397	253,696	568,130	481,793

The average per ton refers only to the lode ore treated.

QUEENSLAND.

What has been said in respect to gold mining in Victoria applies equally well to Queensland, as the two States have similar characteristics in their mines and methods.

The other districts produced under 100,000 oz. gold per annum; of which Croydon and Ravenswood produced 80,000 oz. These figures are slightly on the increase, but not to any notable extent. However, with the completion of the railway extensions now under construction, the yield from the outside fields will increase, but it is unlikely that this increase will compensate for the decrease which must take place in the old districts with the exhaustion of the principal mines at Charters Towers and Gympie.

SOUTH AUSTRALIA AND TASMANIA.

The States of South Australia and Tasmania are unimportant in their gold production, and were responsible for yields of only £85,000 and £251,963, respectively.

The principal contributor in Tasmania was the Mount Lyell Co., where gold to the extent of between 1 and 2 dwt. per ton of ore is recovered in the copper smelting. The Tasmania, at Beaconsfield, which is an isolated mine, has recently improved its plant, and notwith-

standing having to raise 4,000,000 gal. of water per day for a lift of 2,000 ft., is once more producing gold profitably. The Mount Lyell and Tasmania yielded about 25,000 and 30,000 oz. respectively, in 1906.

NEW ZEALAND.

The total value of gold won in New Zealand during the past six years is as follows:

1901.....	£1,753,783	1903.....	£2,037,831	1905.....	£2,093,936
1902.....	1,951,433	1904.....	1,987,501	1906.....	2,284,918
Total since discovery of gold in 1857, £69,495,502.					

From these figures it is seen that in 1906 the rate of increase has been more than maintained. There is, however, every probability of this increase being halted, as the gravel deposits now being dredged are becoming exhausted.

The number of dredging plants at work in New Zealand is now 172. This is a slight decrease on previous years, due no doubt to the stoppage of a number that commenced work during the dredging boom between 1895 and 1900. In 1895 there were only 74 dredges at work.

Vein mining is practically confined to the North Island, where the Waihi and Talisman Consolidated contributed the greater part of the output of gold.

NEW SOUTH WALES.

This State is maintaining the yield it has been keeping up for the past 13 years, and there is every probability that for some considerable time the annual yield will be well maintained. This satisfactory position is due to the wide distribution of production. These conditions have rather tended to delay the prospecting of the country, for the concentration of mines in one or two districts encourages rapid development. For these reasons the gold mines of New South Wales are much younger than those of Victoria and Queensland, and speaking generally, the yield is more likely to be maintained.

The principal gold producing district is Cobar, which produced 60,463 oz. in 1906. At Cobar most of the large gold veins become copper-bearing in depth, with a considerable loss in gold contents. There are several large mines, however, without a trace of copper. The most productive of these is the Mt. Boppy, which produced 29,983 oz. This mine has large reserves, and it is likely to maintain the present output. On account of the unprospected state of the country in the vicinity of Cobar, there is every probability of new gold discoveries. The Mount Boppy mine itself was found only seven years ago, and has already produced £456,571, though no ore has as yet been taken out below the 300-ft. level.

As the Waihi is one of the greatest mines in the world, and has the most assured future of any gold mine in Australia, the following statistics may be of interest:

	Treated.	Yield.	Value per ton.	Profit.
	Tons.	£	Shillings.	£
To Dec. 1891.....	Not known	70,086		
1895.....	33,670	120,335	71.5	65,966
1900.....	112,012	317,902	56.5	163,511
1905.....	266,545	728,521	54.5	346,554
1906.....	203,630	837,927	57.0	397,241
Total.....		£5,411,628		£2,442,708

The Talisman Consolidated and the Progress mines at Reefton, in the South Island, are the other two large mines in New Zealand. The following are particulars of the yield of the Talisman Consolidated:

	Treated.	Yield.	Average per ton.
	Tons.	£	Shillings.
1905.....	45,520	145,777	64
1906.....	46,417	160,119	69

The gold dredging industry in this State was responsi-

ble for 33,218 oz., and there is every probability of this yield being maintained.

The Progress mines at Reefton produce about £100,000 annually, at a profit of £30,000.

MILD STEEL has a rather definite elastic limit and yield-point beyond which the character of its action changes in a marked way. Beyond the yield-point the rate of stretch in tension becomes almost at once one hundred or more times as much as it was within the elastic limit. In compression, the ultimate strength of mild steel is not far beyond its elastic limit. It is evident that a structure made up of this material will distort and fail when a load producing stresses not much greater than the elastic limit is placed upon it. The elastic limit of mild steel has a small range, its value running from 50 to 65% of the ultimate strength, depending upon the size of the piece, method of rolling, etc., and the steel is made under such conditions that little risk is taken in choosing a value for a particular size and shape of piece. The modulus of elasticity of steel is also quite uniform. It may be said then, that the properties of this material, with proper inspection, are fairly definitely known. When the factor of safety of a structure is based upon ultimate strength of mild steel, it assumed that the factor of safety named in the calculations is nearly double the factor which will bring actual failure under the conditions assumed to exist in the structure. For a plastic material, or a material not having a definite elastic limit, or at any rate one for which the stress varies directly as the deformation for at best only a small part of the ultimate strength of the material, a different consideration must be given. For such materials, the effect of lack of uniformity of the material, the effect of increased deformation, of repetitive loading, of time, and of other factors must be considered.

IN the rooms of the Commercial Club at Grants Pass, Oregon, there is exhibited a large Indian mortar found at a depth of 58 ft. in a gravel-bank worked by the Deep Gravel Mining Co., of Waldo, Oregon. This mortar is quite similar to those in use among the Indians when white men first came to southern Oregon. Near the mortar is also exhibited a flat stone, about 3 in. thick and 12 or 14 in. diam., having a broad shallow depression in the centre of it. This was found at the same hydraulic mine at a depth of 51 ft. At the time of discovery eight flakes of gold were found ground into the pores of this stone. It is supposed that the Indians pulverized gold-bearing quartz upon this stone in order to separate the gold from the quartz. Whether the Indians used such an implement merely in treating the gold-bearing quartz they found in streams or used it in treating gold quartz that they had mined, is not indicated. But, owing to the many rich pockets of gold-bearing quartz found at surface in the hills of southern Oregon, it seems quite probable that the latter use was made of this stone. Besides, the stone appears to have been much used, and that would not have been so probable if only quartz-bearing nuggets were pounded on this stone. If such was the use of the stone, the writer suggests this is the first indication of quartz mining in the United States.

DIRECT current electricity is generally used about mines. This is partly because of the fact that alternating machinery was not well developed when electricity was introduced in mines; besides, electricity is generally developed at or near the mine and consequently direct current is used. But the rapid increase in the efficiency of long power transmission has caused the adoption of much alternating machinery about mines.

A Make-Shift Stamp-Mill.

The accompanying photograph illustrates the resourcefulness of the Australian prospector. It shows a rough-and-ready stamp erected in the desert region of Western Australia. A windlass handle turns a round timber to which cross-pieces are fixed so as to serve as a fly-wheel. A piece of bent corrugated iron serves as a chute to feed the extemporized mortar. The frame-work looks a bit rough but it is the best available in the locality, where the only timber is obtained from scrubby trees of the acacia family. This photograph is one of the few things that escaped the San Francisco fire; the description that was prepared to accompany it was burnt.

ALCHEMY.—The writings of the alchemists were very numerous, and very mystical, and the recipes are quite unintelligible. Yet the evidence of successful transmutation, presented by the various writers, is overwhelming; and the writers appear to be themselves convinced of its reliability. There were certain facts known to them which gave some actual support to the possibility of transmutation; the deposition of copper on articles of iron left in certain mine waters, and the corrosion of copper into yellow brass on heating it with calamine and charcoal—both these phenomena were known to the ancient alchemist. Later came the knowledge that bronze could be formed from heating copper with cassiterite and charcoal, and there are records to show that the alchemist was familiar with such processes as the whitening of copper by arsenic, the cupelling of lead, whereby the globule of silver or gold was left behind, or the obtaining of precious metals by the distillation of the mercury which contained them. These facts had the appearance of actual transmutation, and many crafty knaves took advantage of the credulity of the times. Nevertheless, much chemical knowledge was accumulated during those centuries; metallurgy advanced, and pharmaceutical chemistry profited greatly. In Egypt, the mother-land of alchemy, during the early centuries of the Christian era, alchemistic doctrines were propagated by the University of Alexandria. These doctrines were absorbed and cultivated to a marvelous degree by the Arabians, who over-ran Egypt in the seventh century, and finally during the Middle Ages penetrated to France, Italy,

Germany, and England, and held sway even to the sixteenth century. The object of the alchemists was to convert the base metals into silver and gold—to 'enoble' the base metals. Hence there was a good deal of mystery attached to the art, and the word 'chemistry' today still preserves some of its early significance. Cham or chemi, the name of Egypt, may also be translated to mean 'black,' and we therefore have the 'Egyptian Science' or 'black art.'—Charles F. Chandler.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

A Make-shift Stamp-Mill.

Specimens sent by A. M. F., of Sierra Mojada, Mex., have not been received.

F. L. S., of Spokane, Wash., sends a specimen of black Tourmaline in radiating branches, with Magnetite grains.

A specimen of quartz-garnet rock with oxidized pyrite and chalcopryite was received from J. C., Fairview, Nevada.

W. S. L., of Silver Peak, Nev., sends: No. 1, massive Barite; No. 2, impure Barite with Limonite; No. 3, black Calcite.

C. H. W., of Grizzly Flats, Cal., sends: No. 1 and 2, compact Mica-Chlorite Gneiss or Schist; No. 3, rock decomposed into clay.

Three specimens, marked A. B. C.,

are: A, Quartzite with manganese stain and Rhodonite; B, Serpentine with native copper; C, Diabase with native copper.

The rocks from F. G. W., of Denver, Colo., are: No. 1, Feldspar-Porphry; No. 2, Rhyolite, somewhat chloritized; No. 3, Quartz-Porphry; No. 4, Diorite.

Specimens from Whitebird, Ida., marked E. W. S., are: No. 1, Serpentine; No. 2, Basaltic Dike with native copper; No. 3, Talcose rock stained by the red oxide of iron.

Specimens marked A. B. C., from Battle Mountain, Nev., are: No. 1, Rhyolite; No. 2, Metamorphic rock, serpentinized; No. 3, Quartz-Porphry; No. 4, Hornblende-syenite.

Weight of Water per Cubic Foot.

Contributed to the Mining and Scientific Press
By C. D. DEMOND.

The accompanying table has the merit of affording data to temperatures above 212° F, the point at which the ordinary tables stop. It is, therefore, especially useful in

TIMBER IN ECUADOR.—Ecuador's timber resources are not considered superabundant. The better classes of wood, the kinds and qualities most desired for local building and construction purposes, are found in limited quantities, being too scattered, when found in accessible districts, to encourage the building of sawmills for the purpose of exploiting such districts and building up any-

WEIGHT OF WATER PER CUBIC FOOT

Calculated from the following data:—

$$\text{Sp. Gr.} = 1 - \frac{(t-4)^2}{(94.1+t)(703.51-t) \cdot 1.9} \qquad t = ^\circ\text{C}$$

1 cu. dm. water at 4°C weighs 999.96 grams

1 cu. ft. = 28.3170 cu. dm.

1 kilo = 2.20462 lbs.

The above takes no account of the compressibility of water. Under the conditions in a steam boiler this is only 0.005 % per atmosphere, which is less than the error in determining the water content.

determining the weight of water in a boiler under steam. The figures for temperatures below the ordinary boiling point hardly differ from those given in other tables.

Tire feverish haste attending leasing in rich ore is well exemplified at Goldfield. Boilers, hoisting engines, and head-frames have in certain cases been erected in the short space of two weeks. Owing to the present difficulty in disposing of ore to the smelters, Goldfield lessees have been forced to either build new ore-bins or to construct platforms on which to pile the ore as they mine it.

thing like a paying industry. It is said that east of the Andes Mtn., and in other inaccessible districts in Ecuador, good grades of various kinds of timber are found in abundance, but until some means of transportation is provided these vast forests will remain practically untouched. The names of the most useful and desirable woods found in this region are roble, figueroa, guayacan, mangle, laurel, balsamo, palo de vaca, pechiche, guachapeli, amarillo, moral, caracoli, cedro, algarrobo, and madera negra. For the frames of buildings guayacan, roble, mangle, guachapeli, and figueroa are used.

Economy of Power in Crushing Ore.

Written for the MINING AND SCIENTIFIC PRESS
By ERNEST A. HERSAM.

This article is intended to direct a more general attention to some of the principles that underlie economy in ore-crushing and pulverization. It is not so much intended to present anything radically new; the purpose is rather to indicate, in a plain sort of way, the direction that progress is taking, and to throw emphasis upon some of the principles that seem to lead most directly to the greater economy of the future. As industry grows, so the pulverization of rock becomes more important. The extent of such work must be dictated by the markets, but in producing the result it is well to be sure that we have advanced the standard as far as it will go to the frontier of the unknown. We cannot judge our present practice entirely by the profit won.

It is important to distinguish between that part of the work that is necessary, and that part in which power is lost as friction and in other ways.

The energy consumed in crushing, though apparently an unavoidable constant, is variable. This is not due entirely to a difference in hardness of the rock. Hardness, it is true, represents the resistant quality against which the forces must be directed, but there are other qualities of the ore and conditions of doing the work that so influence the results as to make hardness a subordinate feature. Lamination, crystallization, and many other physical characteristics may have so pronounced an influence as to render misleading a comparison based on hardness alone. Identical minerals show variable properties as they occur under different conditions; and a given ore of a certain place may be entirely unlike an ore of the same name known elsewhere. When a soft mineral occurs closely associated with a hard one, the soft mineral, even though present in but small amount, offers a line of less resistance to crushing, and the fracture, passing through the soft mineral, leaves uncrushed the hard constituents until the size is made so small as to require also the reduction of the hard particles. Thus coarse crushing may be done easily, sometimes, whereas positive and uniform fine crushing may require much more than a proportionate expenditure of energy.

The size of the fragments before they are crushed, compared with the size of the particles produced by the process, is, of course, in crushing, the measure of the useful work accomplished. The type of machine used, however, and the way of using it, has much to do with the power actually consumed. The energy required is in no case easy to predict definitely, nor is it at once learned by ordinary means of measurement. Some of the power is wasted. Only a part can be positively accounted for; and the part that has produced some telling effect can be learned only by paying attention to the variety of sizes in the particles of the product, and going into matters of measurement in a way that practical needs and immediate purposes rarely permit.

The total power required to crush and pulverize ore increases rapidly as the size is made smaller. Sizes often are expressed in maximum diametrical measurement, as determined by sifting; and to crush a ton of quarter-inch ore, for example, to an eighth-inch size, requires much more power than to crush the same ore, if of half-inch size, to a quarter-inch size—the diameter, however, in either case, being reduced one-half. Power thus becomes a heavy item of cost when a process requires an extreme pulverization of the ore, and this becomes prohibitory with a low-grade ore where power is costly. A small amount of fine dust is found present in any crushed product. This is more serious than is realized. Not

only is the fine ore found unsatisfactory for some subsequent process, but in producing it power has been wasted.

Some of the energy is lost in doing useless work, in crushing and pulverizing, despite every precaution. Friction between the particles of ore, and in the bearings of the machine, and a general loss of power in transmission all along, claim a share of the power. The ore deforms under stress, and this consumes power. Though the simple work of breaking the fragments apart is the only purpose sought, this work of deformation cannot be avoided and must be done before the rupture of the fragments begins.

The force resistant to crushing is simply the cohesion of the mineral; but to overcome this force effectually, sufficient energy must be expended to do, not only this one thing, but additional work as well. The forces are badly directed for a purpose so definite. Instead of pulling the fragments asunder, our machinery squeezes them the harder to break them; and we are obliged to trust the forces, somehow, to find their way around to break whatever rock they can. Machinery is not capable of handling the pieces separately. No frictionless device can cut each piece in two and give to each the measured touch to fracture it. Shearing becomes confused with compression; compression in part becomes tension; and crushing becomes an indefinite action in which only certain resultant forces prevail.

In the jaws of an ordinary type of rock-breaker, the small fragments of ore that result from the first of the thrust, becoming packed and compressed, are not at once disengaged. These are not in condition to receive further pressure until released and re-arranged. The ore so enclosed—pulverized, but retained—under the increasing pressure of the approaching surfaces, instead of being crushed, is partly rubbed and displaced along lines of less resistance. Many pieces of the ore, moderately fine, are in contact; and rubbing upon one another, they become merely abraded; and in doing so they consume energy by producing dust and heat from the friction.

In order to see more clearly the manner in which the power becomes distributed and finally consumed, it is best to consider separately the different directions in which it may go. All the real losses sooner or later appear in the calorific form of heat, unwanted and perhaps unrecognized. The power utilized, on the other hand, expended in overcoming the cohesion of the ore in breaking particles apart, is used in another way. This part is measurable as work done, not as heat lost, or some wasted form of energy, and this part of the power can be accounted for in the reduced size of the ore particles.

First among the general losses is the power lost as pure friction. Friction can be either in the machine, in the ore, or even, when regarded in a certain way, within the body of the single pieces of the ore itself, as a kind of plastic deformation. All these true frictional losses are encountered throughout. They extend from the shafting and belting, which convey power from the prime mover, to the ore itself at the moment of breaking. Thus, friction must be considered as unavoidable as any part of the work done, but it is a part that produces no desired effect, and first indicates a lack of economy, due to improper construction or imperfect conditions.

The *second* cause of loss arises from power given out in vibration in the foundation and elsewhere around the machinery, in supports and hangers, and disappearing in many ways. This energy is scattered in every direction. Foundations themselves, in some cases, consume much power; and the constant vibration everywhere, from the

ground up to the dust-covered cobwebs on distant rafters, all are taking power to maintain the motion. Vibrations of other kinds than this, through the air as well as through the foundation and supports, take away a small part of the energy constantly. Were other more trifling losses to receive separate attention, there could be included sound waves, heat waves, air pulsations, and even light, electricity, and other forms of energy, resulting from an unstable position of the pieces of ore in the machine, or caused elsewhere, as by the jarring of supports and foundations. Such wasted forms of energy being in part the result of friction, and in part of impact, are found everywhere, where there is motion, from the shafting, bearings, and belting, to the mass of ore itself. For the most part, however, the losses occur within the ore that is undergoing crushing.

Third among the general losses, is that due to the unavoidable deformation of the ore. This is not precisely a part of the general friction. It is work done in the interior of the unbroken fragments, and is over and above that work which should be necessary to overcome mere cohesion of the molecules in producing an actual rupture of the particles. It is the way in which much power generally goes; and although in many cases it is a loss that can be much reduced by taking advantage of the natural conditions, there is no hope of avoiding it entirely.

Fourth among the general losses could be named that which results from producing dust or fine below the size sought. The extent to which this becomes serious depends upon the subsequent process of treatment. To a certain degree, the production of dust signifies actual work done, however fine the dust may be. It is often to be regarded as work done improperly, however, if not an entire waste of the power expended upon it.

Thus seen power suffers loss in many ways. Although the purpose is to produce the single effect of crushing, by overcoming the cohesion of the solid ore, removing the fractured pieces from the field of intense attraction, the actual thing done is something quite different, and the resistance encountered is greater than should be necessary for doing that one thing alone. The energy so distributed can be considered as follows:

ENERGY EXPENDED IN CRUSHING.

IN THE MACHINERY.

In transmission to the machine:

- Friction in the bearings.
- Friction in the flexible belts, drives, etc.
- Circulation and friction of air at all moving parts.
- Forms of energy other than heat, of minor importance (electricity, etc.).

In the machine and foundation:

- Friction in the bearings.
- Air-friction and circulation.
- Tremor and vibration through foundations.
- Forms of energy other than heat, of minor importance (sound, etc.).

UPON THE ORE.

Between the fragments.

- Friction, resulting in heat.
- Numerous minor losses (sound, light, etc.).

Within the fragments.

- Plastic deformation.
- Unrecovered elastic deformation.
- Breaking.
- Excessive breaking, producing dust.

The friction of the machinery depends in general upon the construction of the machine and the condition in which it is kept. On the whole it is relatively a small part of the entire loss. Crushing machinery is not dif-

ferent from other kinds in principle; the same loss of power could occur in conveying motion for any purpose. The loss, however, would be increased two or three times by bad management or neglect, or correspondingly reduced by care and careful construction. Matters that should not escape attention, but that are neglected sometimes in regions remote from supplies and inspection, are: Protection of bearings from dust, the use of suitable lubricants and of proper belting, the alignment of shafting, the wear of gearing, and the care of bearing parts. Correct construction in the beginning often saves much cost in the end, but no construction can withstand ill use or neglect.

There have been cases where a change of lubricants has reduced the loss of power 30%, although conditions had been supposed correct before. The change of temperature between winter and summer has its influence, and though the power lost in this way is too variable to state definitely, it is important if lubricants are not suited to the climate and the season. Whenever a bearing is running hot, it represents power wasted. To run bearings even perceptibly warm, and particularly in cold places, is too costly to go unnoticed. When machinery is first started it does not run easily. This is influenced by the nature of the lubricants, the load, the condition of the belting, the dust, the duration of a previous period of idleness, and other factors. In the mill at the University of California, a good idea of the requirements of the different parts of the shafting and the varied work of different machines was obtained by taking periodic readings of a Thomson recording watt-meter, measuring the electric power used.

With good construction and management the power lost through friction in the machinery may be made less than 10% of that expended in other ways. It is a visible loss many times, and is one evident to the mechanic.

The loss of power among the ore-particles is much greater. The actual loss is mostly in some form of friction; and this is multiplied by an improper use of a machine. It will be found in any case to vary greatly with different rates of speed and with different methods of feeding and operating. It appears in two forms, namely, pure friction, and molecular friction or deformation.

When the disturbances that give rise to pure friction are examined, they are found to be more than surface deep. Surface friction is accompanied by strain and deformation beneath the surface. This consumes power in the molecular re-arrangement which, if permanent, often manifests itself as heat that appears to come only from the surface action. The ore is constantly undergoing some kind of frictional loss, and some of this takes place in the interior of each piece before it actually breaks, while some is among pieces after rupture has occurred.

All such friction is lessened by a free discharge of the crushed ore as it becomes reduced to the size wanted. This condition is difficult to obtain. To crush ore, the masses must be retained between the approaching surfaces that administer the force; but while too great an amplitude in the motion of the pressure surfaces tends uselessly to compress the fragments, grinding these upon one another, and distributing the force in many directions, too little amplitude, on the other hand, fails to do more than deform some of the particles, and failing to break these, it wastes whatever energy is so expended. In a reciprocating jaw-crusher, at each revolution, whatever the amplitude, the jaws are certain to come to rest against the elastic strain of ore. The power must suffer loss each time the pressure is applied and released. Thus the loss in working would be most reduced by having exactly the right amplitude for the quantity of ore retained between the jaws at any one time, and by having

sufficient voids between the pieces to provide a place for the crushed particles to occupy as soon as produced. This can be done by making the size of the original pieces uniform and comes from sizing before crushing.

Deformation is in part the cause of surface effects. It is the adaptation of the ore, under stress, without breaking, to new positions, forced by the pressure. It is a great consumer of power, varying with different kinds of ore, different rates of speed, and according to other conditions. In the amount of power consumed by deformation, the time element plays an important part. Give the ore time and it will bend or yield appreciably in any direction, tending to remain in the shape that suits the pressure upon it. Strike it a smart blow, allowing it no time to do this, and it will break always, when the blow is sufficiently forcible to correspond with the size of the fragment.

Ore cannot be worked under pressure like a plastic mass, of course, but there is a tendency for it to do this, and it is this quality that consumes the power. When no longer able to endure compression the ore breaks, but before it does so, it takes up energy in the slight alteration of shape, and the power consumed is the greater for the very difficulty with which it yields. With plenty of time many kinds of rock would bend under stress, and even to a greater extent than brief tests would show them capable of doing. It would be illustrated in a much exaggerated way by warmed glass, or a stick of plastic wax, which gradually would yield without breaking, changing its shape, or bending double if necessary, to occupy a position of least strain. Strain the substance suddenly, however, and it breaks.

There is, to be sure, a limit to the possible shortness of duration, or practical rapidity of motion, for any material to adapt its molecular condition to new needs; and along with the time must be considered other important and obvious factors (the temperature and the pressure applied) but the deformation is in a great measure a question of time, and the elastic limit and breaking strength are in many ways dependent. The study of explosives and of blasting, a knowledge of projectiles and of the results produced by their impact, and even a study of the rapid impact pulverizers, all bring into the consideration a time factor.

Experiments to show the definite effect of speed in crushing have not been numerous. The advantage of high speed, however, has been shown in many cases. Much has been learned already by experiment regarding the viscosity of solids, but this is not so well correlated with what is known of the energy required to crush them. The possible practicable variation in velocity is small. The work can not be instantaneous and neither must it be prolonged. The economy in certain impact pulverizers, and the advantages of high speed in numerous other machines would make it desirable to know more definitely about the power that is consumed by viscosity, and to learn the difference between this and the loss through elasticity, and to know exactly the part consumed by the fracture of the ore. All that can be said now is that much additional total power is required in running slowly upon certain kinds of tough rock; but, on the other hand, brittle or highly elastic rocks show little compensation for the mechanical loss there is in high speed.

The importance of a correct velocity can be learned even by working with a hand-hammer. Selecting a hammer that is a little too heavy for use upon rock that is tough, a man finds it difficult to obtain a satisfactory return for his labor. The same rock with the sharp quick blow of a lighter hammer, in the hands of a man properly skilled, shows a different result. The difference

is not so much in the energy expended. It is in the speed of the blow. There must be a suitably high velocity to accord with the size of the fragment and the distance through which the rupture is made.

Tests of consumed power, measured by the effects, are difficult to make with precision. The measurement must be made upon irregular fragments of rock, and upon a crushed material in a form difficult to sort and measure. The product, like the original material, consists of particles of many different shapes and degrees of hardness. It is not easy even to learn what part of the power has been used in producing dust, distinguishing it from that lost as mere friction, because dust is difficult to collect, to size, and to measure. Each different size of particles represents the consumption of a definite proportion of the total power applied, but since each size must be calculated separately, it must be screened, collected, and considered by itself.

For some purposes all power that goes into the production of dust is lost. In other processes dust is of no injury, as long as all of it is recovered; and in some cases the production of dust may even be sought; but in any case, to learn of the hardness of the ore and the consumption of power upon it, the dust must be collected, and this must be sized, weighed, and calculated for the power it has consumed. Sometimes in rough crushing this dust may comprise two or three per cent by weight of the crushed product, and the power it has consumed is shown to be large when calculated according to its size and the surface it represents.

Besides the plastic deformation there is still another important form of deformation sometimes called elastic deformation, in which the ore alters and then again regains its shape. Ore does not retain or consume power in this respect that it does not again give back when the pressure is released. The return of the power, however, may come at such a retarded time or be in such a direction as to produce less effect than if the elastic deformation had not occurred, and this dispersion of force, rather than the resistance to the original pressure, is seen to be the real cause of loss of power. There is always the possibility of utilizing an important part of the power that expends itself upon elasticity. The energy is stored and exists as an elastic strain. It is unlike that which overcame plasticity, for this consumed power and produced heat in making a permanent change of shape, while elasticity produced but little heat, reserving the energy to be given out again in a kinetic form.

Simple inspection of working machines shows how this elasticity of the ore yields energy in an ineffective way. Consider the jaw-crusher, for example, or one of the gyratory types. In these machines the motion is relatively slow. Under this action, an elastic fragment such as a piece of quartz, is compressed more and more by the jaws of the machine until finally, unable longer to withstand the stress, it breaks. As it does so, the balanced forces in the elastic strain of the particle are upset suddenly, and the whole fragment flies into many pieces by the release of the first rupture, and work is done by the energy that was reserved in the elasticity of the rock.

The loss of power through elasticity will be seen to be different in the different types of machines and under the different velocities of operating. Some crushers minimize this loss. Others recover power from elastic strain, but are wasteful of the plastic deformation by their slowness of motion. All rapidly acting machines, as a rule, are economical as far as plastic deformation is concerned. With elastic deformation this may or may not hold true, as will be seen. Also in a comparison of grinding machines with crushing machines, the difference between elasticity and plasticity of the ore must be carefully

observed. True crushing devices are well suited to contend with elastic deformation, whereas they are not always best when the deformation is of the plastic kind. Thus impact pulverizers have their place, and rapid stamps, deriving their required impact from high velocity rather than through ponderous weight, are effective as crushers for certain kinds of ore. Higher speed in rolls and in all classes of crushers is desirable, up to the point where greater wear and heavier loss comes from the mechanical difficulties due to high speed. The tendency of improved construction has been to increase the speed. Better mechanism, improvements in bearings and means of lubrication, are making a speed possible now that once would have been considered impracticable.

In the stamp-battery it is seen how the work done upon elastic deformation is not well recovered. Whatever the depth of the ore upon the dies, or whatever the weight of the stamps, they are certain at each drop to come to rest against the elastic pressure of the ore. The rebound of the gravity stamps, with an interval of rest necessary for irregularities and contingencies is not recovered again. In rebounding the stamp does not acquire sufficient kinetic energy to be effective when dropping, nor does the rebound occur at a time favorable to aid in elevating the stamp, allowing the interval of rest necessary in a gravity stamp for the cam, with a slight variability in the power. Direct-acting steam-stamps make use of these forces by their rapid action, but in mills where battery amalgamation must be practiced these rapidly reciprocating appliances cannot be used to advantage.

Jaw-crushers gain somewhat by the elasticity, as against the plasticity, of ore; rolls and gyratory crushers also recover much of this elastic force. Tube-mills, *arastres*, and grinding machines, on the other hand, are not well devised to distinguish between the quality of elastic and of plastic deformation except in so far as the elastic deformation is accomplished by a quality of brittleness, or a narrow range within the elastic limit.

The Huntington and other centrifugal roller-mills are economical in this regard. By reason of their construction it is seen that the elastic reaction occurs at a time and in a direction to be effective in propagating a motion in a direction that aids the forward movement of the rollers, and in a manner to replace some of the power that would be necessary were plasticity, instead of elasticity, the restraining quality.

Friction within the ore is variable in different machines. All pulverizers in which the crushing surfaces, the jaws, liners, mullers, or moving parts slide over one another in place of approaching in a direction normal or perpendicular to their surfaces, fail to escape a heavy loss of power through friction and wear. It is necessary to distinguish between crushing action and grinding action by exactly this difference. A grinder is a machine which compresses the ore between surfaces moving tangentially or sliding over one another. A crusher compresses the ore between surfaces approaching normally or nearly so. Both effects, crushing and grinding, occur side by side to some extent, in all reducing machines, for it is not possible to direct a force into a mass of ore to produce motion without scattering the energy into a great variety of tangential displacements. In certain types of machines, however, the crushing feature is brought out as much as possible, and in others grinding predominates. In grinding machines the rupture of particles does not penetrate so much into the centres of the ore-pieces. In place of this, the tangential direction of motion, rubbing along the surface, or causing rotation of the particle, tends only to abrade the exterior, and in so doing tends to produce dust and waste power as friction.

Extremely fine pulverization requires these tangential devices in practical machines. With fine sizes the tangential motion is not so serious. Unevenness in the texture of a wearing surface furnishes innumerable places of lodgment opposed to the direction of motion. Such places are large in size compared with the size of the small particles, and their great number results in countless applications (in a small way) of local normal forces, which hold and break the small particles so as to simulate crushing. It may be said in favor of grinding action for fine sizes, that any attempt to pulverize ore finely in true crushing machines requires thicker layers of the pulverized masses to produce a satisfactory output at a reasonable speed, while within such masses a grinding effect is produced which the very principle seeks to avoid. True crushing practised upon fine sizes brings out more seriously the elasticity of the liners, since these crushing surfaces are exposed to a pressure that is intermittently applied. In principle, however, the effect of crushing and not of grinding is to be sought, and always this is desirable for the coarse sizes.

Tube-mills and ball-pulverizers, by their action, become for the most part types of grinding machines. When the construction or operation provides for a drop-action of the balls, pebbles, or unattached parts, so that in rotating, these fall upon one another, or upon the lining, then the crushing effect begins to appear. However, the elasticity of the pebbles, or the balls, or the elasticity of any substance used in the liners, limits the economy of the crushing principle applied to extremely fine sizes. When the size of the particles of ore is thus very small, then the force to overcome the elasticity of the pebbles or balls becomes relatively great and this elasticity consumes much power compared with the crushing work actually done upon the ore. The hardest and most resistant material that can be obtained, for this reason, is desirable in the construction of machines where ore must be reduced to fine sizes, and especially is this true where slight crushing action accompanies mere grinding.

The final, useful, and necessary part of the work of crushing is that of totally outstripping the force of cohesion of the molecules along the needed lines of fracture, overcoming by distance the attraction that exists in the uncrushed ore. This is the real work to be done. It is against the single quality of hardness that the energy is necessarily directed. The mineralogist's scale of hardness should show this relative factor; it is this quality that would exist if elasticity and viscosity could be disregarded.

While the energy that appears to be exhausted upon the hardness of the rock is varied, in practice, by deformation, which is nearly inseparable from hardness in its effects, there is a final and unavoidable residual cohesion, to overcome which causes rupture, and which is not subject to deformation within the short time-limits of breaking. The energy expended on hardness does not so much depend upon the principle of the machine nor the manner in which the work is done. It is dependent upon the fineness of crushing which represents the effect produced. It can be judged by comparing the size of the particles after crushing with the size before. The energy actually expended in producing this effect can be measured only by taking into account the friction and the deformation that accompanied the breaking under definite conditions.

The real work accomplished in crushing is thus measured by the extent of new surface made. It is desirable, many times, to measure this surface, and to learn by so doing how efficient any process of crushing has been. To measure the exact extent of such surface is not a simple operation. Nothing can be done more than to approxi-

mate it in various ways. Rittinger, Von Reytt, and others have found values in certain cases, but these, while difficult to obtain, have in the end been approximations depending upon certain estimates.

To judge the extent of the surface in a practical way, size the crushed product, and estimate the surface as a whole from the sizes of the screens and the average diameters of the particles. A certain relation exists between the average diameter of the particles, in a closely sized product, and the surface-area represented by such diameters. This relation can be taken as a constant under given conditions. The work done in producing the surface represented by these diameters may not always be identical for different rocks. It will vary according to the kind of machine used, but the work of producing new surface under like conditions in uniform material is necessarily proportionate to this surface and to average diameters.

The unit of work is some certain area of the new surface made, or, more properly, it bears a direct relation to the area of fracture, one square inch of which signifies the production of two square inches of surface which did not exist before the fracture. Such a unit of work, or unit of fracture, can be regarded, if necessary, as though it were united into a certain single large fracture through solid rock, or again, as though a definite volume of ore were reduced from one definite size to another definite size. Practically, rock cannot be cut evenly by fracture. In practice, too, there are found crystals comprising a large part if not all of the rock substance; and there are many irregular qualities, cleavage and seams, that bring out various planes of weakness not encountered until some definite degree of fineness is reached. These planes lead to different shapes of particles, and, in a great measure, are the cause of the different degrees of hardness shown at different sizes. Their effect, moreover, is shown upon the average hardness of the rock.

In dealing thus with irregular shapes and sizes, it is necessary to classify the particles, whatever their shape, by the screens that separate them. In so doing, the theoretical cube would be taken as the basis of the surface measurement. Particles that actually pass rectangular openings differ from the theoretical cube in one way or another. Natural crystals are generally so misshapen and fractured as to give no clue to averages by which surfaces might be estimated. Where, however, a prevailing shape of the particles is so well known and so constant as to make it safe to allow for this quality, a constant factor may be used. Thus the factor k , as will later appear, may be taken to represent the ratio between the surface of a mass of ore, when consisting of particles that would pass a given rectangular screen-opening, and of the same mass existing in such theoretical cubes as should exactly be capable of passing the same screen. Such a relation gives k a value between 1.2 and 1.7.

If a piece of rock, one cubic inch in size, be broken in two with a clean cut parallel with one of the faces, there are made two square inches of new rock surface, and there has been made a cut through the fragment of one square inch in area. This square inch of fracture through uniform substance may be taken as a unit of work, or more properly, a unit of result accomplished. To crush a cubic inch of ore into half-inch cubes would signify producing a fracture in three directions each of one square inch in area, through the one-inch cube. Such a reduction of size represents three square inches of new fracture made, and if a be understood to be the work of producing one square inch of fracture, then breaking a cube into half-inch cubes represents the work of $3a$. If k be taken as a factor expressing the relation between the surface of solids of known average shape to cubes of the

corresponding screen diameter, then $3ka$ is the work of breaking each cubic inch of irregular ore from a size that would pass a one-inch screen to a size that would pass a screen half that diameter. Thus ka , wherever k is constant and known, can be used in place of a , throughout the work.

Without careful sizing it would be difficult to learn how efficiently the work is done. It is too crude an approximation for any but the roughest purposes to learn only the power to crush a given weight of ore down to a certain size. The initial size is important; moreover, an important part of the crushed product could pass a screen much finer than the one stated. When seeking to obtain a product composed, for example, of one-inch pieces, often half or more of the product will pass a three-quarter-inch screen, a third, or more, will often pass a half-inch screen, and much might be even finer than this. Careful examination often shows two or three per cent of extremely fine dust, representing much more power than its amount would first suggest. However difficult it may be to collect and measure the dust produced, it should not be overlooked in estimating the actual work done.

Different kinds of rock act differently in this way. Different crushers produce different results in the uniformity of product and dust that is made. Tough rock, deforming under pressure, will tend toward a large proportion of the maximum sized particles. Brittle ore causes more than a corresponding quantity of fine. The work done, in every case, consists in producing this new surface, however fine the size of the crushed particles. Thus in measuring the hardness of a rock, or the efficiency of a machine, the undersizes can not be neglected.

Since $3a$, in which a is expressed in foot-pounds, represents the work of crushing a one-inch piece of ore to half-inch pieces, it is necessary to extend the expression to represent the work of crushing a larger body of ore consisting of particles of any definite size. This merely is a relation between diameter, surface, and mass; and the expression may be extended in the following way: A cube of ore, one inch in size, broken into any number of smaller but uniform cubes, necessarily will be cut by planes. There are three directions in which these planes will extend, in order to make cubes, making angles of 90° between planes; and in each one of these three directions there will be, not always one plane, but a system of parallel planes, the distance apart and the number of which depends upon the fineness of crushing. The number of parallel planes in any one of the three directions will be $n-1$ if n be taken as the number of pieces produced out of the linear dimension of the original piece. Thus cutting one-inch cubes into eighth-inch cubes makes $n=8$.

The total number of planes made by fracturing the one-inch cube into smaller cubes thus is $3(n-1)$ and each of these is one square inch in area. So when a represents the work of cutting through one square inch of rock, the work of fracturing a one-inch cube into smaller cubes is: $3a(n-1)$.

Applied to any cube, of any size, the value n , becomes D/a where D and a , respectively, are the diameters before and after the crushing. The fracture-planes now are of different area, since the single piece of ore is no longer of unit size. The area of the newly considered fracture-planes naturally will be D^2 , since D is the diameter of the piece in linear units. Thus making one cut through this different-size piece represents aD^2 , of work, instead of a , as in the unit piece, where D had a value 1. The formula applying to a cube of any size (a being the work

represented by a square inch of fracture) thus is seen to be:

$$3aD^2 \left(\frac{D}{d} - 1 \right).$$

The number of such original pieces (whether more than one or less) that could be made from the mass of a cubic inch of solid rock, or in other words, the number of cubical pieces per cubic inch is, $\frac{1}{D^3}$. Here, 1 is the unit of volume, and D^3 is the volume of any of the single particles produced from it. Thus the work per cubic inch becomes:

$$\frac{1}{D^3} \cdot 3aD^2 \left(\frac{D}{d} - 1 \right); \text{ or } 3a \left(\frac{1}{d} - \frac{1}{D} \right).$$

In such a problem, for example, as where a 20-hp. engine is crushing a certain output of ore, reducing it from a 2-in. size to a $\frac{1}{8}$ -in. size, and where it is required to estimate from this what power would be necessary to crush the same 2-in. to $\frac{1}{32}$ -in. size, instead of to the $\frac{1}{8}$ -in. size, the value $3a$ may be taken as a constant where the ore is uniform and the crushing appliance so adapted to its requirements as to be equally efficient. The problem then expressed by proportion is as follows:

$$20 : k :: 3a \left(\frac{1}{\frac{1}{8}} - \frac{1}{2} \right) : 3a \left(\frac{1}{\frac{1}{32}} - \frac{1}{2} \right).$$

In this case $x=84$.

When it is desired to show the power necessary to crush a given weight of ore, as a ton, or a certain number of tons, it then becomes necessary to take account of the specific gravity, S , of the ore, or the number of cubic inches of solid rock contained in a ton of ore, allowing a to stand for the work, in foot pounds, of producing a square inch of fracture. As there are 55,320 cubic inches in a ton of a substance (water) having a specific gravity of 1, there will be $\frac{55,320}{S}$ cu. in. of solid rock represented in a ton of ore. Thus the work of crushing a ton of ore, shown in work units, giving comparative values for a , would be:

$$\frac{55,320}{S} \cdot 3a \left(\frac{1}{d} - \frac{1}{D} \right) \text{ ft. lb. per ton.}$$

or:

$$\frac{55,320}{S} 3a \left(\frac{1}{d} - \frac{1}{D} \right) \text{ hp. hr. per ton.}$$

$33,000 \times 60$

Or simplifying:

$$a \left(\frac{0.08382}{S} \left(\frac{1}{d} - \frac{1}{D} \right) \right) \text{ hp. hr. per ton.}$$

The values of a that will be learned by a careful sizing test will be significant constants, showing the characteristics of the rock. The motion and principle of the machine influence the value of a . The size of the ore pieces giving greater or less opportunity for deformation shows variable effects. The crystalline character of certain rocks brings out different qualities which affect the value of a at different sizes. The speed of running has much effect and should be in accord with the size and quality of the ore. The value found for a , in any given case, makes a standard of comparison, for crushing the same ore to any other size, or in any other machine, and gives a figure that should be equalled or improved in further work upon the same ore, or the reason learned why this cannot be done.

Thus while a stands for a definite amount of work (1 sq. in. of fracture, in foot-pounds) with a given ore, it can not be taken as a constant without regard for the speed, the conditions of temperature and moisture, and many circumstances that influence the hardness or modify the efficiency. The friction and other losses properly

should not be included in the stated value of a . In practically representing it as a result of any test, the friction cannot be entirely eliminated nor the result accurately corrected to allow for it. Running a machine with no load is not an exact measure of the losses sustained in running the same machine while doing its work, and there are numerous other conditions, aside from friction, that have no proper units to express their values. The friction in the ore is dependent upon the mass of material. This is modified by the direction of forces, the amplitude of motion, and the brittleness or the toughness of the rock upsetting the relation that existed at the start. The lowest value for a , however, under the most favorable conditions that can be found, should be an approach to the absolute requirements of the crushing work.

Tests have been made in which ores of various kinds were used, in which the ore was crushed under a dropping stamp, of a known weight, falling through a measured distance, upon a definite quantity of a given ore, prepared and selected of a uniform size and placed in a specially made mortar to receive the single blow of the stamp, and then sized, weighed, and calculated; these tests, or some of them, show a gratifying constancy and give values of a which, for those ores, would seem an ideal to be sought in practice.

It is of interest to observe what values a may have for general ores. These vary so widely between soft rock and hard, and between different varieties of the same mineral, as it occurs in different lodes, that no one mineral can be taken as a standard of comparison. Each ore shows its own minimum value when the conditions for crushing it are made to accord with its needs. Values of a between 2 and 5 are not uncommon. To take some of the common practical estimates, if power is required at the rate of 1 hp. hr. per ton of ore, to crush from 6-in. size to the size of $2\frac{1}{2}$ in., assuming a specific gravity of 3, and regarding k as 1, a value of a is found to be 153. If 30% of the ore exactly passes a 1-in. opening, the remainder passing the $2\frac{1}{2}$ -in. opening as before, a has a value of 120; and if 10% of the whole passes a $\frac{1}{8}$ -in. opening, while 20% is of the 1-in. size, a has a value of 116. Similarly, if it require $6\frac{1}{2}$ hp. to crush a ton per hr. of $2\frac{1}{2}$ -in. ore to $\frac{1}{4}$ -in. size, producing no undersizes, a takes a value of 14.31. The undersizes depend upon the brittleness of the ore and the way in which the work is done. They are variable in amount in different ores, and they should not be approximated by estimates. The work done is often two or more times as great as would be indicated if the largest size were taken as a criterion of the size of the product, and the value of a correspondingly is much smaller than would be indicated if it were so considered. Thus in this latter case such a value as 7 for a might be expected when calculated upon sizes.

The attainment of fullest economy in crushing will be found in a speed that is sufficiently high for tough ore, an amplitude that is adequate for elastic ore, and from a moderation of both speed and amplitude for brittle ore. Whenever the reduction in size is intended to be great, the fine must be protected from further crushing either by water suspension, repeated sizing, or abundant opportunity for rearrangement of the compressed ore by the provision of interstitial space that accompanies uniform sizing. It depends upon producing the effect of crushing rather than of grinding, particularly upon coarse sizes; and of employing hard and non-elastic surfaces in contact with the ore. It demands solid foundations for machinery, care, cleanliness, and protection of bearings, tested lubricants, and the avoidance of all unnecessary irregularity of shape in high-speed running parts designed for the construction.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

SHOE AND DIE OF GRINDING-PANS.—No. 867,989; William Middleton and Hervic N. G. Cobbe, Kalgoorlie, Western Australia.

The combination with the muller plate having slots therein; of shoes having lugs thereon fitting into said slots, and having peripheral flanges that engage the under face of the muller plate and hold the shoes distanced therefrom, said shoes having spaces between them for the circulation of the material, the spaces between the flanges of adjacent shoes at all times being sufficient for the circulation of material to be ground, independent of the wear of the shoes.

HOIST.—No. 868,844; Charles O. Conner, Heppner, Oregon.

A hoist comprising a continuously rotating shaft having a clutch member fixed thereto, a drum mounted upon the shaft and adapted to move longitudinally to engage said clutch member, means for moving said drum, a catch mechanism for holding the drum in contact with the clutch, a tackle winding upon the drum and a catch-releasing mechanism carried by the drum and operated by the tackle.

ORE-CONCENTRATOR.—No. 868,830; Joseph Algert, Denver, Colorado.

In a concentrator, the combination with a bed plate, a frame mounted on said bed plate, boxes secured at predetermined parts of said frame, said boxes being provided with a wedge-receiving recess extending transversely through them, and with a vertical recess intersecting said wedge recess, a wedge in said recess provided with a threaded stem at its small end adapted to extend through the wedge recess of said foot box, a clamping nut threaded to the stem of said wedge and arranged to bear against said foot box, a vertical sliding block on said vertical recess provided with a pivotal centre recess at its top end adapted to rest on said wedge, vertical rods provided with pointed ends supported at their lower ends in the pivotal recesses of the vertically sliding blocks of said foot blocks, a concen-

trating table supported by said rods and wedge blocks, a vertical shaft secured at one end to the discharge end of said table, a stud secured to said bed plate provided with a tapering point pivotally journaled in the lower end of said shaft, a socket plate secured to the under side of said table's supporting frame and provided with a pivotal recess adapted to journal the opposite or upper end of said table's vertical shaft, and means for oscillating said table on said vertical rods and said vertically journaled shaft.

PROCESS FOR THE RECOVERY OF NICKEL FROM ORE.—No. 868,769; Charles H. Ehrenfeld and Jacob R. Grove, York, Pennsylvania.

The process for the recovery of nickel from ore which consists in placing nickel ore within a jar of suitable porous material in operative proximity to an electric conductor within the jar; locating the jar thus charged as an anode in a bath of an aqueous solution of sulphuric acid and a salt of ammonia; locating a suitable cathode within the bath; energizing the circuit and thus recovering the metal.

DREDGING APPARATUS.—No. 868,774; Thomas R. Goth, San Francisco, California.

In a dredger, a rotary snail-shell-shaped digger or excavator having a single projecting cutting edge, and a single inlet opening. In a dredger, a rotary snail-shell-shaped digger in combination with a rotary pipe to which said digger is rigidly secured. In a dredger, a rotary snail-shell-shaped digger having a single inlet opening in combination with a rotary pipe to which said digger is rigidly secured. In a dredger, a submerged or partially submerged pipe, and rotary snail-shell-shaped digger at the extremity of said pipe, said digger having a single cutting edge and a single inlet opening in its periphery.

PRIMING OF EXPLOSIVES.—No. 868,876; Louis Lheure, Paris, France.

An improved primer consisting of a detonating fuse of small diameter embedded in the entire length of the charge and a separate detonator of suitable composition connected with the top end of the fuse by a fuse of smaller diameter, substantially as described and shown and for the purpose set forth.

Testing a Water-Gate.

Hydraulic engineers and mining men will be interested in an extraordinary test recently made at the Sunnyvale plant of the JOSHUA HENDY IRON WORKS upon a 7-in. discoidal high-pressure water-gate. The manufacturers being desirous of testing this, submitted it to an unusually severe trial, namely, that of packing it under high pressure. Selecting one from the stock just finished, the openings were blocked with blank flanges tightly caulked, submitting the valve to a pressure of 200 lb. per sq. in., equivalent to an effective head of 460 ft. As indicated by the position

of the spindle, the disc was at its highest point, the packing was removed and the stuffing-box gland lifted, as shown in the illustration. There was absolutely no sign of leakage at this point, giving conclusive evidence of careful and accurate machining of joints and of the efficiency of the several novel features in its construction. This is a signal victory in the construction of high-pressure water-gates, which will at once appeal to all who have in any way attempted the same test with the old fashioned type. The ease with which these gates can be re-packed under high pressure illustrates the progress made in the manufacture of hydraulic mining machinery, for which the Hendy Iron Works have always been noted.

Commercial Paragraphs.

THE MOORE FILTER CO., of New York, report having just closed a contract with the New Southern Cross Mining Co. at Cable, Montana, for a slime filter-plant.

H. L. ROPER & CO., of El Paso, Texas, are agents for the J. Geo. Leyner Engineering Co. for Arizona, the south half of New Mexico, and parts of Mexico. This company also represents the Crocker-Wheeler Co. and the Elspass Engineering Company.

P. P. CUPLIN of West Bend, Iowa, has issued a pamphlet describing his Pneumatic Prospector, a small machine weighing 10 pounds. This machine has been on the market for a number of years, and the sales have been gratifying to the inventor and manufacturer.

THE ALLIS-CHALMERS COMPANY has opened an office at Deadwood, S. D., with O. F. Purnell as district manager. Special attention will be given by Mr. Purnell and the members of his staff to the sale of mining, crushing, pumping, power, and electrical machinery.

FISHBACK, SCHMIDT & CO., mining engineers and metallurgists, of El Paso, Texas, are fitting and equipping a laboratory and ore-testing plant in that city, wherewith they will be well prepared to make assays, do umpire work, and make tests of ore to determine methods of treatment.

CHISHOLM, MATTHEW & CO., of Colorado Springs, Colo., have recently closed a contract with the Golden Cycle mill for four duplex Edwards furnaces, which are being installed as rapidly as possible. These furnaces take the place of other makes. The four already in the plant when the fire occurred are being repaired, as they were but little dam-

aged by the fire. This makes eight of the Edwards furnaces in this mill.

THE JOSHUA HENDY IRON WORKS, of San Francisco, report the sale of timber-framing machines to Red Metal Mining Co. of Butte, and the United Verde Copper mine at Jerome, and they have another framer nearly ready for shipment to the Anaconda Copper Co. at Butte.

F. W. BRAUN of Los Angeles and San Francisco has been awarded the gold medal at the Jamestown Exposition for the best display of assayers' supplies and chemicals. This firm is now permanently established at 576-584 Mission St., San Francisco, in a new reenforced concrete building.

THE KELLY FILTER PRESS CO. announces that its second 50-ton unit, recently installed at Pearl, Idaho, in the cyanide mill of the Black Pearl Mining Co., is now in successful operation. The purchasers are more than satisfied with the results being obtained from it. After more than a year's incessant labor incidental to perfecting the mechanical detail of an invention such as this, it is particularly gratifying to know that the two first commercial units have, in addition to fulfilling the expectations of the inventor, proved so eminently satisfactory to their respective purchasers; and the company derives no inconsiderable encouragement for redoubled effort from the fact that the Kelly filter today has for its heartiest supporters the Vindicator Consolidated and the Black Pearl mining companies.

Catalogues Received.

THE CYCLONE DRILL CO. of Orrville, Ohio, has issued a catalogue describing their churn-drilling and core-drilling outfits.

THE J. GEO. LEYNER ENGINEERING WORKS CO. of Denver has issued a catalogue describing the Leyner drill-sharpener.

THE B. F. STURTEVANT COMPANY of Hyde Park, Mass., has issued Bulletins 144 and 147, describing their bi-polar, four-pole, and eight-pole electric motors.

TELGEMANN & TORKA, INC., Pacific Coast agents for the Goerz American Optical Co., have issued a catalogue describing their engineering instruments.

THE JEFFREY MANUFACTURING CO. of Columbus, Ohio, has just sent us Catalogue D, illustrating their coal and ashes handling machinery for power plants.

THE A. LIETZ CO., of San Francisco, have issued 'Publication C,' a well illustrated catalogue describing the engineering instruments manufactured by them.

THE UNION IRON WORKS CO., of San Francisco, has issued a catalogue entitled 'The Union Improved Ore Feeders,' in which their improved Challenge and Tullock feeders are described.

THE C. O. BARTLETT & SNOW CO., of Cleveland, Ohio, have issued Catalogue No. 18 describing their line of elevating, conveying, mining, and milling machinery. It also contains some tables useful to engineers.

THE HENDRIE & BOLTHOFF MFG. & SUPPLY CO., of Denver, issues an interesting pamphlet on 'The Hoist Question.' This company manufactures both steam and electric hoists. On page 54 of the booklet it is stated: "We usually carry in stock all sizes of electric hoist frames up to and including No. 6, and with the large stock of induction motors shown on the next page we can usually make delivery upon any complete hoist within three or four days of date of order. This applies to hoists equipped with 440 volt, 60 cycle, 3 phase induction motors only. More time is required for direct current motors. Unless otherwise ordered, hoists will be equipped with steel pinions. Frames No. 1, 2, and 4 are regularly furnished with band brakes, and No. 5, 6, 7, and 8 with post-brakes, but any special equipment can be supplied upon request." The booklet is handsomely illustrated.

Editorial.

THE OFFICE of Mr. F. S. Wayne, our representative at New York, has been moved from 42 Broadway to 500 Fifth Avenue, at the corner of Forty-Second Street, which is a neighborhood easily accessible to mining engineers and near the building of the engineering societies.

SUBSCRIBERS in Mexico write occasionally to complain of the failure to receive the MINING AND SCIENTIFIC PRESS by reason of the fact that the paper is taken from the mail by those to whom it does not belong. Perhaps some of these pilferers will see this and feel a little shame for such a dishonest action. It may be that they think the means justifies the end and that larceny in the cause of technical knowledge becomes borrowing, but we trust that the authorities in charge of the mails will take a more correct view of such petty depredations and see to it that the sneak thieves are punished.

IN THESE gloomy days the spirits of anxious people may be lifted by telling of a kindly act that "shines like a good deed in a naughty world." We are in receipt of a letter from an alumnus of Lehigh, stating that he has learned that the library of that university does not get the MINING AND SCIENTIFIC PRESS regularly; therefore, he desires to pay for five years' subscription in memory of his father, an honored mining engineer, who died recently at Colorado Springs. The son, returning from Peru, says that he "looks forward to continuing the friendships which his father held so highly." Surely this is the sort of feeling that uplifts humanity, and makes men so much more than swift pursuers of the elusive shekel. The spirit of that subscription in behalf of Lehigh is worth more than a Carnegie library.

WE TAKE particular pleasure in giving our readers the address of the Director of the United States Geological Survey. This address was delivered by Mr. George Otis Smith, at Joplin, before the American Mining Congress, and dignified the occasion by presenting important considerations in an authoritative manner. We note a quotation from a reference, made by the present writer when in another place, in regard to the value of the work done by the Survey in the past, and the reading of the address will confirm the general belief that the usefulness of the Geological Survey will be enlarged and strengthened under the direction of its new administrator.

THE ARTICLE on smelter smoke by our friend Mr. L. S. Austin, professor of metallurgy in the Michigan College of Mines, is most timely, in view of further decisions of the Utah courts. Every bit of information on the problem is valuable, for it is of great importance

to the mining industry that smelting operations should not be crippled unduly, while at the same time it is fit and proper that the smelters should cause no wanton injury. We hope to see public opinion sufficiently enlightened not to be misled by pseudo-scientific experts hired by black-mailers. It is to the interest of the whole country that the smelting of ores should proceed and we hope to see it prosper without doing unnecessary harm to anyone.

IN MAY last E. H. Harriman went out of his way to state that in one month 800 broken rails had been discovered on the Union Pacific railroad and there ensued a controversy between the officials of the Steel Corporation and those of the railroad in regard to defective rails. Harriman retorted by giving an order for 150,000 tons of rails to the Tennessee Coal & Iron Company. At that time the control of the Georgia Central railroad, which connects with all of the plants of the Tennessee Coal & Iron Company, was purchased by Oakleigh Thorne, the president of the Trust Company of America. When, recently, the loans of the trust company were being investigated, it was discovered that Thorne was acting for Harriman. Comment is superfluous.

THE AMERICAN Newspaper Publishers Association has made an appeal for the abolition of the tariff on press paper. It is well. An effective way of decreasing the price of such paper would be to curtail the consumption of it, namely, by using less of it for the dreary mess that appears in bulky Sunday issues and by spoiling less of it in the form of a kind of newspaper that neither instructs, nor entertains, but simply debauches the public taste. The high cost of paper may be a 'tax on intelligence' but the plea that the daily newspapers instruct is a tax on credulity.

THE HIDEOUS TRAGEDY of Frank McLaughlin's death will recall the Feather river mining enterprise with which his name was associated. English capital to the extent of \$2,500,000 was spent in an elaborate scheme to dam and divert the waters of the Feather river above Oroville, with the purpose of working the gravel on the river bottom. When the engineering feat was finally performed, it was found that the miners of '49 had worked the ground and McLaughlin's enterprise collapsed. The Big Bend tunnel was another fiasco of a similar kind; in that case a sharp bend in the river bottom was drained by driving a tunnel through the peninsula formed by the winding stream. When completed, at a great expense, it was ascertained that all the best sand bars had been exploited by the pioneers, who built numerous wing-dams, sufficient to enable them to skim the cream of the alluvial deposit. The Big Bend tunnel is now the basis of a water-power enterprise, for a fall of 220 feet is available, enough to generate electric energy at a profit. Major McLaughlin, as he was called, belonged to the type of adventurer, promoter, and politician, with small scruples and a big heart, with queer notions of business and grand ideas of development, fearless and reckless, generous and irre-

sponsible. Such men have done much to develop the West during the frontier stage of civilization, when their qualities look bigger than their faults.

Humors of the Stringency.

HUMOR does not always mean fun; in this case the reference is to a condition of mind and its manifestations in act or word. We have all heard of the cynic who said that Boston was not a geographical entity but merely a state of mind the like of which might exist in a special manner near Cambridge and the Charles river, but was attainable even in Oklahoma or Nebraska. So with this panicky condition that is with us just now, it is a state of mind, cold as the atmosphere that envelops the proverbial Boston schoolma'am, for it has frozen the turbid stream of speculation and brought the ground ice of distrust to the surface of the quiet waters of industry. As in the case of the death of Cock Robin, everyone asks: Who did it? One man says reckless bankers, such as Barney and Morse; some say the stock gamblers, such as Heinze and Gates; others trace it to a deficient currency system and even raise a deprecating glance at the White House. The causes are as complex as the effects. The bursting of a boiler is not to be explained without some knowledge of the theory of steam. We have no special information on the subject and view the collapse of the credit system of a civilized community from the point of view of the average citizen, that is, the man in the street. Whatever the concrete causes at the back of present conditions and whoever the persons that touched off the explosion that reverberated amid the canyons of lower Broadway, it does seem fairly apparent even to the one-eyed that a public lately over-credulous and extravagant has suddenly become timid and miserly. Those that spent are hoarding; those that splashed about in spendthrift fashion are getting out of the water—the water that they failed to turn into golden wine by financial legerdemain. Queer results have ensued. Bonds dropped to a depressing level because it became profitable to sell bonds drawing 4 per cent in order to place the money on call at 10 or 12 per cent. Trust companies gave the names of depositors to the money-brokers so that those who made hasty withdrawals of cash at the time of the Knickerbocker suspension might be invited to release currency. For the latter a premium of 2½ to 3 per cent was offered. This premium drew hoarded money into service. The money-changers did a fine business, giving 2 to 3% premium on currency and paying therefor in certified checks of banks that are members of the New York Clearing House. The currency thus obtained was sold at a premium of 4, and even 5, per cent, that is, at a profit of about 2 per cent, to the banks, which required currency for out-of-town customers, or to employers of labor, who needed it for payroll purposes. Furthermore, the safe deposit companies also gave the names of their customers to the money-brokers, who went to the renters of safes and bid for the currency that had been withdrawn from circulation. Thus it was at New York. Meanwhile nearer

home we had an equally interesting exhibition of the workings of our financial system.

In San Francisco, the legal holidays declared by the Governor of the State have relieved the banks from the demands upon their currency, except for the urgent needs of customers; at the same time, in order to facilitate business and to circumvent those desiring to hoard specie, it has been arranged to issue Clearing House certificates of deposit, the issuance of which entails payment of interest at the rate of 8 per cent for the amount of certificates taken out by each bank. This has lubricated the wheels of industry, which otherwise might have been temporarily stopped. In order to obviate the payment of taxes delinquent at the end of November, such payments being due in currency or its immediate equivalent, the State Legislature has been called in special session and a bill is to be passed postponing tax payments for 60 days. Another effect of the legal holidays has been the closing of the courts, for Justice, like schoolboys, does not work on a legal holiday. By enactment of the Legislature the transaction of judicial business on legal holidays will be legalized and the machinery of the law set in motion.

The Mining Congress.

ANOTHER ANNUAL CONVENTION of the American Mining Congress has been held and we are reminded of the question put to Talleyrand, who, at the close of a protracted diplomatic conference, was asked: What transpired? "Three hours," he said. The meeting was like its predecessors in that it afforded an opportunity to foregather at a convenient centre, in this case, Joplin, in the heart of the lead-zinc mining region of Missouri. The Geological Survey was well represented, the technical press played a prominent part, some earnest men got a hearing, several aëro-thermal orators made things lively, there was much local hospitality, all of which was wound up by the customary exciting debate as to the next place of meeting. But it was no parliament of mining men or any such representative gathering as it ought to be.

The old directorate was re-elected and for a good reason, namely, the coterie in control know that new directors would lose their interest in the work and would be likely to let the Congress die of sheer inanition. The board of directors is not representative; scarcely three of them would be chosen by any large gathering of well-informed mine operators, and at least two of them are a source of weakness to any public organization, but until other and better men are willing to devote their time and energy to the Congress, it is illogical to expect the old guard to resign. There was the usual debate on smelter rates, with the usual inaccurate statements of irresponsible speakers, tending only to befog the real issues between those that sell ore and those that buy it. The mine-operator has nothing to gain from such a wrangle; he can secure just treatment from the smelters only by making careful statements of fact, calculated to win public opinion to his side. The tirades of local politicians will not accomplish this. Another example of

misdirected energy is afforded by the bureau of information, intended to help investors by telling them, in return for a small fee, whether any given mining enterprise is sound or not. Such a bureau can only be conducted by persons themselves not connected with mining schemes and by a staff especially qualified by knowledge of local mining affairs throughout the West—obviously, a large order, far beyond the bounds of the Congress as now constituted. On the other hand, a laudable example of self-restraint was shown in the refusal to recommend a plan for licensing mining engineers, with the notion that such regulation would prevent fraudulent practices. The Congress is in no position to discipline the profession, such a recommendation might come from the American Institute of Mining Engineers; but it never will, for the idea is impracticable. The choice of Columbus as the next place of meeting indicates the wish to make the Congress national in effect, as in name. This ought to win the support of the coal and iron mine-operators in the Middle West, but it may tend further to diminish the attendance of the metal-mining men who have given some support to the Congress during recent years—that is, since Mr. J. H. Richards has devoted himself so disinterestedly to his work as president. Next to the choice of a place of meeting, the most important question is that of a department of mines. Sentiment now favors a bureau, mainly because it is known that the authorities at Washington might be prevailed upon to favor a bureau, while likely to oppose the creation of a new department. Naturally, the President is an important factor and it is known that he favors the consolidation of existing departments rather than the making of new ones, the result of which is to make his cabinet too much like a town meeting. It is understood that Mr. Roosevelt has promised to recommend a bureau with a Commissioner of Mines at the head of it. Senators Heybourn, Hemenway, and Dalzell are willing to help such a plan, provided it is sufficiently comprehensive in scope. The Director of the Survey is not standing in the way, although naturally, Mr. Smith regards the Survey as competent to do most of the things a bureau is expected to accomplish. The idea then would be to enlarge the Survey and convert it into a Bureau of Mines; but we hope, in the best interests of the Survey, that its geological character will not be further diluted and that, on the contrary, any new bureau will take from the Survey its technological and statistical work, leaving its officers free for the particular scientific labors for which they are specially qualified. Messrs. Smith, Holmes, Lindgren, Parker, Siebenthal, and Hess were in attendance at the Congress and added greatly to the usefulness of it; they carefully refrained from introducing any resolutions or influencing action through committees. In this respect they exhibited notable tact. On the whole, the most useful feature of the Congress was the opportunity afforded to explain to the public the character of the work and purposes of the Geological Survey, and the strengthening, therefore, of sentiment in support of scientific investigations that are of the greatest value to the mining industry.

By the Way.

In a recent issue of the *Electrical World*, Mr. John E. Brady has this to say concerning the utility of inventions:

Utility, as predicated of inventions, means industrial value; the capability of being so applied in practical affairs as to prove advantageous in the ordinary pursuits of life, or to add to the enjoyment of mankind. But a mere curiosity, a scientific process exciting wonder, yet not producing physical results, or any frivolous or trifling article of operation not aiding in the progress nor increasing the possessions of the human race, whatever be its novelty, and whatever skill has been evolved in its production does not fall within the class of useful inventions nor become the subject matter of a patent. It has been said that the test whether an invention is useful in the sense of the patent law is not whether it is not mischievous or hurtful, or insignificant, but whether it is capable of use for a purpose from which some advantage can be derived. If it be useful in this sense, the degree or extent of its usefulness is altogether immaterial. It is not necessary that it should be the best means of producing a desirable result, but a means, although inferior to others, of producing it.

Inventions which accomplish definite practical results may nevertheless possess such attributes as to destroy the benefits that otherwise they would bestow upon the public. Inventions whose chief or only value resides in the facilities which they afford to men to perpetrate some wrongful injury either by fraud or violence upon each other, are thus regarded as destitute of real utility. For the same reason arts or instruments which, if completed and in actual use, might be of benefit to their employers, are sometimes held to be devoid of real utility on account of the great risks incurred in their construction. The courts, in their consideration of this subject, must necessarily contemplate the entire scope and effect of the invention, as well upon the maker and operator as upon the consumer.

The acts of Congress which authorize the grant of patents for designs, were plainly intended to give encouragement to the decorative arts. They contemplate not so much utility as appearance. The law manifestly recognizes that giving certain new and original appearances to a manufactured article may enlarge the demand for it, may enhance its salable value, and may be a meritorious service to the public. It, therefore, proposes to secure for a limited time to the producer of those appearances the advantages flowing from them. Utility is not negatived by the fact that the manufacture covered by the patent has no function except to decorate the object to which it is designed to be attached. In such cases utility resides in beauty. Whatever is beautiful is useful, because beauty gives pleasure, and pleasure is a kind of happiness, and happiness is the ultimate object of the use of all things.

It seems that utility is negatived if the function performed by the invention is injurious to the morals, the health, or the good order of society. Thus, an invention to improve the art of forgery, or one to facilitate the spread of a contagious disease, or one to render water or air intoxicating would, of course, be unpatentable for want of utility. The more completely such an invention could perform its function the more objectionable it would be in this respect. In the case of *National Automatic Device Co. v. Lloyd*, the complainant moved for an injunction restraining the infringement of a patent for a toy automatic race-course. The device covered by a patent consisted of a shaft projecting upward from the centre of the base of a circular shell or case, to which shaft a clock-work mechanism was so geared that it could be made to revolve

rapidly by releasing the escapement of the clock-work. On the shaft were mounted two or more radial arms, to the ends of which were attached small top figures of horses. The clock-work was released by dropping a coin through a slot in the machine, whereupon the shaft would revolve, carrying the radial arms with it, for a short time, when the clock-work would be shut off allowing the arms to revolve of their own momentum. The proof showed that the only use to which the device had been put was to install it in saloons and other drinking places, where the frequenters thereof might lay bets as to which toy horse would be the last to stop or would stop nearest a certain designated point; in other words, the machine was used only for gambling purposes. For this reason the machine was held not to be a benefit to society or 'useful' within the contemplation of the patent act and the patent was declared void.

Inventions, the object of which is to afford amusement and diversion, are classed among patentable subjects; but only the mechanical agencies employed can be patented. Under this rule it was held that the patent of the Paul Boynton Co., covering an inclined gravity railroad terminating in a body of water which provided an amusement popularly known as 'shooting the chutes,' was invalid, one of the reasons being that, in view of the old art of launching ships, there was no patentable novelty in the combination of an inclined railway located near a body of water and a boat-shaped car or toboggan, adapted to move downward over the railway and to be propelled forwardly upon the water by the momentum derived from its descent.

In the *Cushman* case, an electrical patent was refused on the ground of the absence of utility and an appeal was taken from the decision of the Commissioner in so refusing. The device for which a patent was sought consisted of an improved method for protecting objects from the effects of lightning by surrounding that part of the lightning rod which is embedded in the earth with a galvanic battery. The reason which the Commissioner gave for refusing a patent was that the intensity of the action arising from either the copper or the zinc plate, or both, in the earth, is thousands of times too small to be sensible as compared with that of a flash of lightning. "The latter has force enough to strike through hundreds or thousands of feet, or sometimes through miles of air. The former has not force enough to strike through the thousandth part of an inch. These are well known facts and the thing must be entirely without practical effect." The court was satisfied that the device in question could be put to no beneficial use and the Commissioner's refusal was affirmed.

The degree of utility is not material and a patent may rightfully issue, so far as that quality is concerned, provided the invention be of some use and benefit. Nor does the simplicity of a device indicate in any way the absence of utility, for this is a recommendation of the usefulness of the article rather than an objection thereto. The existence of utility in an invention is not to be determined by comparing it with other arts and devices, but is rather to be ascertained by an examination of the particular art or device in question. It is not essential to the patentability of a device that it should supersede or be superior to others previously used for the same purpose; nor does the fact that an invention has been displaced by some subsequent invention import a lack of utility. If, however, a patented article rapidly takes the place of all others of similar kind and is successful commercially, these are considerations tending to show that the public welfare has been advanced by its production and that it is characterized by utility within the meaning of the patent laws.

Personal.

A. C. BEATTY is at El Oro.
 PERCY L. FEARN is in Costa Rica.
 JOHN A. REID, of Stockton, is on a visit to this city.
 FOSTER HEWETT has returned to Pittsburg from Peru.
 H. DEC. RICHARDS is here, on his return from New York.
 H. A. SHIPMAN has returned to Denver from New York.
 CARL HOFFMANN is at Boston; from there he will go to Mexico.
 H. W. TURNER is investigating dredging operations at Oroville.
 E. McCORMICK, of Calumet, Mich., is now at Metcalf, Arizona.

FRED. G. FARISH has returned to Denver from the Dutch East Indies.

C. J. BANDMANN has returned to San Francisco from Ketchikan, Alaska.

S. I. HALLETT, of Colorado, is spending some time at Chihuahua, Mexico.

W. H. LANAGAN and FRED L. MORRIS have returned to San Francisco from Alaska.

MARK R. LAMB, of Mexico City, was recently in Parral, Torreon, and Durango, Mexico.

LOUIS HOFER has been placed in charge of the El Palmarito mine in Sinaloa, Mexico.

D. C. BARD, of the Globe Mines Exploration Co., has returned from Coeur d'Alene to Butte.

J. C. BAWDEN has been appointed superintendent of the Standard Consolidated mine at Bodie.

W. E. DEFTY, of Phoenix, is now engaged on examination work in Yavapai county, Arizona.

D. A. MACDONALD, on his return from a season's work in Alaska, is now at Berkeley, California.

E. A. WALL, of Salt Lake, leaves soon for the East, where he and his family will spend the winter.

W. H. LEFFINGWELL is chief engineer for the Mono Power Co., of Bishop, Inyo county, California.

ALBERT I. GOODELL has resigned as manager of the Northport smelter, and has returned to Colorado.

LEON BLY has accepted the position of consulting engineer with the Pacific Power Co. at Red Bluff, California.

J. H. MACKENZIE has been appointed general manager for the Goldfield Consolidated Mines Co.; he is now at Goldfield.

S. A. WORCESTER has completed designs for a new surface plant for the Henry Adney mine at Cripple Creek, and is now at Victor.

F. MORTON CLARK, who is engaged in mining near Culiacan, in Sinaloa, is in San Francisco, on his return from a visit to New York.

J. W. FINCH, lately manager for the Goldfield Consolidated Mines Co., has been appointed consulting geologist to the same company.

F. C. MOREHOUSE is general manager of the Palmilla mine at Parral and of the Mexican Con. M. & S. Co., at Guanaxaco, Durango.

THOMAS KIDDIE, formerly in charge of the Britannia smelter at Crofton, B. C., has been appointed manager of the Northport smelter.

WALTER R. CROSBY, general manager of the Chas. Butters plant at Virginia City, is convalescing from a severe illness at Berkeley, California.

A. L. DICKERMAN, of Colorado Springs, consulting engineer for the J. A. Coram mines in Mexico, was at Parral, Chihuahua, last week inspecting the Palmilla mine.

WALLACE, GLORE & SUMMERHAYES is the name of a new firm of mining engineers and metallurgists, the members of which are H. Vincent Wallace, H. Gordon Glore, and Maurice W. Summerhayes. Their offices are at Nogales, Arizona.

General Mining News.

ALASKA.

The Guggenheims have had 1,500 men working in the Klondike this summer. The Hammon Syndicate, composed of W. P. Hammon and associates, has purchased several claims on Hunker creek and Gold Run creek this summer.—In the Atlin district the Guggenheim steam-shovel and electric haulage plant on Pine creek operated all the season, handling about 2,000 cu. yd. gravel per day. The Pine Creek Power Co. and the North Hydraulic company were still piping in October. The latter company has a steam ditching dredge at work enlarging their supply ditch, but the work cannot be completed this summer. This company has a large reservoir in Surprise lake, about 16 miles long and one mile wide. A dam has been built across the mouth of this lake; the dam holds back enough water to furnish a constant supply of 12,000 in. per day during the season. On the McKee creek the Amalgamated McKee Creek Hydraulic Co. piped throughout the season. The shortage of water on Birch creek hampers work on that creek, but Pearce & Co. made a good clean-up there this season. On Ruby creek drift mining was done by the local syndicate, which obtained control of the individual claims. Weight creek, a south tributary of Pine creek, where considerable gold was mined in the early days of the district, has again produced considerable gold this season. The Otter Creek Development Co. is working the upper part of Otter creek with some success. Some development is being done at the Beavis quartz mine on the north shore of Atlin lake and about a mile from town.—The Guggenheim interests have awarded to M. J. Heney, who built the White Pass & Yukon railway, the contract for the construction of the Copper River & Northwestern railway from Cordova to Copper river. The choice of Cordova as the western terminus, although lengthening the road, avoids the building of a breakwater, as would have been necessary if Catalla had been chosen. E. C. Hawkins will be chief engineer.—At Ketchikan the Cuprite Copper Co., whose property adjoins the Jumbo group on the northeast, is doing considerable development work. The adit, which will cut the vein at a point 180 ft. from the portal and at a depth of 100 ft., is 100 ft. long. The vein occurs at the contact between granite and limestone; the ore is chalcopryrite.—Owing to early snows, all work has stopped at the mines on Porcupine creek.

ARIZONA.

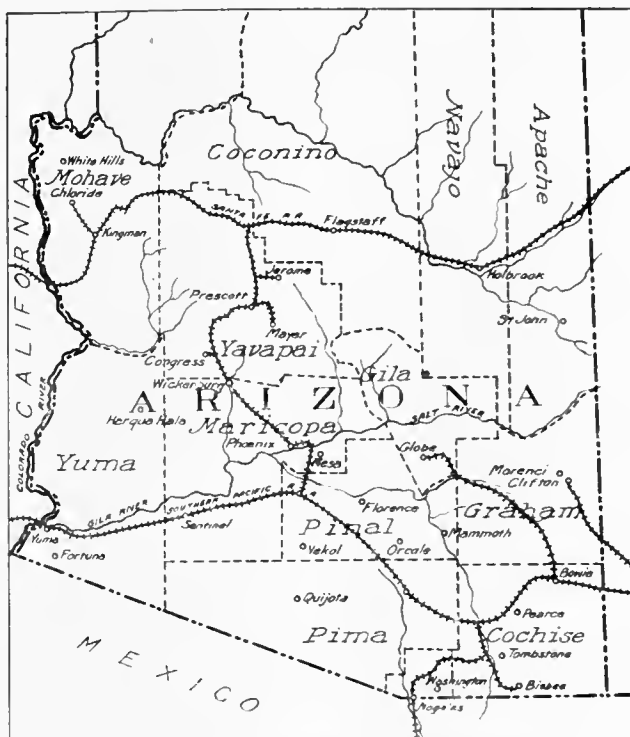

COCHISE COUNTY.

A rich strike of ore was made last week on the 800-ft. level of the Lucky Cuss mine, which belongs to the Tombstone Consolidated Co. The ore is a carbonate carrying much horn silver and some gold; the ore comes from a point fully 200 ft. below the water-level. This new orebody is thought to be the extension of orebody, which made the Lucky Cuss famous years ago and which was lost on the 510-ft. level.—It is stated that the Copper Queen Co. has disposed of the surplus copper which has accumulated during the last four months.—The Copper Queen and the Calumet & Arizona companies at Bisbee have decided to work seven days in the week so that, with the reduced wages, the men can earn as much as formerly. Both these companies are working as many men as before the drop in the price of copper, as they are doing much development. Considerable trouble is being experienced at the Spray and Gardiner shafts of the Copper Queen Co. and the Irish Mag of the Calumet & Arizona with gas, which is thought to come from a worked-out stope on the boundary of the two properties where the timbers have caught fire. Bulkheads are being built to confine the gas to the abandoned area. The bulkheads at the Gardiner have been finished and the gas has been shut off from that mine. Bulkheads have been built on the 950 and the 1,050-levels of the Irish Mag and the gas has been shut off from that mine, but as yet it has not been possible to control the gas at the Spray shaft;

the building of these bulkheads has caused the gas to take a new course in the Spray and now it flows downward into the 600 and 700-ft. levels of that mine. The gas is so strong that miners can only work 10 to 15 minutes when they have to be relieved, in some cases reliefs have been necessary every 5 minutes.—Instead of completely closing their mines, the Shattuck-Arizona and the Denn-Arizona companies have decided to continue development work with a small force.

GILA COUNTY.

Owing to the financial stringency the Old Dominion company is only paying 200 men per day; this began Nov. 15 and it will take several days to pay all the employees. The Old Dominion is again working six days per week and it is expected that the company will soon follow the policy of the Bisbee companies and again work the full week.—The Gem shaft of the Globe Consolidated is now 1,170 ft. deep and a station is being cut at that level; the shaft is to be sunk 30 ft. deeper so as to provide a good sump. At the Mallory shaft a cross-cut is being driven on the 860-ft. level.—Almost half the ore smelted by the Old Dominion

Map of Arizona.

Co. is custom ore, for instance in September less than 2,000,000 lb. of the 3,500,000 lb. of copper produced came from the company's mines. The lower levels at the Old Dominion mine have drained the upper levels to such an extent that the 8th and 9th levels are now quite dry. The ore on the 9th level, discovered over a year ago but not worked to any great extent on account of the water, is quite rich and is self-fluxing. From the winze on the 16th level a cross-cut is being driven to develop the sulphide orebody found on the 14th level.

PINAL COUNTY.

The Hercules & Arizona M. Co., whose property is near Ray, has resumed work with a small force of men.—Both the Oklahoma Copper Co. and the Altai company, have all the machinery installed at their properties near Florence and they will soon be producing.—Some rich copper ore has been discovered at the property of the Sultana & Arizona Co. near Kelvin.—In the Mammoth district, the Calumet & Arizona Co. continues to develop the group of claims, which it has bonded.

CALIFORNIA.

BUTTE COUNTY.

The deep channel has been struck at the Snow mine, in the Kimsheew district. This property is near the Sky High mine, several miles east of Stirling. Development on a

large scale will begin soon. It is stated that the gravel carries \$4 per car. O. C. Barber and F. M. Clough of the Diamond Match Co. are interested in this mine.

INYO COUNTY.

(Special Correspondence).—The present money stringency does not seem to have any great effect on the development of the prospects and mines in this vicinity. Reports of new discoveries are coming in from the White Mtn., about 10 miles east of this place, and some very good bodies of lead ores, principally carbonate, are being opened up.—Crane and Forbes are pushing development work at their prospect as rapidly as possible. They have a body of high-grade carbonate ore; as yet they have not reached the hanging wall.—A. A. Casler, general manager for the Buckeye M. & S. Co., which is operating a property at Poverty Hill, about eight miles south of this place, reports that ground is now being broken for the new two-compartment shaft, which is to be sunk to a depth of 500 ft. This company has a large body of medium-grade gold and silver ore; it is the intention of the company to thoroughly block out this ore before erecting a reduction plant. Mr. Casler states that the company intends to keep a large force of men at work until the two-compartment shaft is completed.—C. E. Cady, who is associated with Colorado Springs people, has a force of men at work on his copper prospect, which adjoins the McAfee mine. This property is opened by an adit over 400 ft. long, which has developed a body of copper ore from 5 to 25 ft. wide, carrying from 3 to 7% copper, and from 4 to 16 oz. silver. It is the intention of the management upon the completion of the present work to patent the property. This is considered one of the best copper properties in this section.

Big Pine, Nov. 15.

The adit at the Killian mine is now 300 ft. long. Everything is in good shape for the winter and the company expects to double the force at this mine soon.—Some rich silver-lead ore has been found on the claims belonging to Bishop and Ellis in Marble Canyon; these are situated between the Black Canyon and Silver Cliff properties.

NEVADA COUNTY.
